These remarks are, I think, specially applicable to a statement made by Schiff at the International Medical Congress at Geneva, to the effect that, as regards cerebral localisation, there was a great difference of opinion between physiologists and physicians; the former being opposed to it; the latter, with an implied sneer at the *practischer Arzt*, being its only supporters. While it is to be hoped that all physicians are physiologists, it is not the less desirable that physiologists should take the facts of clinical medicine and pathology into consideration. Frog and pigeon physiology has too often been the bane of clinical medicine, and tended to bring discredit on a method of investigation which, used properly, we must regard as the sheet-anchor of accurate biological and therapeutical research.

It has been taught since the time of Aretæus, and accepted almost as an axiom by physiologists and physicians that, when paralysis results from lesion of the cerebral hemispheres, it occurs on the side opposite the lesion. This law has recently\* been contested by Brown-Séquard, and a few words are necessary on this point.

Brown-Séquard disputes the validity of the law of cross action of the cerebral hemispheres, on the authority of two hundred cases of paralysis occurring with disease on the same side of the brain. Accepting for the time the accuracy of every one of these cases, what conclusion do they justify? If we compare the relative frequency of cross and direct paralysis, it would be a very low estimate to say that, for every case of direct paralysis, we might cite nine hundred and ninety-nine cases of cross paralysis. Are we, then, on the strength of one contradictory instance, to say that the nine hundred and ninety-nine cases carry no weight? This is what Brown-Séquard would seem to imply; but the logical deduction appears to me to be that, if it had been asserted that the paralysis *invariably* occurred on the side opposite the lesion, then the law is shown, by this one exception, not to be an universal law, but a law admitting of exceptions; an approximate generalisation, instead of an absolute rule; but an approximate generalisation, the validity of which, in any particular instance, would have nine hundred and ninety-nine chances to one in its favour. Certainly the conversion of an absolute rule into an approximate generalisation lowers its practical value; for approximate generalisations are applicable only to numbers and not to individual instances. Hence, in a given case, in which it might be of extreme importance to ascertain whether it was in accordance with the rule or an exception, we might be liable to error, if we had no other means of determining this.

But what would be the practical effect of this, say as regards surgical treatment? Supposing it were a question of trephining (a question which may arise more frequently at no distant date), according to the calculus of probabilities, there would be nine hundred and ninety-nine chances to one in favour of the rule in any given case. Even on this very low estimate, would it be a very hazardous thing to operate, granting the advisability of the operation? I question much if there are many surgical operations undertaken for the relief of internal disease which have better chances of being successful. In life and in medical practice, we have to act on probabilities more than on certainties; and if the measure of our belief be our readiness to act, I think few would refuse to perform an operation with nine hundred and ninety-nine chances to one in favour of its being successful, so far at least as exposure of the disease is concerned.

The practical depreciation of the rule would, therefore, be almost infinitesimal; and, if the new (Broca's, Lombard's) observations on cerebral thermometry are correct, this may be even further reduced. But what of the theoretical aspect of the question?

In man, the cross action of the cerebrum, in reference to motion, is true, with the exception of two hundred cases collected from the remotest antiquity down to the present date. Cerebral paralysis is seen every day; and if cases of direct paralysis were occurring at the present time, we should be certain to hear of them. In the lower animals, every physiologist who has seen paralysis produced by cerebral lesion, has seen it on the opposite side, with the single exception, I believe, of Brown-Séquard.

Such being the experience of physicians and physiologists, it is surely more natural to suspect sources of fallacy, or to conclude that there is something very abnormal, than attempt to overthrow a law which has such a preponderance of evidence in its favour. That direct paralysis may occur I am prepared to admit, not only on the evidence of recorded facts, but on anatomical grounds. To overthrow the absoluteness of the rule of the cross action of the cerebral hemispheres, one well

\* *Lancet*, January 1876.

authenticated case, in which the paralysis occurred on the same side, is sufficient. But we require clear evidence, not merely of the existence of a lesion in the hemisphere of the same side (for, as we shall see, lesions of a very extensive nature may exist in certain regions without causing paralysis), but of the existence of a lesion in what we recognise as a motor region. A solution of continuity of the fibres of the internal capsule, or a complete separation of the corpus striatum from its hemispherical connections, we should look upon as a necessary cause of paralysis, and we should look for it on the opposite side.

If such a lesion could be shown to have existed with paralysis on the same side, I should regard that as a satisfactory proof of direct paralysis. And such seems to have been established by Morgagni. In a case which he had carefully observed, and examined *post mortem*, he was astonished to find paralysis apparently on the same side as the lesion; but, distrusting his recollection and the accuracy of his records, he asked of his students on which side the paralysis had existed. "All in general and each one in particular answered without hesitation that it was the right side [the side of the disease, which was separation of the corpus striatum from the cortex]; and for this reason", said he, "it is clear to me that sometimes the paralysis occurs on the same side as the lesion."\*

I do not here intend to enter on the question whether some apparent cases of direct paralysis may not be capable of explanation in accordance with the usual rule;† but, admitting the possibility of direct paralysis, I would offer a few observations on its mode of causation. In this relation, the recent researches of Pierret and of Flechsig have an important bearing. Flechsig, in his elaborate work, *Die Leitungsbahnen im Gehirn und Rückenmark*, 1876, has investigated the course and relations of the several tracts of the brain and spinal cord, with special reference to their respective periods of development in the human foetus, and to the course and limits of the secondary degeneration which occurs in consequence of cerebral and spinal lesions, according to the researches of Waller and Türck. This is a method which must be regarded as infinitely superior to mere anatomical or histological investigation of the healthy and completely developed cord.

Flechsig shows that the pyramids or pyramidal strands are developed always subsequently to the hemispheres, and from them, and are wanting in anencephalous foetuses. Their connections can be traced above into the cortical regions bounding the fissure of Rolando, and below with the postero-lateral, and partly with the internal aspect of the anterior columns of the spinal cord. These pyramidal strands are subject to very considerable variations, in respect to their decussation at the anterior inferior part of the medulla oblongata, and as to the relative proportion of fibres which proceed down the postero-lateral and antero-internal columns respectively. As a rule, the most of the fibres of the pyramid descend in the postero-lateral column of the end on the opposite side; the rest on the antero-internal of the same side. But occasionally, the rule is reversed; and in one case there was no decussation at all. A similar case has recently been described by Pierret.‡

The strands which are subject to this variation are those which, as we shall see, degenerate in consequence of lesion of the motor centres, and the evidence is of the most satisfactory kind that they are the paths of *voluntary motor* impulses. This being so, we must regard paralysis on the same side as the cerebral lesion as a possible occurrence. How often it has actually happened is another question, which, however, I shall not here attempt to answer.

Various attempts have been made at different times to establish constant relations between lesions of certain cerebral regions and certain symptoms, bodily or mental. Thus Saucerotte, Delaye, Foville, and Pinel-Grandchamp, considered that the grey matter of the hemispheres was specially related to mental functions, and that the medullary fibres and basal ganglia were specially concerned in locomotion. They further adduced cases to prove that disease of the corpus striatum and adjoining medullary fibres and anterior parts of the brain generally, caused paralysis limited to the leg; and that similar lesions of the optic thalamus and posterior parts of the brain, caused paralysis limited to the arm; and that, when the arm and leg were both affected, the lesion existed in the basal ganglia, more in the corpus striatum if the leg were specially affected, and more in the optic thalamus if the paralysis was greater in the arm. Influenced by the imaginary localisation of the sensory tracts in the posterior columns, and by Bell's demonstration of the respective functions of the anterior and posterior roots of the spinal nerves, they regarded the cerebellum, to which they traced the posterior columns, as the seat of sensation. This opinion

was supported by Lapeyronie, Petit-Namur, and others. Bouillaud, from his experiments on animals, and from the facts of clinical research, arrived at the conclusion that lesions of the anterior lobes more particularly caused loss of speech, and in a certain measure gave his adhesion to the doctrines of Saucerotte, etc., respecting the centres of movement of the arm and leg, though he admitted that these were not altogether satisfactory. But he arrived at one other important conclusion which is worthy of special mention. "Even," said he, "though we should admit that certain errors had been made as to the localisation of the seat of the lesions causing paralysis, yet it remains an established fact that there exist in the cerebrum several motor centres. The plurality of motor centres is, in fact, proved by the occurrence of limited paralysis, corresponding to a local alteration in the brain; for it is evident, that if this organ did not contain different centres or conductors of motor impulses, it would be impossible to conceive how a limited lesion could produce a limited paralysis, leaving all other movements intact.

"I am well aware that the preceding propositions appear at variance with the results of experiments on animals. It is certain that after the ablation of the cerebral hemispheres, an animal may walk, run, move its jaws, eyes, eyelids, etc.; and it is not less certain that an alteration of the cerebral hemisphere in man gives rise to a paralysis more or less complete of voluntary motion on the opposite side of the body. Can we refute the one set of facts by the other? No, certainly not. For facts equally positive are not susceptible of refutation. A time will come when new light will dispel the apparent contradiction which exists between them."

Profound and philosophical remarks which to day are amply justified!

The investigations of succeeding years provided many cases so absolutely at variance with the localisation of the motor centres of the arm and leg that Andral, who also admitted that there must be distinct motor centres, "since each limb may be separately convulsed or paralysed", earnestly deprecated premature and hasty generalisations as being highly prejudicial to "la belle doctrine" of the localisation of cerebral functions.†

The doctrine of cerebral localisation has in recent years assumed quite a new aspect, and differs so much from older speculations in the kind of evidence on which it rests, as to be essentially a new growth. Hughlings Jackson made the first decided steps in this direction.

Hughlings Jackson has repeatedly directed the attention of the profession to the study of convulsions of cerebral origin, and adduced many cases and arguments to show that they are dependent on irritation or discharging lesions of certain convolutions, near, and functionally related to, the corpus striatum. As regards the exact localisation of these motor convolutions, he did not, however, underestimate the difficulties and uncertainties necessarily attaching to the rude experiments of disease. "The damage by disease is often coarse, ill-defined, and widespread."‡ But to Hughlings Jackson belongs the credit of having first indicated the motor functions of certain regions and given a rational explanation of the phenomena of unilateral cerebral convulsions. For though, as Charcot shows, Bravais, in 1827,§ described with great accuracy the phenomena of hemiplegic epilepsy, he did not see their true significance or pathology, in which, after all, the discovery lay, and in the light of which the value of his observations mainly consists.

Similar facts have also been noticed and commented on by Bright and Wilks. Indeed, Bright had formed very clear notions as to the pathology of unilateral convulsions, so far at least as their primary causation was concerned, and their relation to lesions of the opposite cerebral hemisphere. "My reason, then, for supposing that the epileptic attacks in this case depended rather on a local affection than on a more general state of cerebral circulation or excitement, was the degree of consciousness which was observed to be retained during the fits: for although we meet with great variety in this respect, yet in two cases which have occurred to me, the fact of the patient generally remaining conscious has been a remarkable feature, while in each the injury on which the fits depended was of a local rather than a constitutional or a general character."||

Wilks, agreeing with these observations, remarks: "For in these cases, the causes being definite and local, an irritation is set up in the corresponding ganglia beneath, and thus the occurrence of convulsions without loss of consciousness is explained."

Hughlings Jackson, however, instead of trying to account for the

phenomena by transmission of some influence to distant motor regions, regarded certain convulsions as themselves motor, and capable of motor discharge by irritation. But certainly, except in the facts so explained, no other evidence could be adduced in support of the direct excitability of the grey matter of the cortex: for the facts of experimental physiology, taking them at their value, were opposed to the doctrine, inasmuch as it had been apparently conclusively demonstrated that none of the usual stimuli of nerves and nerve-centres, electricity included, were capable of exciting movements when applied directly to the surface of the brain.

This dogma was refuted in 1870 by the important experiments of Fritsch and Hitzig, who showed that, though electricity might be applied to *certain* regions of the cortex without producing movements, there were others excitation of which invariably produced movements of the opposite side; and that certain movements could uniformly be caused by excitation of certain definite regions. These facts have now been extended and verified by many experimenters on many animals, and even on man himself.

In discussing the significance of these facts, I wish to restrict my observations to those movements which result from excitation of a certain region of the brain—the region which we term motor—in order to avoid discussion at this stage of certain other movements which I regard as the indications of sensation.

It is not unreasonable to suppose that, on applying irritation to that which is the centre of centres—to which, in fact, all the rest of the body must be considered as peripheral—irritation of the grey matter, even though the irritation might not be confined to it, at least entered as one factor into the causation of the resulting phenomena. Every conceivable hypothesis has, however, been invented to degrade the grey matter of the hemispheres, and to exclude it absolutely from all share in the results; and every attempt has been made to discover somewhere else some organ or organs possessed of all those varied and complex forms of activity which we see excited by our stimulation.

One of the latest of the hypotheses which have been invented to account for the phenomena is, that the movements which result from the application of electrical stimulation to the cortex are due to the irritation of delicate vaso-motor nerves, which penetrate the brain-substance and descend with the vessels from the pia mater.

The functions ascribed to the brain-cells are these: "Besides their power of receiving, transforming, and conveying impressions, it is not unphilosophical to imagine that, having been impressed by a certain irritation, in a certain way, for producing a certain effect, their dynamic state, through nutrition, is shaped into a definite channel for the circumstance; hence the ability of a certain group of cells to produce a definite effect, always constant, under definite stimulation of whatever nature!"\*

As my main object, however, is to discuss cerebral localisation from a pathological point of view, I will not enter at length into the purely physiological side of the question, which I have elsewhere discussed (*Functions of the Brain*). I would, however, call your attention to some recent researches which seem to me to have effectually disposed of the main objections to the view that the phenomena are the result of excitation of the functional activity of the grey matter of the hemispheres. One objection is founded on the impossibility of localising the action of the electric current to the parts immediately in relation with the electrodes; and it is argued that the effects are in reality due to mere physical conduction to some underlying region or regions, which, however, those who employ this argument either will not or cannot exactly specify.

Similar objections were made to Duchenne's theory of localised muscular electrification, and yet we know as a fact that we can by this method throw individual muscles into contraction with the greatest precision and certainty, notwithstanding the extrapolar conduction which pertains to all animal tissues. And it is the great characteristic of the reactions which ensue on the application of the electrodes to the cortex, that the results are uniform, definite, and predictable, when the electrodes are on one region, while there is a sudden transition to another movement equally definite, equally constant, and equally predictable when the electrodes are shifted to a region in immediate proximity to the former. This is a remarkable fact, no longer disputed, which no mere physical conduction can account for, unless we admit a localisation of numerous distinct physical paths, which is but another aspect of localisation after all.

On the conduction theory, we should naturally expect that the nearer we go to the underlying ganglia and tracts, the more readily the effects should be called forth if it were a question of mere resistance of currents. But we find that electrification of the island of Reil, which is nearest the basal ganglia, is absolutely negative; while electrification of

the more distant postero-parietal lobule by the same stimulus produces an immediate and definite movement. Conduction would seem to be put out of court by such facts. And we find, as Carville and Duret have shown, that the intervention of a fluid cyst between the cortex and the basal ganglia is quite sufficient to interpose a fatal obstacle to the propagation of functional stimulation, though not of electrical currents, just as a ligature round a nerve will stop neurility but not electricity.

But the fact on which most reliance is placed as proof of mere physical conduction is that, after removal of the grey matter of the cortex (stimulation of which is the supposed cause of the movements), the application of the electrodes to the cut medullary fasciculi produces exactly the same movement as before.

What, it is triumphantly asked, could more conclusively dispose of the view that the cortex is concerned in the results, seeing it may be removed without prejudice to them? Apparently, those who argue in this manner forget that there is such a thing as a plurality of causes or conditions. By parity of reasoning, we might disprove in succession the motor functions of the corpus striatum, crus cerebri, spinal cord, motor nerves, inasmuch as we can produce all the effects attributed to their activity by direct stimulation of the muscles themselves. But we do not say, when we faradise the distal end of a divided motor nerve, that the resulting muscular contraction is due to electrical conduction to the muscle, and not to neurility or excitation of the functional activity of the nerve. And it is surely not unreasonable to suppose that, after removal of the cortex, the results following application of the electrodes to the medullary fibres are due to the functional excitation of these fibres; and that our electrical stimulation is merely an artificial substitute for that which normally proceeds from the grey matter of the cortex. It is on this point that we have new experiments which, in my opinion, settle the question definitely.

[To be continued.]

## CLINICAL MEMORANDA.

### ACCIDENTAL POISONING WITH THE NITRATE OF POTASH.

EXCEPT in the case of articles of diet in common use, such as shell-fish and mushrooms, or of the substitution of some well-known poisonous herb for one ordinarily employed in cooking, cases of domestic poisoning by accident are generally puzzling at first. The following accurately noted case was forwarded to me by the sufferer, a retired surgeon; and, as the accident occurred through an error in cooking committed with the best intention, and therefore not unlikely to occur again, I have obtained his permission to communicate it to the members of the Association.

In order to make some soup more "strengthening" for the especial advantage of the patient, some liquor, in which a pig's face had been cooked on a previous occasion, was boiled down to a jelly, and added to it. This soup was taken at 2 P.M., and it was noticed to be a good deal too salt. No symptom was observed for three hours, when nausea and griping set in; these continued to increase to the eleventh hour, when some whiskey and nutmeg which had been taken was vomited. There was no bile or anything unpleasant in the evacuation. At the twelfth hour, violent watery purging in large quantity set in and continued for an hour, and the pain ceased. No further symptom occurred, but the patient stayed in bed upon fluid diet the next day. Not until the morning of the third day did he feel a good deal of lumbar aching, which he attributed to the confinement. In the course of the morning, the bowels acted naturally, and he went out of doors. At midday, he took two ounces of Hollands in cold water. An hour afterwards, he passed water, which was coffee coloured from admixture of blood; there was (and had been) no dysuria, or any other fresh symptom. He returned to bed, and the urine having, in the course of a few hours, regained its normal appearance, it was tested, and ascertained to be perfectly free from albumen. He now diagnosed the cause of illness. He stayed in bed upon low diet for three more days; the lumbar aching continued, but the urine remained free from albumen. On the fourth day, he got up, and with one meal took an ounce and a half of Hollands with cold water. This was again followed, within an hour, by hæmaturia, which passed off as before within a few hours, leaving the urine quite free from albumen. From this time, he abstained from spirits entirely, and the lumbar pain gradually disappeared, leaving him in his usual state of health. It is worth noting that the patient observed this lumbar aching to be quite different from the pain caused by lumbago—a disease with which he is also personally acquainted.

# CLINICAL LECTURES ON THE VARIETIES OF PHTHISIS.

*Delivered at the Hospital for Consumption and Diseases  
of the Chest, Brompton.*

By C. THEODORE WILLIAMS, M.A., M.D., F.R.C.P.,  
Physician to the Hospital.

## LECTURE III.—CATARRHAL PHTHISIS.

By catarrhal phthisis I designate a class of cases which may be clearly traced to catarrh of the bronchi induced by cold or damp, creeping down into the alveoli, and thus originating catarrhal pneumonia, followed by implication of the alveolar wall. It is the catarrhal pneumonic phthisis variety of many authors, and a large number of the in-patients and out-patients of this hospital are included under it. Out of one thousand private cases whose origin was investigated by Dr. C. J. B. Williams and myself, no fewer than one hundred and eighteen (nearly twelve per cent.) could be traced to this cause. Family predisposition was present in a few instances, but in a large number it was entirely absent; and, as the patients belonged to a class for the most part exempt from the depressing influences of bad air or scanty or improper food, they may be taken as a proof of the undoubtedly catarrhal origin of a considerable number of cases of phthisis.

Two principal modes of onset are to be noted in this form of the disease. The first is as follows. A patient has an attack of pneumonia, generally one-sided, and not necessarily accompanied by great pyrexia, and for the most part limited to one portion of the lung. He recovers from the attack; but the dulness persists, and there is also some bronchophony and absence of vesicular murmur. He regains his general health, but does not lose his cough or expectoration, the latter becoming purulent; and sometimes the breathing is slightly impaired: though the existence of this last symptom of course depends on the number of alveoli blocked and the amount of surface impaired. The cough and expectoration continue, and are followed shortly by loss of appetite, night-sweats, and wasting. There may also be rise of temperature and pulse; but this is not necessary. The chest is examined, and over the consolidation are detected signs of active disintegration; coarse *râles*, and soon cavernous sounds are audible. In a word, excavation has taken place in the old spot of catarrhal pneumonia. And here let me draw your attention to the rule, that the tendency of pneumonic consolidations to resolve seems to be in the inverse ratio of the fever and constitutional disturbance which accompanied their formation. After an attack of double pneumonia accompanied by high temperature, involving the whole surface of both lungs and threatening the patient with fatal results, resolution is for the most part speedy and complete; whereas a slight and limited pneumonia, involving only the lower lobe of one lung, and hardly giving rise to any constitutional disturbance, is slow to disappear, and sometimes does not disappear at all, but remains a dull spot, the nucleus of future mischief—perhaps to undergo disintegration and excavation. The subjoined is a good illustration of this first form of catarrhal phthisis.

Mary N., aged 39, married, with no children, was admitted under my care into the Hospital for Consumption on July 18th, 1871. Her brother had died of some form of chest-disease. Six years ago, she had pneumonia of the right lung, and was laid up for some weeks, and since that period has had cough. Four months ago, she stated, she caught a fresh cold; and since that date the cough had been much worse, the expectoration muco-purulent, and, for the last two months, streaked with blood. There had also been night-sweats, emaciation, and loss of colour. On admission, her cough was troublesome, with abundant expectoration. The patient complained of pain in the left chest, most marked in the interscapular region. The appetite was moderate; the tongue clean; the bowels relaxed; the catamenia irregular; pulse 92; respirations 40; afternoon temperature 98.7 deg. Fahr.; weight 7 st. 13½ lbs. The physical signs were, dulness over the whole of the right side of the chest, front and back, with bronchophony; some flattening and deficient expansion visible over the upper third of the right front; cavernous gurgle, heard below the clavicle; and coarse crepitation from the third rib downwards to the base, the sounds being more liquid in the upper than in the lower portions. Over the posterior surface, the crepitation was heard everywhere; but it was somewhat finer in character. With the exception of some sonorous rhonchus in the mammary region, the left lung was quite free.

This patient was treated with cod-liver oil, alkaline gentian mixture,

and effervescing ammonia draughts at night, and a generous dietary; and, after three months in the hospital, was discharged "improved", having gained seven pounds and a quarter. The cough and expectoration were less. The crepitation had diminished in extent and intensity; but cavernous sounds were audible over a large surface of the right lung.

This case exemplifies well the catarrhal pneumonic form of phthisis. The inflammatory origin was clearly proved—(1) by the extent of the dulness and bronchophony; (2) by the unilateral character of the lesion; (3) by the history. The absence of any considerable amount of shrinking of the side distinguished it from phthisis originating from interstitial pneumonia, of which we shall speak hereafter.

A second form of attack is the following. The patient, generally middle-aged, has been subject for several years to winter-cough and expectoration; and in many cases there is present a certain amount of pulmonary emphysema. In the summer months, the patient is, as a rule, quite free; but some one winter, owing to being exposed to more unfavourable circumstances than usual, he suffers a more severe attack of bronchitis, involving a larger surface. After the severity of the symptoms has subsided, the cough remains; the expectoration becomes more purulent and abundant; the pulse is quick; and not uncommonly there is a rise of temperature in the evening. The patient loses a certain amount of flesh. The physical signs are at first those of bronchitis: sonorous and sibilant rhonchus scattered over the whole surface of the lungs, succeeded at a later date by bubbling sounds, the percussion being resonant or super-resonant. These signs disappear from the greater part of the lungs, and remain fixed in one portion, either over a whole lobe, or under the clavicle, or at the angle of the scapula, or below or above the scapula. The localising of the physical signs of bronchitis is always suspicious, and more especially so if any degree of crepitus accompany the expiration, thus distinguishing it from the pneumonic subcrepitan rhonchus. Next comes slight dulness on percussion, chiefly to be detected by comparison with the note of the opposite side; or a whiffing sound in situations overlying the principal bronchi, below the clavicle, in the suprascapular, interscapular, and scapular regions, showing that the bronchial sounds are conducted to the ear by some solid medium. Flattening of the chest-wall follows. The next step is increase of crepitation; then the ominous croaking rhonchus; then gurgling, and often the cracked-pot sound. A cavity has formed, and these latter degrees of the destructive process are easily proved by careful examination of the sputum. All these signs may be traced in selected cases; but they are not always present, and even if present, are not always detected; for, on account of the emphysema present, many of them are masked, and consequently overlooked. We often find ourselves listening to gurgle and cavernous breath-sounds where a few days before we heard only sonorous rhonchi and mucous *râles*. The great point in watching the physical signs is to observe whether or no they become localised; for, if they do, we may know full well that the hour of tuberculosis is come.

Let us now take a good instance of this second form of catarrhal phthisis.

Janet S., aged 46, married, a dressmaker, was admitted into the hospital on December 2nd, 1873, with the following history. No consumption could be traced in her family. She had small-pox many years ago, and whooping-cough seven years ago, but recovered without a permanent cough. For the last four winters, she had had a cough, persistent also in summer for three years. During this time, she had lost weight. Night-sweats had come on lately; and at present she had cough in the morning, with yellow expectoration; and complained of pain under both clavicles, felt most on the right side. Tongue clean; appetite good; bowels confined; pulse 70; weight 6 st. 6½ lbs. The physical signs were, slight dulness and crepitation detected in the upper third of the right lung, front and back; crepitation audible over the whole of the left lung anteriorly, and over the upper third posteriorly. The temperature was taken five times a day for a week, from the 14th to the 20th of January, with the following result: Averages at 8 A.M., 97.7 deg. Fahr.; at 11 A.M., 97.9 deg. Fahr.; at 2 P.M., 98 deg. Fahr.; at 5 P.M., 98.3 deg. Fahr.; at 8 P.M., 98.6 deg. Fahr. The course from 8 A.M. to 8 P.M. was, as a rule, subnormal, the average being 97.7 deg. Fahr. The treatment was oil with acid gentian mixture twice a day, an ounce of effervescing ammonia mixture, and five minims of antimonial wine night and morning. She had profuse sweats for a few nights, and hæmoptysis to the amount of half an ounce on February 2nd, but otherwise improved; and on February 26th, shortly before her discharge, she had gained six pounds and a half in weight. The cough was less severe; the crepitation had greatly diminished in the upper part of the left lung, and was less audible in the right lung.

This patient was readmitted on March 14th, 1876, after an interval of two years since her discharge. It appears that she had improved

during the first year, and continued to gain weight; but in the second year she had been attacked with rheumatism, followed by what she called bronchitis. Hemoptysis to the amount of four ounces came on six months previous to admission. The cough had been worse, and the expectoration largely increased. The appetite was good. The temperature and pulse were about normal. The catamenia were irregular, and leucorrhœa was present. The patient had lost eleven pounds since her discharge. Night-sweats were profuse. On examination, scattered crepitation was heard in the upper right lung; and similar sounds were heard on the left side, but to a less extent than when she was in the hospital before. The same treatment was pursued, and she improved until the beginning of April, gaining four pounds. Shortly after this, the cough increased; the expectoration became more abundant; and, on examination of it, lung tissue was clearly detected. On May 22nd, the crepitation was very coarse in the right lung, the patient losing weight; and this was noted again on the 29th. On June 12th, these signs had diminished; the cough and expectoration were less; and the patient had regained three pounds and a half. Her weight was 6 st. 6½ lbs.

Here, then, was a chronic bronchitis extending over many years. On this catarrhal pneumonia supervened, the formation of tubercle being masked by the emphysema; and in time lung disintegration and excavation took place, the date of the latter being after her second admission into the hospital.

It is curious to note, in this variety of phthisis, how little the pulse and temperature are affected; and it is by no means rare to find lung-disintegration proceeding rapidly over a limited space without raising either pulse or temperature.

The pathology is tolerably simple, though, curious to state, much opposition was at first raised to the catarrhal origin of phthisis; and even now some eminent authorities are much opposed to this mode of causation. A catarrh creeps down the bronchial mucous membrane, and eventually reaches some of the alveoli. Here rapid proliferation of the epithelium takes place, which is the more irritated and prone to multiply, owing to the inhalation of some of the bronchial secretion. The alveoli become choked and stuffed with epithelium; and the vessels may be emptied through pressure; ulceration may follow, and the whole mass may liquefy, caseate, and be expectorated. More commonly, however, caseation of the epithelium takes place, followed by absorption of the necrobiotic material by the lymphatics. Thus the alveolar wall, with the perivascular lymphatics, becomes involved, and adenoid hyperplasia (*i. e.*, the tubercle) is the result.

In many of the instances under my notice, there have never been physical signs of extensive consolidation during life; but breaking down of the lung has occurred very rapidly, and cavities have formed in one or more portions; and though the physical examination may teach us much, the only way to be sure of ascertaining that this process is going on is to examine the sputum frequently and carefully.

Most cases of catarrhal phthisis gradually become one of chronic tubercular phthisis, and consequently the *post mortem* appearances do not differ materially from those of the latter variety. In early instances, however, as Kindfleisch shows, where only certain lobules are invaded by catarrhal pneumonia, centres of caseation may be traced in the track of these lobules; and surrounding these, or following the line of the peribronchial lymphatics, are groups of miliary tubercles—thus proving their infective origin.

The principal features of catarrhal phthisis are the tendency to excavation and the comparative absence of fibrosis; and to these are due its less favourable course and more limited duration, compared with that of other chronic varieties, and especially the fibroid. Patients may remain with their lungs in a tolerably quiescent state for years; but when, from some fresh exciting cause, more tuberculation or excavation is induced, there seems to be no limiting power, the lungs become rapidly disorganised, and the patient sinks.

*Treatment.*—This resolves itself into (1) treatment of the catarrh and (2) treatment of the after-lesions. During the catarrhal stage, the great point is to promote expectoration, and thus prevent aggregation of the epithelium in the alveoli and smaller bronchi; but here we are often met with a difficulty in the form of the badly developed chests and weak expiratory muscles of many of these patients, which renders expectoration difficult. The treatment should be that of bronchitis in a badly developed and ill-nourished patient: expectorants of various kinds, administered in a manner not likely to nauseate the stomach and interfere with the appetite, combined with friction of the thoracic walls by stimulating liniments. Some authorities go as far as to recommend emetics; but, unless there was risk of death from asphyxia, I should not recommend them, as they are only of temporary use, and would be pretty certain to derange the appetite. Carbonate of ammonia, senega, compound tincture of benzoin, all do good; but

what I have found most useful has been an effervescing potash draught with five grains of carbonate of ammonia, taken every four hours; because, while it promotes free expectoration and action from the kidneys, it does not upset the appetite. Stimulant inhalations, such as benzoin or iodine or the pinus sylvestris, are reported to do some good; and I have seen fair results from the use of ipecacuanha wine in the spray-apparatus, as advocated by Drs. Ringer and Murrell. Friction of the chest-wall with compound camphor liniment, or with linimentum terebinthinæ aceticum, have also appeared to me to promote expectoration by stimulating the expiratory muscles. If, however, we entertain no doubt that consolidations have formed, we must trust more to general than local treatment, though attention must be paid to both. A generous dietary, including meat three times a day; abundance of milk, which, if taken warm, promotes expectoration; cod-liver oil, with dilute phosphoric acid and bitters; the local application of iodine over the affected side,—are the means most likely to prove effectual.

The climate most suited for these patients has been a matter of my most serious consideration; but a comparison of the results of the various climates in these cases has pointed to the conclusion that a warm moist air answers best. My statistics, as published in my recent Lettsomian Lectures (*Influence of Climate in Pulmonary Consumption*), show that at Madeira catarrhal phthisis fared better than on the Riviera, or in Egypt, or on sea-voyages; and it is probable that this is owing to the air of Madeira containing, combined with warmth, sufficient moisture to render expectoration easy.

## ON CURRENT-MEASUREMENT IN ELECTROTHERAPEUTICS, AND IN THE ELECTROLYSIS OF BLOOD.\*

By J. DIXON MANN, L.K.Q.C.P.I., Manchester.

THE purport of this paper is to advocate a more definite method than the one usually adopted of estimating the dose of electricity administered to a patient. The dosage of electricity is generally recorded by a statement of the kind of battery and number of cells used; as I have elsewhere had occasion to point out, this method is necessarily fallacious. Different batteries have different electro-motive force; and the same battery, from variation in its resistance and from other causes, will evolve more current at one time than at another. A still more formidable obstacle to the estimation of the current-strength by the number of cells used is the variation in conductivity of the patient's skin; not only do different individuals offer different resistances, but the same individual may, on two occasions, vary in resistance to the extent of several thousand Ohms. This variation is principally due to the action of the sudoriparous glands; the drier the skin, the higher the resistance. Up to a certain point, the resistance of the skin diminishes during an application when the electrodes are stationary, the stimulating effects of the current promoting increased action of the sweat-glands.

The amount of electricity administered to a patient is the product of two factors—the electro-motive force of the battery and the total resistance; the formula, as expressed in Ohm's well-known law, is  $C = \frac{E}{R}$ . Now, even supposing the electro-motive force and internal resistance to be constant in all batteries, and of known value, the enormously varying and unknown external resistance would prevent any accurate estimate of the strength of the current being deduced from this formula. By including a galvanometer in the circuit, the difficulty is overcome, the needle being deflected proportionately to the strength of the current; and if the galvanometer be graduated in fractions of the unit of current, the indications will be of absolute current-value. Along with Mr. J. T. Sprague, who possesses the patent right in this country for the graduation of galvanometers in degrees of current and resistance, I have devised an instrument which indicates, in ten-thousandths of a Weber (the British Association unit of current), the dose of electricity administered to a patient. The graduations of this galvanometer, representing actual current-values, are constant for all instruments similarly constructed, enabling the operator to record the dose administered, not relatively, but absolutely; thereby conveying a definite idea of the strength of the current, and placing it within the power of any one using such an instrument to administer an equivalent dose. This instrument possesses, I believe, an advantage peculiar to itself;

\* Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877.

the divisions, instead of following the law of tangents and becoming rapidly closer after the first ten or fifteen, by a peculiar arrangement of the coil and needle, are spread out in the portion of the scale most frequently used, adding considerably both to the ease and to the delicacy of observation.

It is obvious that current-measurement is necessary to develop the therapeutic use of electricity, the action of any remedy being only ascertained by accurate estimation of the dose administered. When the chemical action of the current is solely utilised, as in the treatment of aneurism by electrolysis, current-measurement becomes imperative. The want of definite knowledge on this subject induced me to investigate experimentally the formation of blood-clots by the voltaic current. The experiments were made with human blood and with that of the lower animals, to which various chemical reagents were added to retard or prevent natural coagulation. A few observations were taken with horses' blood, which retains its fluidity sufficiently long for experiments to be made without the addition of preventives to coagulation.

An apparatus was constructed so that two or more platinum or steel wires of equal diameter, placed at equal distance apart, could be immersed into the blood to a known depth. The current, measured by one of my galvanometers, was allowed to pass for a definite time, observations of the current-strength being taken every minute: the resistance ranged from 750 to 2260 Ohms. At the conclusion of each experiment, the clot formed on the anode was thoroughly drained on filtering-paper and accurately weighed. The observations of the current-strength, together with the weight of clot, were then reduced to a common mean, giving the weight of clot formed per minute by a current-strength equal to the one-hundredth of a Weber. The deposit round the cathode, being from more than coagulum, was not estimated. In some experiments, another apparatus was employed. A portion of the aorta of a cow, immediately after the death of the animal, was filled with blood and a needle connected to the anode inserted into it, the cathode being attached to a piece of tinfoil placed on the external surface of the artery.

The difference in the clots formed by relatively large and small currents was ascertained—(1) by taking the specific gravity of the clots in oil, and reducing the result to the usual standard—distilled water; (2) by re-weighing the clots when they were thoroughly dried; (3) by microscopic examination of the texture of the clots after washing them free from corpuscles; (4) by general observations of their consistence and tenacity.

In order to ascertain the effects of variations in the density of the current—that is, the proportion the current bears to the area of the electrodes—two depositing cells containing blood were set up "in series". In one cell, two wires were immersed five-tenths of an inch; in the other, similar wires were immersed only one-tenth of an inch; the current-strength passing through each cell being necessarily the same. The experiment was varied by substituting for the larger wires slips of platinum foil exposing an area of three-tenths of a square inch. The clots obtained were examined after the former manner.

Table showing the Mean Weight and Specific Gravity of Clot deposited per Minute by a Current-Strength equal to the one-hundredth of a Weber. Mean Temperature 69.5 deg. Fahr.

Metal forming Electrodes.	Weight of clot in grains.		Loss per cent. on drying.	Specific gravity.
	Recent.	Dry.		
Platinum.....	.1397	.0333	76.163	1.005
Steel.....	.1092	.0405	62.623	1.140

The conclusions drawn from a number of experiments conducted after the methods above indicated may be briefly epitomised. The rate of clot-formation is in direct proportion to the current-strength. With a complex fluid like blood, there is great difficulty in ascertaining this proportion with precision. Without great care, the means taken to keep the fibrin in solution introduce errors seriously affecting the results. The specific gravity of electrolytic clots is inversely proportional to the strength and to the density of the current. There is, however, practically little difference in the general character of the clot produced within the limits of current-strength usually employed in the treatment of aneurism.

Clots formed on platinum wires were found to be more bulky and of greater weight, but of less specific gravity, than those formed under like conditions on steel wires. The increase in bulk is due to porosity of the clot produced by the presence of free oxygen. When steel wires are used, the nascent oxygen combines with the iron. On reference to the table, it will be seen that clots deposited on steel needles after desiccation exceed in weight those deposited on platinum. The excess in weight is produced by oxidation of the anode, and by the consequent presence of oxide of iron in the clot.

With a weak or medium current, clots formed on steel wires are more friable than those formed on platinum. When the current-strength is great (.05 Weber), the deposit on steel wires is pasty. Platinum clots, when moist, bear a considerable amount of pressure without disintegration; steel clots, on the contrary, break up under moderate pressure; this difference exists in clots produced by medium currents. With the use of steel needles, the current-strength rapidly diminishes, owing to the oxide of iron formed on the anode setting up a counter electro-motive force, which opposes the battery-current; with platinum or thickly gilt steel needles, the polarisation is comparatively slight.

Clots deposited from blood at 60 deg. Fahr. are not so dense as those deposited at the normal temperature (98.4 deg. Fahr.), the rate of deposition being the same.

The practical conclusions to be deduced from these investigations, as regards the treatment of aneurism, are as follows. The current-strength should not exceed .015 Weber. A current-strength equal to .01 Weber produces a firm clot, and may be theoretically taken as the standard. Currents of lesser magnitude deposit equally good clots, but necessarily require longer time to produce a given result. It is advisable to introduce two or more needles, and to connect them alternately with the anode. With gilt needles, this alternation gives time for absorption of the nascent oxygen by the circulation; if ungilt steel needles be used, the polarisation is allowed to subside, and this otherwise seriously interferes with the action of the battery.

The insulation of the needles, so far as the portion outside the aneurism is concerned, should be as perfect as possible, not only to avoid the action of the current on the extra-aneurismal structures, but also to concentrate the current on the portion of the needle within the sac.

The propriety of introducing the cathode within the aneurismal sac, or of completing the circuit by a moistened electrode applied externally, resolves itself entirely into a question of resistance; for the deposition round the cathodal needle cannot be regarded as a clot, or as in any way aiding in the consolidation of the aneurism. If a sufficient current-strength can be obtained by the use of an external cathode, it is of no advantage to introduce it within the sac. At the same time, there is no objection to the use of an internal cathode, provided the shaft is well insulated; for it must be remembered that the caustic action of the current is chiefly confined to the cathode. The hydrogen liberated by an internal cathode has been proved by experience to be productive of no evil results.

The duration of an application must depend upon the current-strength, half an hour to an hour being usually sufficient. When not contra-indicated, it is well to allow the anodal needles to remain *in situ* half an hour after detachment of the battery, in order to permit of consolidation of the clots. The needles, especially those connected with the anode, should have a rotary motion imparted to them previously to withdrawal, in order as far as possible to avoid disturbance of the clots.

My investigations upon this subject not yet being complete, I hope on a future occasion to make known the results of further experiments.

## A CASE OF ABDOMINAL ANEURISM BECOMING DIFFUSED AFTER DISTAL COMPRESSION.\*

By E. MARKHAM SKERRITT, B.A., M.D. Lond., M.R.C.P.

Fellow of University College, London; Lecturer on Medicine and on Pathological Anatomy at the Bristol Medical School; Physician to the Bristol General Hospital.

THE patient from whom the specimens before you were obtained was a married man, aged 31, admitted into the Bristol General Hospital on November 2nd of last year. He was a clerk, a native of Bristol; had never indulged in any kind of violent exertion; never had gonorrhœa; careful inquiry elicited no suspicion of syphilis. Four years ago, he was ill for six weeks with rheumatic fever; he had suffered from no dyspnoea until lately. The present illness began about seven months before admission, with pain over the liver and tenderness on pressure. Soon afterwards, the patient had pain about the epigastrium, and a stoppage of the bowels for seven days occurred, which yielded to purgatives; the pain was then relieved. Similar pain then began to come occasionally on each side, about the umbilicus, or in the back, gnawing in character; two or three times, there were shooting pains down the right thigh. For the last fortnight especially, the epigastric pain had been worse after food, coming on almost directly after a meal.

\* Read before the Bristol Medico-Chirurgical Society.

and sometimes lasting for hours, slightly relieved by pressure. He had no nausea nor vomiting; his bowels were sometimes constipated, sometimes loose. The patient said he had lost two stone and a half in weight since his illness began. His breath had become rather short on exertion.

On admission, his abdomen was flat; the muscles were tense; pulsation was visible at the epigastrium. The aorta could be felt beating somewhat forcibly from the tip of the ensiform cartilage as far as the bifurcation, but most distinctly two inches below the tip of the cartilage; here there was a little tenderness on deep pressure. No abnormal lateral expansion could be defined. At the tender spot just mentioned, there was a slight prominence for about an inch from above down, where apparently some solid body about half an inch thick lay on the aorta; this body slipped up when the fingers were brought down. A *bruit* was heard along the aorta from half an inch below the ensiform cartilage down to four inches from the tip, most marked two inches and a half from the tip, where it was rough and rasping; much intensified by the least pressure; inaudible in the back. The iliac arteries pulsated in a similar way to the aorta, and a *bruit* was produced in them by very light pressure. The heart's impulse was weak; the sounds normal.

As the history of this case extends over nearly three months, I will merely give an outline of its more important features.

A fortnight after admission, the pain had become much more severe—occurring in violent paroxysms—chiefly in the right hip and thigh and right loin, lasting for a few minutes or for several hours. A thrill could now be felt in the epigastrium, two inches below the ensiform cartilage, where some expansive enlargement of the aorta could be detected. The *bruit* was much more distinct, and could be faintly heard in the back, opposite the first lumbar vertebra.

During the next month, there is little to note except the increased frequency and violence of the pain, which was rapidly wearing the patient out. At the same time, the tumour had become larger and more distinct, and the thrill was well marked. As the aneurism was making rapid progress, I resolved to try to cause coagulation in the sac by compressing the aorta *below* the aneurism, the situation of which made proximal pressure impossible. At the same time, I fully recognised that the prospect of success was not great, and that there would be considerable risk owing to the increased pressure that would be produced in the sac. Accordingly, on December 12th, I had the benefit of a consultation with my colleagues, who agreed that the method of treatment I proposed was the only one that would give the patient a chance of life, small though that might be.

Next day, December 13th, the bowels having been freely opened, the patient was put under the influence of ether, and at 10.50 A.M., Lister's abdominal tourniquet was adjusted, and the pad was slowly screwed down till pulsation ceased in the femorals, the middle of the pad being about an inch and a quarter above the umbilicus and two inches below the lowest part of the tumour that could be felt. The pulsation in the aneurism at once became much more forcible, and I slackened the tourniquet till the pulse could be felt in the femorals. Pulse 104, regular. In ten minutes, the pad was again down so as to stop pulsation in the femorals. At 11.26, the pulse was 108, weak and small; the tumour was rather less distinct, and no thrill could be felt, but the *bruit* was unchanged. At 11.40, a distinct thrill was again felt. At 12.40, no thrill was to be detected. At 1.10, there was a slight intermittent thrill, and the pulsation of the tumour was decidedly less marked. At 2.30, the general condition seemed as before; but on putting the hand on the lower part of the thorax on the right side, there was to be felt distinct pulsation, forcibly expansive, extending from the tenth right interspace to two inches above the iliac crest, backwards to the edge of the quadratus, and outwards as far as the posterior axillary line, corresponding to a distinct rounded bulging of the surface. The tourniquet was removed, and pulsation in the femorals was at once fully restored. The patient had been kept quietly under ether for four hours, without any difficulty; and there were no signs of disturbance from the compression, except that the urine passed soon after contained a trace of albumen.

Next day, the epigastric pulsation was less distinct, but wider; the tumour in the right loin was beating forcibly, over a rather larger area, and a faint *bruit* was heard over it, apparently conducted from the aorta.

During the next three weeks, the pain became frequent and most intense, so that the patient took daily about ten grains of morphia hypodermically. By the end of this time, the local condition was as follows. On the right side posteriorly, there was an egg-shaped pulsating swelling between the ribs and the iliac crest, about three inches long by two wide, visible on the surface, tender. On the left side, in a similar position, a pulsating tumour was now felt, bounded

above by the line of the last rib, below by the iliac crest, and reaching outwards for three inches from the spine; tender at its outer part. A *bruit* was heard over the tumour on both sides. If the hands were placed, one on each side of the body, over these prominences, they were distinctly separated at each beat of the heart.

From this time, the patient gradually sank; the pain continued; emaciation became extreme; slight oedema appeared over the swelling on the right side; and he died on January 29th, nearly seven weeks after the compression of the aorta and the diffusion of the aneurism.

**POST MORTEM EXAMINATION.**—On opening the abdomen, the peritoneum was found to be pushed over to the left as far as a line one inch inside the anterior superior iliac spine by a tumour lying behind it; and the viscera were consequently displaced to the left. On removing the stomach and intestines, the aneurism was exposed. It lay behind the whole abdominal cavity and beneath the psoas and iliacus muscles. It might be described as composed of two large, thick, conical masses, with their bases upwards, united at their sides for two-thirds of their length, while their free ends passed downwards to each thigh along the brim of the pelvis. The right mass was the larger, being about four or five inches thick, and reaching up to the liver; its right border was uncovered by peritoneum, and filled the whole space between the abdominal wall in front and the abdominal wall behind. The tumour consisted of a large quantity of soft dark clot and dark fluid blood shut in simply by the muscular layers of the abdominal walls strengthened by fibrin deposited amongst them. The posterior wall of the aneurism was formed of the eroded spine in the middle line, and at the sides the muscles and other tissues bounding the body behind. On the left side, a conical cavity full of clot passed down beneath Poupart's ligament along the psoas into Scarpa's triangle, and then downwards and backwards for three inches towards the perineum. The aneurism had sprung from the back of the aorta just below the diaphragm; its mouth was a smooth rounded opening three-quarters of an inch across. The limits of the primary sac could not be made out. The spine was deeply eroded at the last dorsal and first two lumbar vertebrae. The aorta was atheromatous, the arch slightly dilated. The heart was healthy.

**REMARKS.**—There are four chief ways in which aneurism of the abdominal aorta may be treated: by rest and diet simply; by drugs; by galvano-puncture; and by mechanically more or less preventing the flow of blood through the sac. It was not found practicable to diet my patient strictly; he always felt much worse when taking iodide of potassium; galvano-puncture was not admissible, as the aneurism had nowhere shown signs of approaching the surface; as, therefore, the patient was growing rapidly worse, there remained no choice, but either to let him die or to try the effect of compressing the aorta beyond the aneurism. The distal treatment of aneurism that we are most familiar with is that where a permanent ligature is put round a vessel or vessels beyond the sac; this, as is well known, has been done for aneurism at the root of the neck, when the carotid has been tied for aneurism arising close to its origin; or where the carotid, subclavian, or both vessels, have been ligatured for aneurism of the aorta or the innominate. But if proximal compression has been substituted to a great extent for the old Hunterian operation, there is no apparent reason why compression beyond the aneurism should not be used in suitable cases instead of ligature. Where the aneurism is high up on the abdominal aorta, we are limited to temporary compression of the vessel below, with the object of producing rapid coagulation in the tumour.

What chance of success has this distal compression of the abdominal aorta? One of the earliest cases in which this method was tried was Bryant's, when Lister's abdominal tourniquet was applied for twelve hours, removed for twelve hours, and again applied for four; at the end of that time, alarming symptoms set in, and the patient died in eleven hours. *Post mortem*, it was found that the intestine had been bruised by the pad, and had set up fatal peritonitis; but that the aneurism, involving the coeliac axis and the superior mesenteric, was consolidated. In the few other cases on record, no such result followed; but this one instance is enough to justify the proceeding, and to allow hopes of success, although, theoretically, the chance of consolidation is small; because in such a case, the great probability is that free circulation will be kept up in the aneurism owing to the origin of large vessels either from the sac itself or between it and the point of compression.

What are the dangers of distal compression? The only one not shared by the proximal operation is the risk of rupture of the aneurism, owing to the increased pressure on its inner surface caused by the arrest of the flow through the aorta beyond. This accident happened in the case I have related; and another instance is recorded in the BRITISH MEDICAL JOURNAL of April 21st, 1877, where the abdominal aorta

was being compressed by Heath of Manchester for aneurism of the common femoral, when death resulted from rupture of an unrecognised abdominal aneurism above the point of compression. In my case, the rupture took place into the retroperitoneal tissue; and, therefore, death did not at once result, but a false aneurism was formed, which attained an enormous size. It is worthy of note, however, that in cases of distal ligation at the root of the neck, there has often not been increased pulsation in the sac, but, on the contrary, a speedy diminution in both the impulse and the size of the aneurism. Thus, while fully recognising the risks accompanying distal compression of the aorta, we are justified in adopting this treatment with some hope of success; and more especially because we have to do with a disease that is almost invariably fatal—it may be very speedily—if left to itself. I do not consider that my patient's life was materially shortened by the result of the treatment, seeing that he lived seven weeks after it, and that, when it was adopted, the aneurism was making rapid progress and the patient was apparently fast dying from exhaustion.

## A CASE OF DIVIDED UTERUS AND VAGINA.\*

By JAMES MURPHY, B.A., M.D.,

Lecturer on Botany at the University of Durham College of Medicine,  
Newcastle-upon-Tyne.

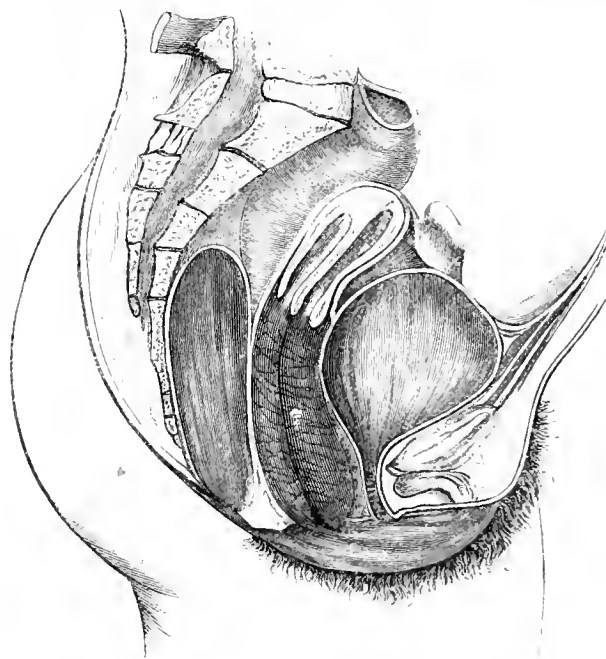

As cases of divided uterus and vagina (a condition normal in the marsupialia) are not very common, and as they possess a certain amount of interest from an embryological point of view, I am anxious to place on record a case that has recently been under my care, in which both these conditions were very well marked.

But, first, I may say a few words on the etiology of this malformation. The whole female genital canal, from the vulva to the fimbriated extremities of the Fallopian tubes, is formed out of two (originally separate) tubes, called, from their discoverer, "Müller's ducts". Now, while the upper portions of these ducts, which go to form the Fallopian tubes, remain separate, under ordinary circumstances the lower portions, which go to form the uterus and vagina, become as it were fused together at the eighth week of embryonic life; and it is when they fail to coalesce that we have developed those conditions which are known as uterus septus and vagina septa.

Mrs. T., aged 32, married for seven years, never pregnant, consulted me a little time ago about a cyst in her right labium; and, on examination, I also found the following conditions present. A septum, springing from each labium minor, a little anterior to the fourchette, extended to the uterus, completely dividing the vagina into two portions: an anterior and larger canal and a posterior and smaller one. This septum, which was at its commencement about a tenth of an inch in thickness, but gradually became thinner as it approached the womb, was composed of a strong dense tissue covered with squamous epithelium, composed of those large cells peculiar to the vagina, with the mucous membrane of which it was continuous. The anterior canal was slightly smaller than a normal vagina, and the posterior one something smaller than its fellow, but the two combined were not much larger than an ordinary vagina; for, when one canal was dilated it encroached on the other, as the septum could be stretched to a considerable extent. The vulva was normal, and the carunculae myrtiformes were well developed round the commencement of each vagina, so that it is probable a double hymen existed. In the anterior canal was a cervix, quite normal as to situation and form, but the size a little less than usual. Through the os a sound could be passed to the extent of about two inches, but there was a slight amount of stenosis present. In the posterior canal, a small short cervix could be felt, crowded up to the anterior superior corner of the canal, and through the os a small sound could with difficulty be passed for about an inch and a half. To determine if the uterus were divided, I passed a sound through each os, and endeavoured to touch one sound with the other; and as I failed to do this, after several patient and careful trials, I think I may fairly assume that the septum exists in the uterus also. By placing two fingers in the anterior canal against the anterior portion of the womb, and pressing the fingers of the other hand on the abdomen, well down behind the uterus—i. e., by the conjoined method of examination—I could make out the fundus, which appeared quite normal, and, as well as I could determine, there was but one ovary on each side, as would be expected. By changing the hand on the abdomen to the anterior surface of the uterus, and introducing a finger into the posterior canal, the double cervix seemed once and a half as large as usual. Being anxious to determine whether she menstruated from both wombs, I requested her to come back during

a monthly period; and, on examination with a speculum, I found the catamenial fluid flowing copiously from the anterior os, and very slowly, but still distinctly, from the posterior one.

The patient was not aware of anything being amiss, except the cyst, and that she had suffered from dysmenorrhœa for the last year, which

was owing to the stenosis existing in each os. I purposely dilated the anterior one first, without interfering with the other, when the dysmenorrhœa was much relieved, but still existed to a slight degree. I then dilated the second os; and she has been quite free from pain during the four periods that have since elapsed.

The accompanying drawing, which is fairly accurate, will convey a better idea of the case than I have been able to do by words.

## BATH THERMAL MINERAL WATERS: THEIR USES AND ABUSES.

By A. B. BRABAZON, M.D.,

Physician to the Bath Mineral Water Hospital.

### III.

*Diseases of Skin.*—The types of cutaneous affections which commonly are presented for treatment in the Bath Mineral Water Hospital belong to the pustular, papular, vesicular, and squamous classes. I have also seen one or two examples of the class bullæ. Under the head of pustular, I find acne, impetigo, or impetiginous forms of eruption, affecting various parts of the body. Of the vesicular class, eczema contributes the most numerous examples; of the squamous class, lepra and psoriasis are most abundant; lichen generally represents the papular form; and the class bullæ is occasionally represented by cases of pemphigus, though the occurrence is unfrequent.

I regret that a large number of cases are discharged under the simple head of "Skin-disease", but as to more determinate classification are "anonymous". I think I may confidently say that these cases may be considered as coming collectively under the classes above named, although I am unable to place them in a more decided classification. Of pemphigus, I have had under my own care two most decided cases, in both of which, rather contrary to my expectation, the eruption rapidly disappeared under treatment. Of the pustular class, I find cases of acne discharged cured, but whether acne simplex or acne indurata is not mentioned. I should, from the pathology of the disease, expect such a result. I find also cases of impetigo, or impetiginous eruptions, discharged cured or much better; and my personal experience

\* Read before the Northumberland and Durham Medical Society.

fully corroborates the truth of these recorded results in this treatment of such diseases. With regard to eczema, the number of cases discharged is, I think, sufficient whereon to form practical conclusions; in fact, my personal experience fully corroborates the facts, and I think my testimony may be accepted as unprejudiced, when I state that my anticipations led me to expect a totally different result. I hardly expected that any case of eczema would be benefited by a course of treatment apparently so opposed to that approved of by Mr. Erasmus Wilson, whose advice I have frequently followed with success. I am happy to say that there is nothing in the present instance to cause me to underrate that advice or to alter my usual treatment.

I have had under my own care in the hospital some most troublesome cases of this most troublesome disease; and I have found these cases most decidedly improved by: 1. the internal administration of the waters; 2. deferring their external application until the more acute local symptoms had entirely subsided; 3. following out Mr. Wilson's expressed advice, viz., to keep the surface as dry as possible and unwashed. I have found the constant application of a powder composed of equal parts of finely powdered oxide of zinc and starch most useful in protecting the skin.

I find that twenty-one cases marked "eczema", consisting of twelve males and nine females, were discharged during the year ending May 1877. Taking the males first, five were discharged under twenty, of which number two were "cured" and three "much better"; giving a percentage of 40 per cent. "cured" and 60 per cent. "much better". As only one female was discharged under twenty, we will pass on to the double decade between twenty and forty. Two females were admitted at this period of life, both cured. Between forty and sixty, on the male side, three out of four were discharged "much better", equivalent to a percentage of 75. On the female side, at the same age, one out of four was discharged "much better", being equivalent to 25 per cent. Passing by the term "better" as of equivocal value, let us inspect the quantities under the more important term, "no better". Among males, there was only one discharged under this head, aged between forty and sixty; being one out of four admitted at the same age, equivalent to 25 per cent. "no better", against 75 per cent. "much better". Females appear less fortunate, as at ages between forty and sixty two out of four were discharged "no better", equivalent to 50 per cent. In other words, the chances of improvement in males compared with females, both being aged between forty and sixty, are as two to one in favour of males. Looking to the sum total of results and finding the proportions, males and females, taken collectively, to be 12.5 per cent. discharged "cured", against 4.2 per cent. discharged "no better", I think I am entitled to the verdict of an impartial jury in favour of the proper use in eczema of the Bath Mineral Waters, for which I can assure my readers I am no special pleader.

Under what I have termed "anonymous" skin-diseases, thirty-five were discharged, twenty-one males and fourteen females. As I have already said, these were most probably, indeed I might say almost certainly, composed of those forms of cutaneous disease, which I have mentioned as usually submitted to treatment in this hospital. I believe we may take the numbers relatively to accord with the numbers admitted of the subjoined classes of disease.

*Lepra*.—Males, 1; females, 4; total, 5.

*Psoriasis*.—Males, 2; females, 5; total, 7.

*Eczema*.—Males, 12; females, 9; total, 21.

*Diseases not named*.—Males, 21; females, 14; total, 35.

All diseases of skin included make a total of 68; to which lepra contributed 7.3 per cent.; psoriasis, 10.2 per cent.; eczema, 30.8 per cent.

I need not occupy the time of my readers unnecessarily by entering into details of this unclassified group of skin-diseases. I shall only point out, for their consideration, the percentage of cured and no better, and leave it to them to draw their own conclusions. Percentage of cured, total of both sexes, 48.5; no better, 0.

As to the benefit derived in cases of lepra and psoriasis, even when of an aggravated form, there is no possible doubt, at least in my mind.\*

*Diseases of Specific Origin*.—I have now arrived at the consideration of the diseases which I have termed as arising from specific causes, such as poisoning from lead, mercury, arsenic, etc. We may also, for the sake of convenience, include cases of syphilitic poisoning. Cases of lead-poisoning, in point of number, stand by far first on the list; in fact, as a rule, the hospital is seldom without several specimens presenting different forms and complications. Thus we find paralytic or semiparalytic conditions, varying from comparative to complete loss of

muscular power, as in wrist-drop, when, in some instances, the patient has not power to hold a pen.\* We also find, occasionally, lead-colic. As to complications, we find lead-poisoning very frequently associated with gout and rheumatism; so frequently, that I am disposed to think that it may sometimes act as the specific cause. The well known condition of gums, diagnostic of lead-poison, is rarely absent. I have even found it where no special symptoms had presented themselves, and where the patient had been admitted as suffering from gouty or rheumatic pains in the joints or limbs. It is occasionally very difficult to arrive at the source from which the poison was procured; nor is it to be supposed that the effects of the poison are confined to painters, or those whose daily occupation brings them into absolute contact with the metal; we frequently find them in agricultural labourers, who can give no clue to the real history of the case. I presume that in such cases the metal is introduced into the system in the way of food or drink. During two years, ending May 1877, forty cases of lead-poisoning were treated in and discharged from the hospital: thirty-seven males and three females. There were no cases under twenty. The largest number discharged was between the ages of forty and sixty, being males; and the averages per cent. in proportion to numbers discharged, at this age, were 10.8 "cured" and 75.6 "much better". There were none discharged "no better". The total average per cent. of cured males and females collectively, is 12.5. As might be expected, the number of females treated in the hospital for lead-poisoning is too small to attract any special attention or to form a basis for any definite conclusions.

Cases of mercurial or arsenical poisoning are rarely admitted. I can find but one mentioned of mercurial (quicksilver) poisoning, and this patient was speedily discharged, having shown symptoms of suicidal mania. In speaking of arsenical poisoning, I only allude to arsenical poisoning from wall-paper, of which, during the year, there has been no case recorded.

I shall conclude with a few observations on syphilitic cases. Cases of syphilis, *per se*, are not usually admissible to the hospital, but we find many cases in which, to say the least, a strong suspicion of syphilis underlies the apparent symptoms, which are usually of the rheumatic type. Patients are very reticent indeed on the subject; and it is only by careful examination and cross-questioning of the patient, that one can arrive at the truth. The cases of this kind which have come under my notice, have certainly derived benefit from mineral water treatment. In private practice, I have met with two or three cases of aggravated tertiary symptoms, such as nodes, diseased bone, rupia, emaciation, nocturnal pains, etc. As a rule, in these cases, the warm baths were most efficacious, particularly in relieving the nocturnal pains; but great care is necessary in their administration, as, if taken too frequently or at too high temperature, they will certainly increase the severity of the hectic fever usually present in such cases, and cause greater emaciation and consequent debility.

I have now finished the task which I set before me, viz., that of attempting to establish, by statistics, some rule for guidance in selecting or advising patients as to the propriety of submitting themselves to treatment by the Bath Mineral Waters. I hope I have so far fulfilled my mission as to place before my readers these statistics in such a form that, given disease, with age and sex, a glance at the table annexed (Table I) may enable them to arrive at a fair conclusion as to the possibilities or probabilities of relief or permanent improvement on the one hand, or as to the inutilty and waste of time in seeking cure or relief under the circumstances, which rendered the realisation of such an expectation improbable, if not impossible.

As regards the *modus operandi* of the Bath Mineral Waters, I wish I could throw any scientific light on the subject, but at present, at least, I have not the data sufficient to work on. These necessary data will require very close observation, and, above all, careful quantitative analysis of the urine. I hope at some future time I may be able to add my mite of information on the subject. There can be no doubt that the therapeutic action of the waters, used internally, is largely due to the action on the kidneys and renal secretion, and also on the gastrointestinal mucous membrane; in other words, the action is one of elimination through these channels; and in addition to these effects are to be considered the antacid or tonic effects of alkaline-chalybeate waters. The effect of the baths, or external application of the waters, is also that of elimination by the skin, as well as producing softening and absorption of effused material when it can be absorbed. There is one peculiar effect of these waters when first used, and not wholly an agreeable one to the patient, namely, an aggravation of the local symptoms, increased pain, and often increased swelling in cases of gout or rheumatism. This fact would appear to favour the theory of

\* Since writing the above, I have had admitted under my care a case of congenital "ichthyosis". Three other members of the family are similarly afflicted.

\* Since writing the above, I have had admitted under my care a well marked case of paralysis of the extensor brevis digitorum pedis from lead-poisoning.

Temperature.—King's Bath, 117 deg. Fahrenheit; Hot Bath, 120 deg. Fahrenheit; Cross Bath, 104 deg. Fahrenheit. The nitrogen daily evolved from the springs amounts to about 250 cubic feet.

Dr. Bence Jones as to the cause of this pain and swelling, which he attributes to increased oxidation, and which he looks upon as a natural therapeutic effort to eliminate the effects of suboxidation. Undoubtedly, most of the cases in which the symptoms are at first somewhat aggravated are in the end those in which the waters will be found most efficacious.

Mr. Coppinger, the resident medical officer to the Mineral Water Hospital, has kindly made some investigations as to the effect produced on the chemical reaction and quantity of the urine by the in-

ternal use of the waters. He has tabulated these conditions as found existing on the patient's admission into the hospital; also at intervals during their sojourn there. I need not explain the difficulties in the way of pursuing such investigations in the hospital; but I have every reason to trust to Mr. Coppinger's diligence and watchfulness in conducting these observations. I append twelve cases in the form in which he has reported them, in order that my readers may try to deduce some practical inferences as to the effects of the mineral waters as regards the renal secretion (Table II). For purposes of general in-

formation, I will also append the latest analysis of the Bath Mineral Waters by Captain Heriot, Royal Marines. (Table III.)

In concluding the foregoing remarks and observations, I may be pardoned if I repeat that which I have already wished to convey to my readers, namely, that it is with no intention of dictating to them, least of all with any assumption of superior knowledge. I have ventured to say that which many others would have said much better had they the same opportunity or desire to do so, but "*Non cuius homini contingit adire Corinthum*", which in the present instance, if freely translated, means, "It is not every professional brother who visits Bath"; though I trust that by the end of this year the number of non-visitants in the profession will be but very small indeed.

To those of my readers who are already well acquainted with the uses as well as the abuses of the Bath Mineral Waters, I will address the following quotation, with which I will now conclude.

"*Si quid novisti rectius istis,  
Candidus imperti; si non, his utere mecum.*"—*Horatii Epistol. v, Liber i.*

## SURGICAL MEMORANDA.

### CATGUT LIGATURE.

ON November 17th of last year, I tied the hind part of the right subclavian artery in the Manchester Royal Infirmary with a catgut ligature. The patient died of cardiac disease on the eighth day following; and, on examination, it was found that the ligature had, with the exception of a short interval of about one line in length, completely cut its way through all the coats of the vessel. There was no occlusion whatever of the artery, nor even any coagulum; so that doubtless the hæmorrhage would have been fierce and uncontrollable had the man survived longer. I make a note of this, because I think it goes far towards establishing the correctness of the opinion that catgut is an unfit agent for securing arteries in their continuity. It is true that catgut is efficient and safe in deligating the vessels severed in amputations; and I think, for the reason that, the limb being removed, less blood is sent down the divided arteries, and so but little stress comes upon the encircling ligature (it is otherwise when a ligature is applied for the cure of aneurism); and, as a consequence of this, it yields, and so, permitting the re-establishment of the stream, prevents the formation of a coagulum. S. MESSENGER BRADLEY, Manchester.

### CATGUT DRAINAGE.

I BEG to thank Mr. Messenger Bradley for his prompt reply to my request for his reasons why Chiene's method of catgut drainage is "most inefficient". He gives these reasons under three heads.

1. *Catgut drainage is inefficient, because it does not act by capillarity.* This is no argument for or against its efficiency or inefficiency. My explanation of the mode of action of a skein of gut may or may not be true. That question is altogether apart from the question at issue. I therefore do not enter upon it.

2. *Catgut is inefficient, because, as Mr. Bradley has seen it applied, it only drains the superficial parts of a wound.* In my original paper (*Edin. Med. Journal*, September 1876), it is distinctly stated that the drain is to be stitched to the bottom of the wound. A surface-drain in a wet meadow will only remove surface-water; a hank of gut placed superficially in a wound cannot be expected to drain away the discharge from the deeper parts of the wound.

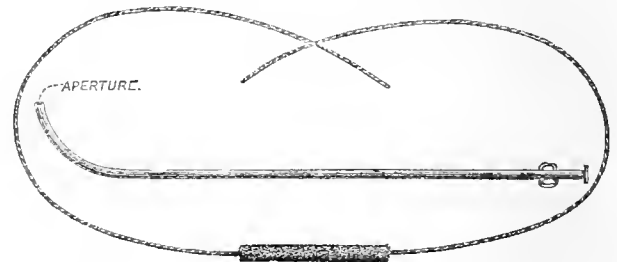

3. *Catgut is inefficient, because it does not last long enough.* A skein of the finest gut of four threads is absorbed, as a rule, within a week; a skein of twelve threads, in from ten to twelve days. In this time, the wound, if it is to heal by first intention, will be beyond the necessity of drainage. It is stated in the original paper that I do not allude to the use of catgut in suppurating wounds. I feared that catgut would not remove pus. Further experience has shown this to be true. When suppuration occurs, a drainage-tube must be inserted. As long as suppuration is the exception, not the rule, we are justified in using catgut in those cases in which our aim is union by the first intention. This is one of the advantages claimed for the catgut over the drainage-tube.

I trust that I have answered Mr. Bradley's objections. Mr. Bradley should have read with care the original paper, and should have tried the method of application there recommended, before making such a sweeping accusation. Until he has tried it in the way recommended by me, he has no right to say, and he cannot expect me to accept his assertion, that "Chiene's method of catgut drainage is most inefficient". Perhaps I may be allowed to add that I have used catgut

as a drain in every available case in hospital and private practice since September 1876, and that I still feel justified in recommending it to the notice of the profession. JOHN CHIENE, Edinburgh.

### NEW METHOD OF CLEANING CATHETERS.

I HAVE always thought that the thorough cleaning of catheters by washing them out and blowing through them is impossible and distasteful. The oil-stain is persistent, and the cone at the tip of the instrument is a nidus for successive deposits of impurity; and I protest personally against soiling my lips with a machine that, a few minutes previously, was an urine-duct. To remedy these inconveniences, I have been accustomed to use catheters with through communication and a bristle brush with double handle. Catheters pervious from tip to handle are more easy to introduce, and give less pain on withdrawal than eye-sided instruments, because they are smoother, and the spasm of urethral muscles has no grip on the side excavation. If the catheter be not introduced too far, the bladder-wall cannot occlude the hole at the tip. The bristle brush is shown in the diagram; it can

easily thread the catheter, and may be passed to and fro as often as desired in a weak solution of soda and water.

Breech-loading barrels, from a pure point of view, are preferable to the old muzzle-loading; and, as a sportsman considers his barrels foul if only soaked in warm water and blown through, so also should a surgeon condemn his catheter as unclean if only treated in a similar way. The catheters and brush are manufactured by Messrs. Wright and Co., 108, New Bond Street, W.

RICHARD DAVY, M.B., F.R.C.S., Surgeon to the Westminster Hospital.

## THERAPEUTIC MEMORANDA.

### TURPENTINE IN ENTERIC FEVER.

I HAVE read with great interest the remarks in the *BRITISH MEDICAL JOURNAL* of December 15th, 1877, on the use of turpentine in enteric fever, by Mr. R. P. White; and I have employed it in the treatment of this disease with the most marked success. We are indebted to Surgeon-Major Moffitt, 15th Regiment, for having brought this mode of treatment under the notice of the profession in India; and I am informed by him that it was from his uncle, Dr. Moffitt of Sydney (who has been in the habit of using it for the last fifteen or twenty years), he first learnt its value in these cases. About two years ago, Surgeon-General Stewart called for reports on this mode of treatment, and I have no doubt they will be published in the next departmental blue-book. I was at that time quartered at a station (Ahmedabad) where, if a case of enteric fever did occur, it was almost always fatal; but after the adoption of the turpentine treatment I never lost a case. As to its *modus operandi* I can scarcely speak; but it appears to me, from what I have seen of it, as much a specific for enteric fever as is quinine for ague or ipecacuanha for dysentery. I may add that the mode of administration I have found most useful is, as recommended by Dr. Moffitt, half-drachm doses four times daily, made up with mucilage or yolk of egg.

E. J. McGRATH, Surgeon-Major Royal Artillery.

### RHAMNUS FRANGULA.

As the profession appears returning to the use of the "rhamnus frangula or black alder", the following account of it may interest the readers of the *JOURNAL*.

Dr. Quincy, in the twelfth edition of his work entitled *Pharmacopœia Officialis et Extemporanea, or a Complete English Dispensatory*, printed in the year 1742, under section Cathartics, remarks:—"Ainus nigra,

the black alder, called also *frangula*: the *arbor fetida*, or stinking tree, of some writers, is the same; and the *alnus nigra baccifera*, the black-berry-bearing alder of *C. Bauhine*, is the sort referred to by our official prescriptions, though, indeed, it is but seldom met with in them. It is a very strong cathartic, and used, therefore, to be given in dropsies and where a great load of humours is to be purged away. The ancients accustomed themselves to correct it with cinnamon, ginger, and the carminative seeds; but it is now very little in use."

LUCIUS HOLLAND, M.D.

## A READY MODE OF CARRYING AND ADMINISTERING CROTON-OIL.

WHEN croton-oil is required for internal use, the case is an urgent one, usually either apoplexy or cerebral hæmorrhage, and time is all-important. It has heretofore been prescribed in powdered sugar, or is carried made into small pills. The latter have various disadvantages; they dry and become hard, or, from our patient's unconscious state, cannot be swallowed. When formerly engaged in country practice, I had several times occasion to wish that some portable and efficient mode of carrying the pure oil were devised, and at length hit upon a plan which seems adapted for other medicines besides croton-oil. This consists in making use of the little lead tubes which are employed for artists' oil-colours. There was some difficulty in obtaining them small enough; but Mr. Mackay, of Messrs. Duncan, Flockhart and Co., took the matter up and worked it out for me. Each tube contains ten or twelve drops of oil, kept secure by a little lead cap fitted with a cock, which screws on. On removing the cap, a very small aperture is exposed, from which a drop of any size can be squeezed either on to a small piece of sugar or on to the handle of a spoon, and thence conveyed to the back of the patient's tongue. The tube fits into one of the divisions of the pocket pill-case made of tin sold by Duncan and Flockhart, and thus is always at hand and ready for use.

It appears to me that the same mode might be applied to the preservation of a sufficient quantity of nitrite of amyl for use in cases of emergency, a tube containing a slightly large quantity being employed.

W. ALLAN JAMIESON, M.D., F.R.C.P., Lecturer on Diseases of the Skin, Edinburgh School of Medicine.

## TWO CASES OF INFANTILE OPIUM-POISONING TREATED WITH ATROPINE.

CASE I. September 29th, 1875.—The infant boy, fourteen days old, of Mr. A., having had looseness of the bowels for some days, got what was said to be half a drop of laudanum: I have, however, reason to believe it was more. The dose was administered about 10 A.M. At 2 P.M., the child was in a deeply somnolent condition; brisk rubbing and slapping made it cry, although its eyelids remained closely shut; it occasionally moaned and breathed deeply, but mostly lay limp and passive; the lips were livid; the pupils of the eyes strongly contracted; the face was pinched and drawn; the cheeks were bloodless, and round the eyelids there was a dusky hue. The ordinary methods of treatment were tried, with varying success, till 8.30 P.M., when I commenced to moisten his lips with solution of atropine (four grains to the fluid ounce), and to keep them moist. By this time, the pulse at the wrist was imperceptible, and there was only a thrill over the region of the heart. At 9.30 P.M., there was a distinct change on the pupil; it was dilating; the breathing shortly became hurried and gasping; the pulse appeared at the wrist; the cold skin became hot and fiery. At 10 P.M., there was twitching of the fingers and hands and muscles of the face, and general slight convulsions, especially on touching the head or feet. From this time, there was a great variety of struggles: evidently the results of the administration of the atropine as well as of the opium. Injections of warm water were frequently given, and a little milk with a few drops of whiskey. At 8 A.M. on October 1st, the breathing was still oppressed; the eyes were clear; the pupils movable but sluggish. He had passed a fair night, and had motion from his bowels; the scrotum was œdematous. At 1 P.M., the effects of both opium and atropine seemed to have passed away; there was slight dullness on percussion on the left lung, in the region of the nipple; the belly was hard and tympanitic. On October 2nd, matters were improved, and from this time all went well.

CASE II.—An infant girl nine days old, on November 23rd, 1877, at 5.40 A.M., got at least four drops of liquor opii sedativus (Battley's) to quiet its crying. In about ten minutes, it fell into a deep sleep; began to look livid in the face and to breathe gaspingly. Between 6 and 7.30 A.M., she had several general convulsions, which nearly carried her off. At 7.45 A.M., the lips were moistened with solution of

atropine (one grain to the fluid ounce). As often as the lips dried, they were moistened again. There was one severe convulsion only after beginning the treatment and several other mitigated ones. At 8.40 A.M., the general appearance of the child was very bad; she had livid ring-like marks round the mouth and brow; the brow was wrinkled and contracted; the mouth partially open and slightly paralysed; the tongue thick, white, and furred; the lips dark, hard, and dry; the skin hot and dry; the pupils extremely contracted and quite immovable; the eyeballs varying every moment, with converging and diverging squint; the breathing occasionally totally suspended and then resumed with a gasp. She had not been at the breast since one this morning. At 11 A.M., the breathing was still more disturbed; the pupils only about the size of a pin-point; the squinting frightful; pulse almost imperceptible; the brow contracted in crescents; the body felt warm. At 1 P.M., she died without further change.

REMARKS.—In the first case, I have no doubt the child got rather more than enough atropine; in the second case, rather less. The first recovered and the second died. I am convinced the quantity of opium given in both cases was very similar; but, in the latter case, I believe the quick superintention of the convulsions would have rendered any amount of antidote useless, as the vital energy was already pretty nearly exhausted.

J. STUART NAIRNE, Surgeon, Glasgow.

## ON THYMOL AND ITS ALLIES.

As the therapeutic uses of thymol are at present exciting some attention, especially in regard to its application for surgical purposes, it may not be out of place to point out that cymene, the essential basis of this body, exists in various other organic products, from one of which it may be obtained much more cheaply than it can be from thymol. The most available source of cymene is terebene, a body which I introduced to the notice of the profession, a few years ago, as an efficient disinfecting agent, and which is now largely used for surgical purposes. Cymene may be obtained from terebene in an approximately pure condition by fractional distillation, or in a still purer state by other processes. Another source of cymene is cymol, the terpene of oil of cammin, as thymol is of oil of thyme. If alcoholic solutions of rectified terebene, cymol, and thymol are compared with one another, they will be found so nearly identical as to be with difficulty distinguishable. It is the presence of cymene in terebene which probably explains, not only its powerful disinfectant action, but also its antiseptic and healing influence on suppurating wounds.

FRANCIS T. BOND, M.D., Gloucester.

## OBSTETRIC MEMORANDA.

### TURPENTINE IN POST PARTUM HÆMORRHAGE.

I AM glad that it is in my power to give Mr. Pollard the results of some cases of *ante* and *post partum* hæmorrhage which I have treated with the oil of turpentine, a plan of treatment the efficacy of which I have proved, the drug having been given in sufficiently large doses. Fashion in medicine has caused many to cease the prescribing of turpentine: a fact manifest by its entire absence as an internal agent from nearly all of our modern obstetrical text-books. Should its use be revived, I am convinced that it would be of great value as a hæmostatic, and would do away with some of the strong objections to ergot.

CASE I.—Mrs. H., aged 33, a strong countrywoman, was in her seventh pregnancy, at the full period. On expulsion of the placenta, severe flooding ensued. Cold water injections, pressure, etc., had no effect. I gave a draught containing half an ounce of turpentine, and about three minutes afterwards felt the uterus contract. The hæmorrhage stopped.

CASE II.—Mrs. P., aged 22, a healthy town woman, was in her first pregnancy, at the seventh month. On being sent for suddenly, I found her pallid, almost pulseless, and losing a great quantity of blood. I gave half an ounce of turpentine beaten up with the yolk of an egg, and introduced ice into the vagina. The hæmorrhage stopped, and she came to her full time.

CASE III.—Mrs. T., aged 28, an anæmic-looking woman, was in the fifth month of her third pregnancy. She had fallen down three steps of stairs. Pains came on, with violent flooding. I gave half an ounce of turpentine in draught. A fetus was expelled: the hæmorrhage stopped.

CASE IV.—Mrs. K., aged 21, a half-starved-looking factory girl, was in the seventh month of her second pregnancy. Having been kicked by her husband, pains and flooding succeeded. I gave half an

ounce of turpentine with egg. The flooding was severe. I repeated turpentine in three hours. The hæmorrhage stopped. She had premature delivery.

Turpentine may be given in milk, whiskey, beaten up with the yolk of an egg, or, as I prefer most, in a draught composed as follows: R Olei terebinthinæ ʒss; liquoris potassæ ℥xxx; pulveris tragacanthæ q. s.; aquæ menthæ piperitæ ad ʒij. M. Fiat haustus. When given in this form, I have never found nau-œa produced.

WILLIAM CLIBBORN, M.B., Birmingham.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### DR. ANDREW'S WARDS.

*Diffused Thromboses.*—A stout heavily built man, thirty-three years of age, was admitted to the hospital after fourteen days' illness, suffering from painful swellings in various parts of his body. He had been previously healthy; there was no history of gout or of exposure to infection or any poisonous influence; there were no wounds, injuries, or other probable source of purulent infection. His illness began by the onset of pain in both feet, without rigors or any other symptom than pain; subsequently, painful swellings formed in the legs and thighs. There was no general œdema, and no definite sign of joint affection. The heart and other organs appeared normal, and the urine was healthy, with an abundant deposit of lithates. When seen, the principal swellings were situated in the thighs, the recti muscles of the abdomen, and on both sides of the neck. The left arm had been attacked while under observation; a swelling formed near the elbow, and spread upwards and downwards, with great pain; it is now subsiding; the skin over it appears wrinkled. In none of the swellings has there been any sign of suppuration; there has never been any sign of erysipelas, nor any reason to suspect pyæmia. During the three weeks of illness, several of the swellings have subsided, though some are still increasing. There is no sign of disease of the lymphatic glands.

Dr. Andrew considered the nature of the disease extremely doubtful. It could not be described by any general name. The swellings appeared to be due to numerous local thrombi, but the exact pathological cause of the thrombosis was not apparent. The temperature has never been above 100 deg. Fahr., and there has never been any vesication of the skin; but in the right axilla there has been some excoriation, owing to local friction of the surfaces. When the pain was severe, hypodermic injections of morphia were used. The patient has been placed on a generous diet, with lemons, and a mixture containing nitrate of potash and carbonate of ammonia has been given.

*Arterial Sclerosis.*—A cellarman, thirty-two years of age, was admitted as an in-patient on account of slight paralytic symptoms. The patient has suffered from gout, the last attack having come on two months previous to admission. A fortnight before admission, his manner was noticed as "strange"; and the next day he was found in the cellar where he worked acting as if warming himself before a fire; his manner was stupid; and he appears to have been in a "condition of reduction", probably sequent to an epileptic fit. He was taken home and kept his bed for a week; his manner was stupid, and he frequently made inarticulate sounds, but was not delirious. When admitted to the wards, he was able to walk well. His intelligence was fair, and there was no loss of sensation; but there was drooping of the right side of the face, and some loss of power in the right arm. His arteries appeared thickened and the arterial tension was very high, so that strong pressure was required to obliterate the pulse. The pulses of three other subjects of the same age as the patient were compared, and the hardness of the pulse was thus demonstrated. The ophthalmoscope showed double optic neuritis, specially developed in the left eye. The urine had a specific gravity of 1012, but was free from albumen.

Dr. Andrew considered the patient the subject of arterial sclerosis, due to his intemperate habits; the paralytic symptoms, following an epileptiform attack, due to his general vascular degeneration.

*Cirrhosis of the Liver, with Ascites.*—The patient, an elderly and ill-nourished man, had enjoyed fairly good health till 1872, when he was laid up for three months with pleurisy of the left side; since then, he has frequently been troubled with cough, especially during each winter. For six months before admission, he had been getting thinner

and weaker, and six weeks ago he had a violent attack of hæmatemesis; a fortnight after this, he was obliged to leave his work on account of failing strength, and his abdomen began gradually to enlarge. When admitted, there was copious ascites, and the superficial abdominal veins were enlarged; the abdominal distension prevented the liver being felt at that time. There were also some signs of consolidation at the apex of the right lung. Diuretics and vapour-baths were employed, but failed to lessen the ascites; paracentesis was then performed, and twenty-five pints of fluid were removed. After the tapping, the liver was found to be large, and the spleen could also be felt enlarged out of all proportion to the increased size of the liver.

The patient has been tapped five times in all within four months; the fluid now remains very moderate in quantity, and there appears to be less tendency to the return of peritoneal effusion.

*Salicylate of Soda in Acute Rheumatism.*—Dr. Andrew has used salicylate of soda largely in the treatment of acute rheumatism; and his experience gives grounds for the belief, that not only does this drug relieve the pain and lower the temperature, but also that it cures the rheumatism, and lessens the tendency to heart complication and other secondary inflammations. Generally the drug is given in twenty-grain doses every two hours for half a day; then the same dose is given every four hours; while later on, the dose is given but four times a day. By this method of using the drug, very satisfactory results have been obtained, and relapses have for the most part been avoided. The value of this drug in cases of osteo-arthritis appears more doubtful. In the employment of this drug, toxic symptoms have but seldom been met with; on their first appearance, the dose of salicylate is lessened, or the frequency of its administration is diminished.

*Hydatid Tumour of the Liver.*—A young man of healthy appearance complained of a swelling below the right ribs, which caused him some inconvenience. Four years previously, he had felt some discomfort in this situation, and, seven months before admission to the hospital, he had discovered the tumour for which he is now under treatment. According to the patient's statement, it had increased in size since then. On examination, a distinct, prominent, and rounded swelling was found to the right of the epigastric region; it appeared to be connected with the liver, but the liver itself was not enlarged. There was no pulsation felt, and no fremitus was obtained over the tumour; there was no tenderness and no jaundice. His general health was good; there were no signs of visceral or constitutional disease.

The case was diagnosed as one of hydatid of the liver, and the tumour was aspirated; nothing, however, was drawn off except an ounce and a half of blood. This was probably due to the trocar failing to reach the cyst. No disturbance or apparent alteration of any sort followed the operation, and it is proposed to repeat the aspiration.

##### DR. GEE'S WARDS.

*Acute Alcoholic Poisoning.*—A young man was admitted to the hospital in a feverish state, the cause of which was not apparent. A fortnight previously, he drank off a quart of gin, and this draught was followed by complete coma for some hours. Vomiting occurred on recovering consciousness; he felt ill, and was unable to walk. He had since been much troubled with frequent vomiting, but without pain or hæmatemesis; the bowels became costive. On examination, the chest appeared healthy, and the urine was normal; the abdomen was not tender, but it was distended. By means of percussion, the stomach could be mapped out distinct from the bowels; it appeared greatly distended. To further prove the distension of the stomach by gas, the method of "coin-percussion" was used: a shilling was laid flat on the abdomen, at the point most resonant over the stomach; this was then struck with another shilling, while the auscultator placed his stethoscope over a distant point of the stomach; a distinct metallic echo was thus heard, indicating gaseous distension of the viscus.

The case appeared to be one of acute gastritis, probably dependent on the irritation produced by the large dose of alcohol; but the diagnosis could not be made with much certainty, as such cases are not often seen in clinical practice.

#### SAMARITAN FREE HOSPITAL.

##### CONSULTATIONS.

MARCH 15TH.—*Ovarian Tumour complicated with Pregnancy.*—E. P., aged 32, had been pregnant a little over six months, and was also suffering from the presence of an abdominal tumour. The morbid growth was present during her first pregnancy three and a half years ago, and led to abortion at the fourth month of a second pregnancy in March 1877. Mr. Knowsley Thornton saw her a fortnight ago at her own home, and while recognising the doubtful nature of her case, was inclined to regard the abdominal tumour as ovarian, rather closely

connected with the uterus. A nodular mass felt in the pelvis to the right of and behind the uterus, he thought was probably the other ovary diseased. An adherent nodule, separate from the other pelvic tumour, has been discovered since, at the bottom of the pouch of Douglas. He advised her removal to the Samaritan Hospital, in order that he might see for himself the amount of suffering, and judge whether interference was necessary. During the fortnight she had been under his observation, increase in the size of the abdomen had been disproportionate to the enlargement of the uterus. She was markedly emaciated, especially about the face and chest, and was in constant suffering, only procuring partial relief and short sleeps with frequent opiates. Mr. Thornton now wished for the opinion of the staff as to the best course to pursue. He was himself decidedly in favour of making a small exploratory incision with careful antiseptic precautions, proceeding either to the removal of the tumour or to the mere raising of the pelvic portion, according to circumstances. He advocated this course as affording the best means of obtaining a perfect diagnosis, with the chance of complete relief and but little risk to the patient. The alternative course—induction of premature labour—would, if found necessary, still be available after the small exploratory incision had healed. The success which had attended ovariectomy during pregnancy, in the practice of Mr. Spencer Wells, rendered the course clear in any ordinary case as to the alternative of removal of the tumour or the induction of premature labour; but in this instance, there were peculiar difficulties.—Dr. GREENHALGH was in favour of an exploratory incision, with removal of the tumour if then found practicable. This was preferable to the induction of premature labour, to which he saw grave objections.—Mr. SPENCER WELLS admitted that this case was of more interest than ordinary cases of ovarian disease coexistent with pregnancy. He had himself removed ovarian tumours from pregnant women, with perfect ease and excellent results. But in this patient, from the character of the growth and the morbid conditions detected in Douglas's space, the operation would anyhow be difficult, and pregnancy much increased the risk. On the other hand, the patient was in a miserable condition, and some interference was imperative. The tumour was too solid for tapping, so as to give the patient temporary relief during pregnancy. The wisest course was to induce premature labour and to remove the tumour after the patient's recovery.—Dr. DAY, taking into consideration the nervous susceptibilities and the extreme discomfort from which the patient was suffering, considered it best that an exploratory incision should be made and the tumour at once removed, if possible. The great liberties which might safely be taken with the abdominal viscera under antiseptic precautions contrasted favourably with the admitted dangers of the induction of premature labour.—Dr. BANTOCK considered the case unfavourable both for operation and for the induction of premature labour, but had no objection to an exploratory incision under antiseptic spray. But if, on making that incision, it were found that the tumour could not be removed, considerable delay would be involved. On the whole, he was in favour of induction of premature labour.—Dr. CHAMPNEYS considered it advisable to wait for about a month and then induce premature labour; for both that course and ovariectomy were very hazardous at the present stage of the patient's illness; but at the seventh month, delivery would be attended with much less risk and would remove the main complication.—Mr. DORAN was of opinion that the sum of the dangers from induced premature labour followed by ovariectomy was rather greater than the total amount of risk involved in ovariectomy during the patient's present condition followed by natural labour.—Mr. THORNTON determined on abiding by his original decision, after duly explaining the patient's condition to herself and her husband, and speaking to them on the proposed alternative of induction of premature labour.

#### LINCOLN COUNTY HOSPITAL.

##### CASE OF VESICO-PROSTATIC CALCULI OF PECULIAR SHAPE, WITH PERFORATIONS FOR URINE.

(Under the care of Mr. T. SYMPSON.)

THE following case resembles, in some of its features, one well described by Mr. Rushton Parker in the JOURNAL for January 10th, and is in other respects extremely interesting.

An agricultural labourer, aged 44, was admitted into the Lincoln County Hospital, under my care, on March 7th, 1864, suffering from severe pain in the region of the bladder, incontinence of urine, and frequent desire to pass his urine, of which not more than an ounce could be retained in his bladder. By a sound passed *per urethram*, a stone was detected in the prostatic portion of the urethra; and, on rectal examination, a very irregular mass was felt, occupying the region of the prostate and neck of the bladder. About fourteen years pre-

viously, he had an attack of severe pain in his back, which lasted a few days and was accompanied by the appearance of blood in his urine. Since that time, he had suffered from all the symptoms of stone, had been in two or three infirmaries, and had been sounded, but without a stone having been detected until he became an inmate of this hospital in 1863, when he refused to submit to the performance of lithotomy, and went home. He had taken the "constitution water" with no other effect than that of relieving his pocket. The urine was neutral, specific gravity 1015, slightly albuminous.

A consultation was held on March 10th, at 11 A.M.; and after the patient had been anaesthetised by chloroform, lateral lithotomy was performed, and one large and two smaller calculi of very peculiar shape were extracted. At 2 P.M., some hæmorrhage had occurred, which was arrested by the application of cold water and the introduction of a *canule à chemise*. On the 12th, a little urine passed through the penis; on the 13th, the tube was removed; by the 18th, urine had been passed occasionally through the urethra; and by the 24th, the urine was passed in a stream through the urethra.

On April 5th, he complained of difficulty and pain in defæcation; and on the 11th, an escape of air was noticed through the wound of the operation, which had nearly healed. On digital examination, a communication was felt between the rectum and the incision. The fistula was laid open and stuffed with lint.

On June 5th, he still passed his urine frequently; but no stone could be detected on sounding.

On August 22nd, he was discharged cured, though he was still suffering from frequent desire to micturate.

He was readmitted into the hospital, under the care of one of my former colleagues, on January 9th, 1865, when he complained of inability to retain his urine for any length of time. The urine was alkaline and deposited mucopurulent matter. He was put upon quinine, meat-diet, and beer. On the 30th, he was made an out-patient at his own desire, having improved in general health, but his vesical symptoms remaining the same. The state of the bladder was not ascertained by sounding.

REMARKS.—The calculi I extracted were placed in the museum of the Lincoln County Hospital. Upon an examination of them recently, I found them to consist of two, which, when placed in apposition, in form resemble a Spanish chestnut, and are adapted one to the other by smooth concavo-convex surfaces. From each of the calculi project two long processes or spurs, one from the left side being broken off short. Near the upper surface of the left calculus runs a short canal, in size barely large enough to admit a No. 2 catheter (Engl.), continuous with a groove along the upper aspect of the right one. The lower part of the right calculus is also perforated by a canal, equal in size to a No. 1 catheter. In their natural position, the calculi measure two inches across from the tip of one spur to that of the other. Two of the spurs are five-eighths of an inch in length, one half an inch, and the broken-off one three-eighths of an inch. The calculi are almost white, with here and there patches of fawn-colour. According to the note in the museum catalogue, the right calculus weighs 108.5 grains, the left 94.5, and the broken-off spur 3.5; together, 206.5 grains.

From the history of the case, it seems probable that, some years prior to the admission of the poor fellow into the hospital, one or more renal calculi had descended into the bladder, and had then become wedged in the prostatic portion of the urethra; in which situation they increased in size by deposition of phosphates, whereby casts of the dilated ducts of the gland were formed—casts which now appear as those curious projections with which the calculi are studded. It is, however, somewhat difficult to understand how it happened that the presence of calculus should have so long been overlooked.

By the long-continued pressure of the points of the calculi, the tissues between the prostate and the rectum had become extremely attenuated; hence there is nothing surprising in the fact of these having become ulcerated some weeks after the operation, the wonder being rather that they did not give way sooner.

The continuation of the frequent desire to pass his urine, which was noted when he was last in the hospital, is probably to be accounted for by thickening and contraction of the bladder; it is, however, matter for regret that the presence or absence of stone was not then ascertained by employment of the sound.

DR. RAVOTH, a *privat-docent* in the University of Berlin, died on March 2nd, in his sixty-second year, of perforation by gall-stones. He was the author of several valuable contributions to surgery, especially with regard to intestinal hernia.—Dr. Orth, first assistant in the Pathological Institute of the University of Berlin, has been appointed Professor of Pathology in the University of Göttingen.

## REPORTS OF SOCIETIES.

## OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, FEBRUARY 6TH, 1878.

CHARLES WEST, M.D., F.R.C.P., President, in the Chair.

*Cancer of Uterus.*—Dr. MATTHEWS DUNCAN showed a specimen of general cancerous hypertrophy of the body of the uterus, the cervix remaining apparently unaffected. The patient, an old woman, died of acute suppurative peritonitis, the cause of which was not discovered. Her case was during life supposed to be one of uterine fibroid. She began to suffer only three months before her death; and her complaints were occasional pain in the hypogastrium, and occasional loss of blood *per vaginam*. Three weeks before her death, examination discovered a hard mobile tumour in the brim of the pelvis, about the size of the adult foetal head. After death, cancerous nodules were found in both lungs and in the liver. The uterus weighed about four pounds and a half; it measured eight inches in length, and six inches and a half in breadth. The length of the uterine cavity was six inches. The walls of the body were hypertrophied, fully an inch thick. Section generally presented the appearance of a section of scirrhus mamma. The lining membrane of the uterine body was thick and villous; at some parts destroyed. There was cancerous degeneration of the ovaries and of parts of the vagina. In the cervix uteri, the microscope discovered cancerous degeneration. The remarkable point in the case was the diffuse hypertrophy of the uterus, with very little change of shape, the whole body being uniformly affected with cancer of a hard scirrhus-like character; while the cervix was, on superficial examination, unaffected.

*Cancer of Uterus.*—Dr. ROBERT BARNES showed a specimen of cancer of the body of the uterus, from a patient who had lately died in St. George's Hospital. She had suffered for a considerable time from continued hæmorrhage, with, during the intervals, a fetid watery discharge. Suddenly, perforation occurred, and death from peritonitis. At the *post mortem* examination, the parts were found all adherent to the uterus. This organ was occupied by a mass of broken down cancerous tissues, probably of the epithelial kind. There were two perforations, one into the rectum, and one into the peritoneum. The cervix was unaffected.

*Epithelial Cancer of Uterus.*—Dr. CLEMENT GODSON showed a specimen of epithelial cancer of the uterus not affecting the cervical portion, but confined almost entirely to the mucous membrane of the cavity, only slightly invading the deeper structures. This history of the case was remarkable. The patient, aged 52, a well-nourished healthy-looking woman, of very florid complexion, had come under his care in St. Bartholomew's Hospital in December 1876. Her chief complaint was of intense pain in the region of the uterus, occurring almost regularly at ten o'clock every morning, and continuing for two, three, or four hours. The severity of the pain caused her to sit up in bed compressing her abdominal walls, while rocking herself to and fro, and frequently her cries were pitiable. Large doses of quinine, chloride of ammonium, and croton-chloral failed to give any relief, and the pain was only bearable when the patient was fully under the influence of morphia, which was administered hypodermically. On examination, the uterus appeared to be perfectly normal to the touch, and the appearance of the cervix uteri was quite healthy. The sound passed in to the extent of two inches and a half into a freely movable uterus, followed by a slight discharge of bright blood. There was occasional intermenstrual discharge of blood. The patient did not improve. She left the hospital in February; and died at home six months afterwards. The condition had remained much the same, except that during the last fortnight of her life a slight fetid watery discharge had been present. The *post mortem* examination disclosed nothing abnormal except a thickened shaggy condition of the mucous membrane. The microscope showed this clearly to be caused by epithelial cancer. Dr. Godson was of opinion that the woman had died worn out with the constant and irremediable pain.—Dr. ROGERS mentioned a case as bearing upon the subject under discussion. He was recently called in consultation to a lady supposed to be suffering from ileus. He found a large irregular uterine tumour pressing on and occluding the bowel. No complaint was made of any discharge from the vagina; the cervix appeared healthy. Colotomy was subsequently performed. The woman did not long survive; and, at the necropsy, the body of the uterus was found to be cancerous, while the cervix was apparently unaffected.—Dr. HEYWOOD SMITH mentioned that one of the specimens he exhibited at the last meeting of the Society was similar to those just shown, of cancer of the body only of the uterus. In his case, the cervix was not affected; there was not much pain; and there were also per-

foration at the fundus and an abscess connected with the bowel.—Dr. MURRAY remarked that the point of interest in the first two cases related was the absence of pain. He described a case now under his care where there was pain more or less severe. He advocated the use of the sponge-tent to clear up the difficulty of diagnosis in these cases; and he had used with benefit the perchloride of iron as a local application.—Dr. BARNES said that pain was often an early symptom in cancer of the body of the uterus. In cancer of the cervix, pain was frequently very late in appearing.—Dr. CHAMBERS referred to a case of cancer of the fundus uteri which he had brought forward at the Birmingham meeting of the British Medical Association in 1872. He had now a patient under his care in all essential points resembling it. He considered the pain, which in this case nothing but the hypodermic injection of morphia would relieve, specially characteristic of this form of disease.—Dr. EDIS mentioned a case he had lately seen in consultation similar to that brought forward by Dr. Matthews Duncan. On examination, the cervix uteri was found to be normal, the fundus greatly enlarged, and fixed in the pelvis. There was no offensive discharge, but there had been profuse hæmorrhage every month. The emaciation, the severe pain, and the sudden setting up of peritonitis, seemed to point to the case being one of cancer and not of fibroid.—Dr. HAVES observed that the greatest caution was necessary in the introduction of sponge-tents with a view to diagnosis. The tissues might be so thinned and softened as to be easily lacerated by dilatation. He remembered one case in which it had been arranged to introduce a tent, but fatal perforation occurred before this was done.—Dr. MURRAY said that the tent must be very long to injure the fundus. It ought to be short, and only used to dilate the os and cervix.—Dr. ROUTH was of opinion that Dr. Godson's case might have been benefited, if not cured, by more decided measures. From the *post mortem* examination, it was evident the disease was limited, and only affected the lining membrane; and he thought that, if a sea-tangle or sponge-tent covered with cotton and dipped in a strong solution of bromine had been used, the disease might have been destroyed, and a cure possibly effected. This was the plan usually carried out at the Samaritan Hospital. It did not seem to produce any bad symptoms, and was frequently very successful.—The PRESIDENT thought it would be very profitable if some Fellow of the Society would make carcinoma of the body of the uterus his special study, in order to provide a better guide towards diagnosis and treatment than was at present possessed. In concluding the discussion on this subject, he would add that he could not but regret that so few papers on the diseases of children and of women had been brought forward during the past year, for he was very reluctant to see the Society narrowing its scope and confining its attention merely to obstetrical subjects.

*Tumour connected with the Uterus.*—Dr. THOS. CHAMBERS showed a large tumour in connection with the uterus, which he had removed at the Chelsea Hospital for Women that afternoon. The patient was aged 36, and for the last five or six years had been suffering from many of the conditions supposed to be associated with fibroid uterus, especially hæmorrhage. She had been an in-patient in many hospitals, and had been subjected to various forms of treatment; and she ultimately came under his care at the Chelsea Hospital for Women in 1876. She was then at her monthly periods losing blood for fourteen or sixteen days; the periods were attended with great pain, and were followed for some days by leucorrhœa. On examination, the pelvis was found quite empty, the uterus occupying chiefly the right iliac region. The sound passed for six inches upwards, and to the right side; she was treated four months with hypodermic injections of ergotine, with the effect of reducing the monthly hæmorrhage from fifteen to six or seven days, and considerably relieving the pain. She was at the same time kept at rest, and fed upon a nutritious diet, and without stimulants. She left the hospital apparently better; but returned again a month ago, much increased in size, and suffering very considerably from hæmorrhage. On examination, it was found that the tumour on the right side had become associated with a companion on the left side. From the continued discharge, the character of the tumour and the size of the uterus as ascertained by the sound, it was argued that it was a case of fibroid uterus; but it was difficult to say why it had grown so very rapidly. The patient was examined by many medical men, who held different opinions as to the nature of the tumour, but all of whom thought it justifiable to make an exploratory incision with a view to its removal. This had been done that day, and the result was that the cavity of the uterus was found occupied by a growth of gelatinous consistency, and a huge mass of similar substance was connected with the left ovary and broad ligament. This had probably grown from the lower part of the left side of the uterus, with which it had a distinct fibroid connection. Though there were no adhesions, he had some difficulty in getting the growth out, and very great difficulty in securing the stump. He first transfixed and tied it with whipcord, both on the

right and left side. But, though the whipcord was very strong and had been tied very tightly, after the tumour was cut away the ligatures became perfectly loose. He, therefore, surrounded the whole stump with a single large ligature, which he tied as tight as possible, bringing out the ends at the bottom of the wound to serve for drainage purposes. He had seen the patient that evening, and she had then recovered from the effects of the chloroform, was free from sickness, and had a pulse of 84. In conclusion, he hoped that the tumour might be referred to a select committee, in order that it might be subjected to a thorough microscopical examination.—Dr. Galabin and Dr. Herman were then appointed to examine the tumour removed by Dr. Chambers.

*Inversion of Intestine through Umbilicus.*—Dr. ROPER showed a specimen of small intestine taken from an infant. The case occurred in the practice of Mr. William Toulmin of Upper Clapton. Some days after birth, the tissues round the umbilicus became inflamed. The funis did not separate until the fifteenth day, and with it came away a slough of the abdominal integument of the size of a shilling, leaving a deep ulcer. This was dressed with carbolic paste, covered by a pad of linen, and secured by a strapping. On the twenty-first day, a portion of intestine two inches and a half long protruded through the umbilical opening. At the same time, faeces passed from an opening in the bowel. The external protrusion was covered with mucous membrane. The case was, therefore, one where, after an artificial anus had been formed, the intestine became everted to the extent described, and thus protruded through the umbilical opening made by ulceration.

*Report of University Lying-in Hospital, Montreal.*—This report, communicated by Dr. MAC CULLAM, gave statistics and other information with regard to the cases of childbirth which had been treated in the University Lying-in Hospital, Montreal, between October 1st, 1867, and October 1st, 1875. The hospital consists of two wards, each with four beds; there is also a separate room for private patients; about 120 women were confined there every year. The patients were of much the same class as those received into maternity hospitals in other parts of the world. During the eight years mentioned, 995 women were confined in the hospital; of whom 987 made good recoveries, and eight died, seven of the deaths being due to puerperal fever, which prevailed in epidemic form in February 1871 and April 1872. Of the children, 948 were born alive, viz., 483 males and 465 females; and 47 were stillborn, viz., 35 males and 12 females. The average length of the male children was twenty inches; of the female, nineteen inches and a half; the average weight: males, seven pounds thirteen ounces; females, seven pounds eleven ounces. Instrumental interference was required in twenty cases, the forceps being used in nineteen, and the perforator in one. Of the cases in which the forceps were used, thirteen were primiparae. In the forceps operations, all the mothers recovered, and sixteen of the children were saved. In the one case in which the perforator was used, it was to diminish the size of a hydrocephalic head. Puerperal convulsions occurred in seven cases; all the mothers recovered, and five of the children were born alive. There was albuminuria in all the cases but one. Venesection was employed with the best results in two cases, and the only reason why it was not employed in other cases was that most of the patients admitted into the hospital were not in such condition as to bear depletion.—Dr. GODSON called attention to the average weight of the children recorded in the above paper. That of the males was seven pounds thirteen ounces; of the females, seven pounds eleven ounces. He had recently weighed a number of children delivered at the City of London Lying-in Hospital, and found the weight of the males averaged six pounds thirteen ounces, and of the females six pounds ten ounces; that was in each case a pound less than the figures given by Dr. Mac Cullam.—Dr. MURRAY said that, in the cases which he had noticed, where a small portion of membrane had been retained some days and then expelled, he had not seen the hæmorrhage described by the author of the paper. The membranes not being attached to the placental site, it was, he thought, difficult to understand how bleeding could result from their retention.—Dr. EDIS called attention to the fact that, in the above statistics, the stillbirths amounted to 5 per cent. of the children born—a very considerable proportion. It would be interesting to have some information as to the duration of labour in these cases. He also noted that instrumental assistance was limited to twenty cases; and he could not but think that, bearing in mind the size of the children, the large proportion of stillbirths might have been lessened had the forceps been more freely employed. He was convinced that the lives of numbers of children were sacrificed through hesitation to use the forceps.—Dr. ROPER said that the statistics of the Royal Maternity Charity did not countenance Dr. Edis's conviction; for, out of 2,409 confinements last year, forceps were applied in only seventeen cases, and the infant mortality was under 3 per cent. from all causes. He would call attention to the large proportion of cases of puerperal eclampsia and puerperal

mania in the Canadian statistics. The latter complication occurred three times in less than a thousand cases. But, out of 10,000 labours, he himself had only seen one case of puerperal mania. Again, seven cases of eclampsia had occurred in Dr. MacCullam's 995 cases, whereas in the eastern division of the Royal Maternity Charity, out of 2,409 women delivered in 1877, this disease only once made its appearance.—Dr. J. WILLIAMS thought that sclerotic acid—an active principle recently obtained from ergot—would probably be attended with even greater success than ergotine. He had not as yet made trial of it in *post partum* hæmorrhage, but he had used it in a case of large fibroid tumour with the result of arresting the bleeding, which was continuous, and diminishing the size of the growth; he found that it produced less irritation than ergotine. One grain of sclerotic acid would dissolve in six drops of water, and the dose was half-a-grain.—Mr. BROWN (Ealing) said that he would not think it right to allow a patient to remain without help for two hours after the os was fully dilated; he thought there could be no doubt as to the correctness of the practice recommended by Dr. Edis.

## HARVEIAN SOCIETY OF LONDON.

THURSDAY, FEBRUARY 21ST, 1878.

GRAILY HEWITT, M.D., President, in the Chair.

*Hydramnios.*—Dr. DE GORREQUER GRIFFITH gave an account of a case of hydramnios. It occurred in a multipara, who was pale and thin, and complained of pain in her back and stomach, which was worst at nights. She passed very little urine. She observed that she increased in bulk more rapidly than previously. The uterine tumour reached up to the ensiform cartilage. The waters burst, and pains followed. She was delivered of twins, both females. One was in an advanced condition of decomposition. Dr. Griffith reviewed the different theories of hydramnios, and especially its association with twin pregnancies.—This subject was taken up in the discussion which followed, and in which the PRESIDENT, Dr. ARTHUR EDIS, and Dr. CLEMENT GODSON took part; and Dr. GRIFFITH replied.

*Unsuccessful Ovariectomy.*—Mr. KNOWSLEY THORNTON read a paper on unsuccessful ovariectomy. He said he had learnt more from his ten unsuccessful cases than from his more numerous successful ones. Septicæmia was the great cause of mortality to be dreaded; and the adoption of the antiseptic treatment had improved the chances of life. Of the ten unsuccessful cases, seven occurred in his first twenty operations; two in the second twenty; and one in his third twenty cases. He had only had one death in his last thirty-three cases. He then gave an account of these ten cases. In one, there was fullness of the remaining vascular area, from the ovarian tumour becoming bloodless previously to its removal. The same thing was seen, but to a less extent, after tapping. In these cases, venesection full and free was often most effective. In another case, the adhesions to the liver and spleen caused injuries to these viscera, but the hæmorrhage ceased when the abdomen was closed; and, on *post mortem* examination, the injuries were found glazed over with lymph. In another case, there was hæmorrhage which might have been avoided. The pedicle was broad and spread out; and, when transfixed and ligatured, such pedicles are apt to slip, and bleeding to result. His last case had died of acute pleurisy. His conclusions were as follows. 1. Avoid tapping if possible, as it clouds the prognosis. 2. Operate early. 3. Examine every organ as thoroughly as the one to be operated upon. 4. Never operate without perfect antiseptic precautions—perfect in Mr. Lister's sense. Every student ought to be compelled to study the antiseptic treatment.—In the discussion which followed, the PRESIDENT, Dr. CLEMENT GODSON, Dr. HEYWOOD SMITH, and Mr. THORNTON took part.—In his reply, Mr. THORNTON said that Mr. Spencer Wells was prepared to adopt the antiseptic method of performing ovariectomy, if an improvement of only one per cent. could thereby be attained.

## ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

WEDNESDAY, FEBRUARY 20TH, 1878.

S. J. A. SALTER, M.B., F.R.S., President, in the Chair.

*Benign Tumour of the Lower Jaw.*—Mr. MAUNDER showed a benign tumour of the lower jaw, of the size of an orange, involving rather more than one-half of this bone. The operation was performed within the mouth: a method introduced and practised by Mr. Maunder on several occasions, so as to avoid section of important vessels and nerves. In this way, no external scar resulted, a great desideratum in the female.

*Observations on the Treatment of Compound Fractures of the Lower Jaw, with Notes of Cases.*—Mr. LYONS read a paper on the above subject. After remarking that the principal objects to study in the treatment of fractures in general were: 1. That union should take place between the fragments; 2. That the fragments should be placed in apposition to each other; 3. The avoidance of deformity; the author proceeded to allude to the various interdental splints, upon two only of which he would make any lengthened remarks. There were two great maxims needed in these splints, viz., that they should be simple in construction, and easy of adaptation. 1. The first splint on which he commented was Mr. Hammond's, consisting of a single iron wire, so formed as to fit round all the teeth, and a thin one passed through, entwining both teeth and outer wire; a pair of ordinary pliers being the principal tool required in its manufacture. Its adaptation is easy, and very effective in cases of single fracture. 2. The other apparatus was Mr. Gruning's, which was also very ingenious, although much more elaborate, and specially adapted for those cases where there were double and triple compound fractures, with great displacement. A full account of this splint was given in Mr. Christopher Heath's works on *Diseases of the Jaw*. The author then proceeded to relate eight cases of fracture, four of which he had treated with Hammond's splints with the best results. These splints had these advantages: there was complete immovability of the fragments; they were small in bulk; the mouth could be opened, permitting cleanliness (a most important element in the treatment of these cases); soft food could be masticated; and the patient could attend to his usual employment, if necessary.—The PRESIDENT, Mr. MAUNDER, Mr. BRYANT, Mr. COLEMAN, Mr. MOON, and Mr. RANGER spoke; after which Mr. LYONS replied.

#### ABERDEEN, BANFF, AND KINCARDINE BRANCH.

WEDNESDAY, FEBRUARY 6TH, 1878.

FRANCIS OGSTON, M.D., President, in the Chair.

*Treatment of the Third Stage of Labour.*—Dr. JAMIESON (Peterhead) read a paper on this subject. He began by saying that the three stages into which normal parturition had been divided might be described as three births, viz.: that of the os—its complete dilatation; that of the child—its entire expulsion; and that of the placenta—the extrusion from the contracting uterus of the entire secundines. These three stages were sometimes inverted in order, the third becoming the first, as in placenta prævia. Sometimes the third stage began before the second was completed; some abnormality existing in the presentation, which permitted the uterine contractions to detach the placenta before the foetus itself was dislodged from the uterus. The author gave a case illustrative of this, in which the premature dislodgment of the placenta was produced from the head being in the third position, with a foot in front of it and on the same plane. Immediate delivery of the child by the feet was required, and the placenta was found lying in the middle zone unattached, and presenting on extraction a blanched appearance. The third stage was a very important one, and should be provided for at an early period of the labour. The loss of blood during previous stages should be diminished, so that when the third stage arrived we might not be driven in desperation to styptics and oxytocics; and the resources of the uterus should be husbanded. A case was mentioned where a patient had been in labour, with fair pains, for twelve hours, but the head remained at the brim, even after rupture of the membranes; and the pains became weaker and the woman fatigued. The case would, if left to nature, have gone on for hours with scarcely perceptible progress, certain exhaustion, and unnecessary suffering; but, under chloroform, the long forceps completed the second stage with a very moderate degree of traction; and, vigour of uterine contraction having been secured, the third stage of labour was rendered safe. In the case noted, the hand was introduced into the uterus up to the fundus on the birth of the child, the placenta was seized at its distal extremities and extracted with the membranes attached without any hæmorrhage, the uterus contracting well. The author joined in the condemnation of the practice of dragging at the umbilical cord. Much mischief was often done by it; as, if the internal os had begun to contract while the placenta remained adherent to the fundus, traction on the cord would more than likely sever the connection between cord and placenta. He mentioned a case in which he found three-fourths of the placenta in the vagina, and the remaining fourth in the grasp of the internal os; and the insertion of the cord was at the distal end of the placenta in the uterine cavity. Pulling at the cord in such a case would have had the effect of stimulating the os to maintain its hold. Until the placenta was expelled and the uterus hard and firm beneath the hand, the attendant's vigilance should not be relaxed; and even then a sudden relaxation of the uterus might take place, or some portion of the placenta or mem-

brane might have been left *in utero*, the germ of future septicæmia. It was essential that the third stage should be rendered complete and thorough. There were many accidents which prevented this, or knowing we had accomplished it, without a manual examination of the interior of the womb. The placenta might be in detached cotyledons, and one might be missed; or the membranes might be so ragged and torn as to allow part to remain without any suspicion of the fact. The uterus did not contract as a regular sphere, but first at the internal os; and thus it was easy to see how any portion of the secundines detached or but slightly adherent to the main mass might be intercepted. Portions of the membranes were frequently grasped while the placenta was being extruded. The longer the placenta remained in the uterus, the greater was the amount of blood issuing from the sinuses; as, until the placenta was removed, the uterus could not complete its contraction. The old doctrine of the whole uterus being denuded of mucous membrane must be given up, the only part left bare after parturition being that to which the placenta was attached; and this was the only part specially liable to septic influences. There was nothing very daring, then, in the mode of treatment he proposed, which was, in every case of labour, after the second stage was complete, the cord tied, and the child removed, to pass the hand up to the fundus of the uterus cautiously, pressing gently against the internal os if impeded by it, and sweeping entirely the interior of the organ, so that nothing could be left of an injurious character, and inducing natural action if the contractions are feeble or irregular, the other hand being at the same time placed externally on the fundus. If the placenta were found lying in the vagina, it was unnecessary to carry the hand into the uterus; but the hand in such a case should be carried up to the internal os to make sure none of the membranes were imprisoned by it, and, if they were, the os was to be gently pressed and the fingers closed on the membranes, so as to "slide" them free. When the placenta was found half within and half outside the os, the sooner release was effected the better, for the part inside, being detached from the uterine wall, was preventing the contraction of the uterus, and so allowing avoidable hæmorrhage to go on. In such a case, gentle pressure on the os readily permitted the entrance of the hand, which, reaching the distal portion of the placenta, swept it away along with the rapidly forming clots. The kind of placenta in this position was usually that consisting of straggling cotyledons. It was necessary to introduce the hand early, as the os internum began to contract very soon after the expulsion of the child, and imprisoned the secundines either wholly or partially. If the hand were introduced at once, little blood was lost; and this was in striking contrast with cases in which the placenta had to be removed some time after the birth of the child. Again, in cases of early removal of the maternal face of the placenta, the membranes contained scarcely any blood; while, on the other hand, after delay, they invariably contained coagula of more or less size. The membranes were sometimes an obstruction to the investigating hand, which should be insinuated and turned in such a way as to avoid them. When the os internum was obstinately obstructive, the fingers were to be rested against it cone-shaped till it yielded, which it did gradually; and then the hand was to be insinuated gently, the other hand grasping the fundus externally. After everything had been removed, a tightly rolled-up petticoat, made into the form of a cylinder, was to be placed against the dependent side of the abdomen, the woman being cautioned to keep close to it. The author alleged of his method: 1. That it preserved the life-blood of the woman; 2. That it obviated the chance of inversion; 3. That it defeated the possibility of those terrible occurrences which produced septicæmia, and too often ended in death. He allowed that pain was produced by his method, but maintained that this was but another pang of the second stage, which was soon over, except in those cases where it must have been had recourse to at a later stage, when the pain would have been increased tenfold and the difficulty much greater. The single pang gave an immunity from dangers dreaded by experienced practitioners more than any of the pangs of childbed.—Dr. JACKSON thought Dr. Jamieson dreaded a little rest after the second stage too much. He would never thrust his hand into the uterus at once. The fibres required a little time to rest before contracting firmly. He had never seen any harm from waiting, and thought the chance of hæmorrhage less by doing so. He generally did a little shampooing and pressed gently, and waited till the nurse washed the child, when, on examination, the placenta would probably be found in the vagina, in which case all that was required was to withdraw it, the finger being introduced far enough up to see that all the placenta was free. If the placenta were still in the uterus, he introduced his hand without hesitation, but had found this attended with some difficulty, and requiring time and care. He had never seen any injury from plucking away the adherent placenta in so far as septicæmia was concerned, and did not think the risk of that was an objection to

Dr. Jamieson's plan; but he thought there might be danger from hæmorrhage.—Dr. COWAN held by the old rule in uncomplicated cases, to wait twenty minutes, and to use gentle traction on the cord. He considered the binder good, if properly put on, and most patients experienced great comfort from it.—Dr. ALEXANDER OGSTON thought that, though at first sight it seemed repulsive to introduce the hand, yet that proceeding cleared away everything. Could Dr. Jamieson say how long he had tried this plan, and his mortality as compared with former experience? He himself had within the last year seen two cases with excessive after-pains, and in which the uterus was very much larger than usual. He had squeezed the uterus in these cases and given it a backward direction, and had found the organ take up a new position, with instant relief to the pains and without the discharge of any clots. The bandage he thought useful. He knew it was so in surgical cases.—Dr. STEPHENSON said that all were not prepared for the startling innovation proposed. All were agreed on the importance of the third stage, and on the importance of the effect of the first and second on the third. One rule Dr. Jamieson did not mention, which he (Dr. Stephenson) thought of great importance, viz., to have the hand firmly on the uterus, and to follow it down and not relax till the organ was fully contracted. If this were done, the placenta would generally be found in the vagina. A long first stage was specially apt to cause difficulty with the placenta. The uterus did not begin to contract at the internal orifice, for then the placenta could not be expelled. The rule was that the fundus first began to contract. In rare instances, the os contracted first, but this was from exhaustion or some other abnormality. He denied that hæmorrhage was usually, or, as a rule, continuing till the placenta was expelled. The placenta might be in the uterus for hours without hæmorrhage. If the position of Dr. Jamieson on this point were correct, it followed that the blood must either pass or the uterus be distended, but neither of these occurred. He considered the best method was the shampooing, *i.e.*, holding the hand over the uterus with gentle pressure without rubbing. As soon as we could feel the edge of the placenta by the forefinger introduced into the uterus, then we might with safety gently withdraw it by pulling on the cord in a proper direction. The introduction of the hand was dangerous and unnecessary. There was the risk of introducing new septic matter and also air. The only advantage was thorough clearing of the uterus of clots, etc.; but, within half-an-hour of this being done, more or less blood would have oozed out again, so that the uterus could not be kept clear. In regard to Dr. Alexander Ogston's surprise that the uterus was so large as he had found it and half or entirely up to the umbilicus, he (Dr. Stephenson) had to point out that this was the natural condition on the second day after delivery. Severe after-pains bringing peritonitis he had not seen, but peritonitis was often really present when after-pains only were supposed to be so. He could not account for the relief in Dr. Ogston's cases, but removal of pressure was the probable cause of cure. He earnestly hoped the author's recommendation would never be followed. He thought the binder very useful, and the comfort of the patient increased by it.—Dr. F. OGSTON, junior, thought there was no danger in admitting fresh air. In one case, he regretted he had not adopted Dr. Jamieson's suggestion. He had twice delivered the same patient, and had, owing to severe after-pains, introduced the hand, removed the clots, and relieved the patient; but on the third occasion this procedure had not been adopted, and the patient died.—Dr. SMITH-SHAND had long been in the habit of waiting twenty minutes or half-an-hour, and had often had difficulty in removing the placenta, but of late he had had recourse to the method advocated by Dr. Stephenson, and since then he had seldom had any trouble. He should not be inclined to introduce the hand as proposed. He could not agree with Dr. Jamieson that the binder was useless. Everything depended on how it was put on.—Dr. F. MOIR said he had attended one of those who had formerly been treated by Dr. Jamieson without a bandage, and she had expressed a decided preference for the bandage.—The PRESIDENT would not introduce the hand without good reason. The binder he considered valuable. He did not think moderate after-pains injurious.—Dr. JAMIESON, in reply, said he did not expect to find his procedure accepted. Dr. Stephenson had asked if patients objected, but he had not found this to be the case. He kept the patient at rest, and supported the abdomen against his roller, and thought that that was better than the bandage, and more natural. The lower animals did not need a binder. He could not see the analogy between surgical and obstetrical cases as far as the binder was concerned, as in the former there was a distinct solution of continuity of the wall. He had adopted his present plan three years ago, and had had no death since, and the recovery had not been less favourable than before; the lochial discharge had been less, and the patients had been able to sit up for necessary purposes on the second day, which he always advised. He had had to congratulate himself

on his new plan, but never to regret it. No doubt, if they waited for half-an-hour or more, then introduction was more difficult, but there was no difficulty if done within five minutes or so. He never meant to say that the os internum contracted first, but merely that this was the most obstructive and dependent part, and was felt more readily. After the hand was passed through the contracting os, there is plenty of room, even though the fundus and walls were contracting. He thought the large tumour, as discovered by Dr. Ogston, was slight anteversion pressing on the bladder or some sensitive part, and the movement might have relieved flexion or pressure. Hæmorrhage need not flow on steadily, but by early extraction there was better contraction and less loss of blood, as he had seen by experience. He thought he saved six ounces of blood to every woman. He thought his patients preferred being without the binder.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, FEBRUARY 9TH, 1878.

J. W. MOORE, M.D., and subsequently JOLLIFFE TUFNELL, F.R.C.S.I., Vice-President, in the Chair.

*Diaphragmatic Hernia.*—Dr. T. E. LITTLE presented a specimen of this lesion from the body of an elderly female (sixty or seventy years of age), of whose case there was no clinical history. There was marked angular curvature of the spine in the lumbar region. On raising the sternum, a tumour as large as a small closed fist was found occupying the lower part of the anterior mediastinum. It was composed of a sac of peritoneum containing a portion of intestine and of omentum. An opening, almost circular, and with well-defined, sharp, yet somewhat thick edges, existed in the diaphragm, behind and to the left side of the xiphoid cartilage. The hernia was composed of fifteen inches of the transverse and descending colon. There were no adhesions connected with the gut, but its surface was marked by two constrictions indicating the points where the intestine became involved in the hernia. Dr. Little observed that diaphragmatic ruptures had three modes of origin, namely, (1) congenital, (2) traumatic, and (3) acquired, from yielding of some weak point in the muscular structure of the diaphragm. The traumatic origin of the hernia in the present case was inadmissible. Very few congenital herniæ were found at such an age. Hence the case was one where a hernia developed at a point at which there was naturally a deficiency of muscular fibre in the diaphragm, namely, between its muscular attachment to the ensiform cartilage and the last true rib.—A very interesting question arose as to the influence of the angular curvature of the spine in causing the hernia by upward pressure of the contents of the abdomen. It was also noteworthy that the hernial sac was in close proximity to three serous membranes—the pericardium, the pleura, and the peritoneum.

After a brief discussion, the SECRETARY (Dr. E. H. BENNETT) read a communication from Dr. WILLIAMS of Liverpool on a remarkable case of Venous Occlusion.—The Society then adjourned.

#### SURGICAL SOCIETY OF IRELAND.

FRIDAY, FEBRUARY 1ST, 1878.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

*Excision of the Knee-Joint.*—Mr. TYRRELL made some remarks on this subject. He confined himself chiefly to speaking of the after-treatment. He had been most successful with all the cases he had operated on; and, therefore, he wished to bring the method adopted by him under the notice of the Society. Mr. Tyrrell had been in the habit of performing Heron's operation up to the year 1874, when he adopted the new method. He used a splint, which consisted of two pieces of wood, grooved in the shape of the parts, joined together by a crank of iron. The wooden portions were not made in the same plane. The chief credit of this splint was due to Mr. Hayes of the Mater Misericordie Hospital. Mr. Tyrrell preferred making his incision in a straight line below the patella. A small saw with a movable back he considered to be better than any other kind for this operation. He considered that the chief item in the after-treatment consisted in the perfect immobility of the limb. Having applied the splint before referred to, he put on a double layer of flannel bandage from the toe up to immediately below the seat of operation, and another double layer from the thigh down to above the seat of incision. Instead of muslin, Mr. Tyrrell used stout flannel well starched, as he considered the muslin far too easily torn. The flannel should be put on with great force, so that it might fit close to the limb. A small piece of tubing or horse-hair was placed across the wound, and muslin and tow being placed over it, the operation was completed. Twenty-one cases had been treated by this method in the Mater Misericordie Hospital, and none of them had proved fatal; in fact, with one or two exceptions, the success was com-

plete.—The PRESIDENT had been so much impressed with Mr. Tyrrell's after-treatment of excision of the knee-joint that he had tried it with slight modification, and the result was all that could be desired.—Mr. O'GRADY had tried Mr. Tyrrell's plan of treatment. Having previously applied an Esmarch's bandage to the limb, he found that when reactionary hæmorrhage came on (as was often the case after Esmarch's bandage had been applied) it was most tedious to undo the dressings, as the starched bandages became fixed and difficult to be opened.—Mr. TYRRELL had used Esmarch's bandage since the method became known, and never had experienced any difficulty about hæmorrhage. He considered that, if the operation were performed very slowly and the dressing not put on for some time, all the difficulty in the matter would disappear.

*Some of the Ways in which Fevers begin, with some Remarks on the Treatment of Fevers in the present day.*—Dr. HENRY KENNEDY read a paper on these subjects. He said that it was most interesting to study the various and unaccountable ways in which he had known fevers to begin. His attention had been drawn specially to this subject by some cases which had lately come under his care, in which the patients had merely complained of neuralgic pains and had been treated for such. Bronchitis was also a way in which he had known fevers to begin; acute rheumatism another. Dr. Kennedy did not approve of the practice of leaving fevers to themselves, merely supporting the strength. He thought that it was the duty of a physician who knew that certain inflammatory changes were going on, to combat those changes. Dr. Kennedy thought it would be useful to reduce the quantity of stimulants and milk in fevers, as he believed that these were very often given in excess, and proved injurious instead of beneficial.—Mr. F. T. PORTER, Dr. BIGGAR, Mr. WHEELER, and the PRESIDENT made some remarks on the subject of Dr. Kennedy's paper; and the proceedings then terminated.

#### MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, FEBRUARY 6TH, 1878.

FREDERICK A. HEATH, M.R.C.S., President, in the Chair.

*Plica Polonica.*—Dr. SIMON showed a specimen of plica Polonica, removed from the head of a Polish woman resident in Manchester. The plica dated its origin from an illness whilst in Poland ten years ago, during which the patient's hair had been neglected, and subsequently to which, from superstitious credulity, the tangled mass of hair had been allowed, and even encouraged, to remain. The plica was nine inches in length, and consisted of an axial mass of *débris*, sparsely encircled by normal curling hairs, and covered by nits. There was no evidence to support a theory of parasitic origin, nor was separation of the plica attended by pain or oozing of bloody or other fluids, as was believed to be the case by some English dermatologists. Similar plicæ had been removed two or three years ago from various parts of the scalp, but in other respects the patient was cleanly, and her hair well kept. She acknowledged a belief in the "safety-valve" action of the plica, and parted with it most reluctantly.

*Gastrostomy for Stricture of the Œsophagus.*—Mr. BRADLEY related a case of gastrostomy in a boy aged 15, who had inadvertently swallowed some caustic soda four months before. The resulting Œsophageal stricture was so tight that it was found impossible to pass any instrument into the stomach. Gastrostomy was accordingly performed on November 17th, 1877; and on the second day the boy was fed through the gastric opening. He suffered very little inconvenience from the operation, which was not followed by peritonitis or any other untoward symptom; but it was found impossible to administer sufficient food to nourish him, though the stomach-feeding was supplemented by three nutritive enemata daily. He sank on the twenty-eighth day following the operation, clearly dying of inanition, and in a state of the most extreme emaciation. The stomach was found to measure five inches by two after death, and at the pyloric end was studded with small ulcers.

*Localisation of Cerebral Disease.*—Dr. DRESCHFELD brought forward three cases of brain-disease, where the affection was situated in the anterior lobes of the brain, and where the symptoms during life presented such uniformity that a correct diagnosis as to the localisation of the lesion could be made *intra vitam*. Generalising from these cases and from an analysis of other cases published, Dr. Dreschfeld drew attention to the following points as important aids to a correct diagnosis. 1. Convulsions are often present, and show certain peculiarities; they are ushered in at once by loss of consciousness without a preceding aura; the convulsive stage is very short, while a prolonged stage of insensibility follows the fit. 2. Motor and sensory paralyses are absent, unless the disease extends into or affects the motor sphere (bounded on the surface of the brain by the ascending frontal and ascending parietal and supramarginal convolutions, and in the in-

terior of the brain by the corpus striatum, the thalamus optici, internal capsule, and radiating fibres of the corona). 3. Headache is constantly present. 4. Certain psychic symptoms are always present, such as mental apathy, torpor, somnolence, and dementia; violent delirium or maniacal excitement, on the other hand, has only rarely been observed in lesion of the anterior lobes. 5. Vomiting is much oftener absent than present; and the same is the case with optic neuritis. Lesions involving the inferior frontal convolutions of the left side produce, besides the above symptoms, also aphasia.

*Removal of the Tongue.*—Mr. LUND showed a patient, whose tongue he had removed with a scissors. The particulars of this case have already appeared in the JOURNAL of February 9th.

*Cerebral Tumour with Aphasia.*—Dr. ROSS read a case of cerebral tumour with aphasia. The subject was a boy, aged 4, who entered the Southern Hospital four months ago, suffering from right hemiparesis, aphasia, and double optic neuritis. He also suffered from unilateral convulsions, of which he had had twenty attacks in ten days. The nurse reported that the convulsions were confined to the left (healthy) side; that they were ushered in with a scream; that, during an attack, the body was drawn so that the left side of the face almost touched the left ankle (pleurosthotonos); that the duration of the attack was only a few seconds; and that there was no loss of consciousness and no subsequent drowsiness. The further symptoms which developed during the progress of the case were nystagmus, amaurosis, progressing from right to left, temporary conjugate deviation of the eyes, and rotation of head to the left side. The right hemiparesis passed on gradually to complete hemiplegia, with contractions of the muscles of the arm and leg during waking hours. Dr. Ross pointed out that the contractions of the right leg and arm, and the accompanying hemiplegia, showed that the fibres which connect the vertex of the brain and the grey matter of the anterior horns were interrupted in their course. They were probably interrupted by a tubercular tumour situated in the white substance of the left hemisphere above the lenticular nucleus, so as to interrupt also the fibres of the corpus callosum which connect the left and right third frontal convolutions. A tumour situated in this situation would account for the aphasia and paralytic symptoms; but, in order to account for the remaining symptoms, it was necessary to assume the presence of a second tumour situated in the left lobe of the cerebellum. Dr. Ross said that the case was still *sub judice*, but probably some day an opportunity might be afforded of verifying the diagnosis.

#### GLASGOW MEDICO-CHIRURGICAL SOCIETY.

FEBRUARY 15TH, 1878.

J. MORTON, M.D., in the Chair.

*Obstruction of the Bowels.*—Mr. J. S. NAIRNE read notes of a case of obstruction of the bowels, with extraordinary flatulent distension.—Dr. HUGH THOMSON said the absence of symptoms of previous constipation in the case related was of interest. He would have been inclined to recommend earlier operative interference than had been adopted.—Dr. W. L. REID mentioned a case in which he had twice penetrated the colon on account of great flatulence, with decided relief to the symptoms.

*Hydatids.*—Dr. J. L. MILLER (Tasmania) read a paper on hydatids, in the course of which he mentioned four cases which had come under his observation, in three of which tapping the cysts by means of a long trocar had been followed by the best result. One of these was of considerable rarity. A gentleman complained of increasing difficulty in micturition, and each time the catheter was passed a smaller size was required, until finally the urethra became occluded, and puncture of the distended bladder was determined on. This was done, and, instead of ammoniacal urine flowing from the cannula, a large quantity of clear pellucid fluid escaped, and immediately the urine was passed by the natural channel. The fluid proved to be from a hydatid cyst which had been pressing on, and probably growing in, the bladder.—Dr. SCOTT ORR stated that he had treated three cases of hydatids of the liver. He recommended puncturing and drawing off the fluid; in one of his cases, he had to repeat the operation, and the fluid at the second tapping was tinged with bile.—Dr. CHARTERIS asked Dr. Miller as to his theory of the entrance of the parasite into the system, as also as to the rate of growth of the tumour.—Dr. WHITTAKER asked whether the fluid had been examined to ascertain the presence of echinococci. He had examined the brain of a sheep which died of "shindy", and found vesicles in the left ventricle.—Dr. MILLER stated that Dr. Bird's theory as to the infection of the lungs was the inhalation of the dust of the street. In Australia, the water-supply is limited, and men and dogs drink at the same stream. The time required for development of the tumour was uncertain; and, as regarded the echinococci, he had found them in some cases, but the character of the fluid was sufficient to establish the diagnosis.

## BRITISH MEDICAL JOURNAL.

SATURDAY, MARCH 23RD, 1878.

## THE GOVERNMENT MEDICAL ACT AMENDMENT BILL.

WE reproduce in another column *in extenso* the Medical Acts Amendment Bill, introduced into the House of Lords by the Duke of Richmond on Tuesday evening, from an early copy with which we have been favoured. We publish also a *verbatim* report, taken specially for this JOURNAL, of the Duke's speech in explanation of the Bill in introducing it. With these ample elements for forming an opinion before them, our readers will not require much further comment or explanation at present. The Bill will, no doubt, immediately come under the cognisance of the Medical Reform Committee, who have probably put themselves in communication with the Government during the course of the preliminary proceedings, which have resulted in the introduction of this Bill.

It will be seen, however, that this Bill as introduced differs very seriously, as we had some reason to fear, and as we intimated might be the case, from the draft submitted to and approved by the members of the Executive Committee of the General Medical Council, who were consulted semi-officially and in their individual rather than in their official capacity. It is understood that the alterations that have been introduced are of a kind which will not meet their views, and they are, we imagine, likely to encounter the serious opposition of the profession at large. So far as our Association is concerned, three important principles of reform have been affirmed at general meetings: the first, uniformity of examination and reciprocity of practice, on the principle mainly contended for by Sir Charles Hastings in influencing the framing of the first Medical Act; second, the principle of the direct representation of the profession in the General Medical Council—specially contended for by the Association when Lord Ripon framed his Medical Act Amendment Bill of 1870; and third, the amendment of the penal clause, with a view to protect the public and the profession from the extensive inroads and dangerous practices of unregistered quacks—a principle included in Lord Ripon's Bill, and strenuously reaffirmed at the last annual meeting of the Association. As the Bill was first framed and approved by the Executive Committee of the General Medical Council, and in the draft condition of which we spoke of it before it had been officially revised in the Cabinet, the present Bill included a complete scheme for conjoint examinations in the three kingdoms, thereby securing a complete adoption of the principle of uniformity of minimum examinations, and also the third principle. The second, that of a direct representation of the profession in the Council, has not, we believe, at any stage been included in the draft of this Bill.

It will be seen that, in the Bill actually presented to Parliament on the authority of the Government by the President of the Privy Council, the machinery for enforcing conjoint examinations in the three kingdoms is abandoned, and the reason is probably pithily summed up in the words used by the Duke, "There is a difficulty in Scotland". It will be remembered that that difficulty has repeatedly been put forward by the representatives of the Scotch bodies in the General Medical Council, and was very forcibly and fully expressed by Sir Robert Christison, the then President of the British Medical Association, in his address to the Association at its Edinburgh meeting. In place of the Conjoint Board scheme, which is favoured only by permissive language, this Bill presents a scheme for enforcing uniform examinations by each body, by rules to be laid down by the General Medical Council, having a more peremptory authority than any of the regulations

that body has at present power to frame in respect to the authorities. Thus, it is held out, an adequate degree of uniformity will be procured and competition downwards will be stopped. Such machinery, however, is obviously open to so many difficulties and complications, and likely to be so much impeded and resisted in its action, as to be of very doubtful value. A valuable supplemental provision requires that every person asking to be registered shall have both a medical and a surgical qualification. The Duke spoke with warm approval of the conjoint scheme of examination for England, which certainly merits high approval; on the other hand, the right which the Bill proposes to give to women to claim examination at the Conjoint Board, and in virtue of such examination to claim a registrable title from each of the bodies participating in such conjoint examination, is likely to create a fresh obstacle to the fulfilment of his wish that the conjoint scheme may come into speedy operation. The College of Physicians, by a vote on Monday last, indicated its intention to resist any such bestowal of any of its registrable titles; and it is probable that the College of Surgeons may take the same course. At any rate, this provision of the Bill will impede rather than favour the formation of a Conjoint Board in the only country in the United Kingdom in which the medical authorities seem at present disposed to form such Conjoint Board.

The clauses amending the fortieth clause are, we consider, satisfactory, and will afford a long and urgently needed protection, as desirable in the interests of the public as of the profession, and most urgently needed in the interests of both. The Bill includes many useful provisions relating to the registration of colonial and foreign degrees, and the machinery for striking off unworthy members from the *Register*. It will be seen that added to it are schemes for the registration of dentists and for the registration of midwives. Except that some persons may object to the close connection into which this scheme brings dentists and midwives with the *Medical Register*, these schemes appear to be well considered, and, as such, have been approved in principle by the Parliamentary Bills Committee of our own Association on former occasions, and by the Obstetrical Society of London in respect to midwives, and by the Odontological Society in respect to dentists. These, however, are not essential parts of a Medical Act Amendment Bill. Useful in themselves, they are rather supplementary to than parts of medical legislation. It is not a little remarkable that this Bill should, in the course of a week or ten days, have undergone such serious changes in respect to some of its most important provisions; these changes, it must be observed, being not mere matters of detail, but important matters of principle. There is, of course, some Polonius behind the scenes; but it is not certain that he will answer the challenge to come out. The Duke of Richmond has been at great pains in this matter, and has done his best to satisfy opposing views; but we fear that the Bill, in its present state, will cause much disappointment, and, even if the Government should succeed in passing it, will hardly be generally accepted as a final settlement of the question.

## THE ANTISEPTIC METHOD IN OVARIOTOMY.

DR. CARL SCHROEDER, Professor of Obstetrics and Gynaecology in the University of Berlin, has just published in the *Berliner Medicinische Wochenschrift* a highly interesting and valuable communication on the subject of ovariectomy. From May 25th, 1876, to February 24th, 1878, he has operated in fifty cases, which he summarises in a table, to which he adds comments. From the total cases, three must be deducted in which the patients were the subjects of cancer, and died, in consequence of the extension of that disease, on the tenth, nineteenth, and forty-fifth days after the operation. In the remaining forty-seven cases, there were seven deaths; *i.e.*, 14.9 per cent. of deaths and 85.1 of recoveries. On dividing, however, the table into two equal parts, it is found that (excluding the three cancer cases)

the first twenty-four operations were followed by six deaths=25 per cent., and the last twenty-three by only one=4.3 per cent. This great reduction in the mortality, Dr. Schroeder says, may be attributed to improved skill on the part of the operator; but he attaches much greater importance to the avoidance of infection, which he regards as almost exclusively the cause of death after ovariectomy.

As regards the places where the operations were performed, thirty-three patients were operated on in the Lying-in Institution in Berlin, twelve in private houses, and two in the Charité Hospital. (The three cases of cancer all occurred in the Lying-in Institution.) Of the thirty-three patients in the Institution, only one died=3 per cent.; while the mortality among the fourteen operated on elsewhere was six=43 per cent.

Dr. Schroeder says that the low death-rate in the Lying-in Institution is very remarkable, when the circumstances are considered. The institution was originally a private house; the wards are defective in their sanitary arrangements, and are always overcrowded by one-half of the normal number; women with offensive discharges are often admitted; and, under all the circumstances, the occasional occurrence of puerperal fever is unavoidable; and hence a more unfavourable place for ovariectomy could scarcely be conceived. Yet, among thirty-three patients, there was only one death; and this was not from infection, but from intraperitoneal hæmorrhage, which proved fatal on the nineteenth day.

The key to this success, Dr. Schroeder says, lies in having so perfect a control over the persons and instruments concerned in the operation, that infection is warded off from the subjects of operation. The operations are performed in private rooms, into which parturient women are never admitted, and suppurating cases only rarely. The instruments to be used are always freshly cleaned by the instrument-maker, and allowed to lie in a five-per-cent. solution of carbolic acid; the sponges are quite new, and are always most carefully cleaned and scalded on the preceding day by the head midwife, and placed during the night in solution of carbolic acid. At the operation, five persons are present besides the assistant who administers chloroform. The operator and one assistant only come into contact with the wound; a second assistant has charge of the instruments; the head midwife mixes the solutions and renders occasional assistance; and a nurse stands beside the operator with a vessel containing carbolic acid solution. The head midwife is required to avoid coming into contact with all sources of infection; and the nurse is detailed for duty in the ovariectomy wards exclusively. Dr. Schroeder and his assistants take the greatest pains to avoid all contact with infective materials.

The operation is always performed in the morning, before any other patients are visited: at half-past seven in the summer; in winter, as soon as it is sufficiently light. On rising, Dr. Schroeder takes a bath, dresses himself so that his clothes may not convey infection, and washes in carbolic acid solution before proceeding to operate. At least half an hour before the operation, the carbolic acid spray is brought into play in the room; and then, the patient having been washed in a pure atmosphere, the operators proceed to their work with clean hands and clean instruments. These precautions are, in Dr. Schroeder's opinion, sufficient to obviate the risk of peritonitis, which, in its generalised form, he holds to be the result of infection and not of injury.

Even in the most severe cases, and in those where the peritoneum was extensively interfered with, there was scarcely any reaction. The pulse, indeed, rose to 90 or 100; but the temperature never exceeded 100 Fahr., or sometimes on the first evening 100.4; not uncommonly it remained absolutely normal. Even in one very difficult case of suppurating cyst with extensive adhesions (followed by recovery), the temperature did not exceed 98.8 during the first ten days.

In a foot-note, Dr. Schroeder remarks that there is, as a rule, a fall of temperature, sometimes as low as 95 Fahr., immediately after the operation. This, however, has never been followed by any ill result. He has never seen indications of carbolic acid poisoning, nor has he found in any case carbolic acid in the patient's urine.

Vomiting, dependent on the anæsthesia, is very common on the day after the operation, and rarely continues beyond this. On the second or third day, the appetite returns. The dressings are allowed to remain nine days; on the tenth, they are removed under the carbolic acid spray, and the sutures are taken out. The wound is found to be united by the first intention, without the formation of a drop of pus. The pedicle is always returned into the abdomen, as the retention of it outside the wound interferes with the application of Lister's dressing. Silk sutures certainly irritate; but Dr. Schroeder does not know how to do without them, as catgut, he says, is not to be depended on, and he has no faith in the actual cautery. He used drainage of the peritoneum in only one case, and considers that it is never necessary, and sometimes even injurious.

This communication of Dr. Schroeder is a most valuable contribution to the settlement of the question as to the applicability and utility of the antiseptic method in ovariectomy. He heads his paper, "A Report on Fifty Listerian Ovariectomies (*Lister'sche Ovariectomien*)"; but, though he describes minutely the antiseptic precautions employed, he does not give details as to the manner in which the wound is dressed—merely speaking of the "*Occlusivverband*". Anyhow, his results go to prove the applicability to ovariectomy, if not of Lister's method in all its minutest details, at least of a modification of that method.

#### SURGICAL TREATMENT OF STONE IN THE BLADDER.

SIR HENRY THOMPSON'S paper at the last meeting of the Royal Medical and Chirurgical Society, in which he gave the pith and marrow of his experience derived from the treatment of five hundred cases of stone in the bladder of the male adult, is unique in the history of surgery. The profession has never before been presented by one man with such extensive, exact, and laboriously acquired information on the subject of stone in the bladder. With but few exceptions, the author showed to the Fellows on Tuesday night every stone he has removed, either by lithotripsy or lithotomy. On the table was placed a schedule containing all the essential particulars of each case, with numbers corresponding to the specimens. Such an arrangement must have required immense care and attention to detail, and would have been almost impossible had not the author, as he told his audience, methodically made written records of each case on the same principle from the commencement. So anxious was he to be authentic, that he attached to each case the name of the medical man who had original charge of the patient, or, none such existing, he mentioned the name of any medical man who happened to be present at the time of operation.

Sir Henry's five hundred cases represent his entire and unselected work from the commencement of his career up to January 1877—a period of nineteen years. These five hundred cases occurred in four hundred and twenty individuals of twenty years old and upwards, the mean age being sixty-one years and a half; no women are included in the series. Four hundred and twenty-two were cases of lithotripsy with a mortality of one in thirteen, and seventy-eight were cases of lithotomy with a mortality of one in two and three-quarters. The mortality of the whole five hundred cases was one in eight and a half. So low a rate is a very enviable result, and shows how much can be done by a judicious selection of the two operations. And perhaps no fact was more important than this, upon which the author laid stress, viz., that lithotomy and lithotripsy are not to be regarded as antagonistic, but as complementary the one to the other; and, so far from being opposed to each other, that they are really inseparable companions. Sir Henry Thompson has long taught this close relationship. Yet even now, in many minds, the two procedures present conflicting claims; and it is observable that this belief seemed to characterise the remarks of some of the speakers who followed in the discussion. This feeling has to some extent originated in the enthusiasm with which the celebrated father of lithotripsy, Civiale, very naturally advocated the operation. He, indeed, endeavoured almost to supplant lithotomy,

and moreover claimed an immunity from all risk to life for his favourite innovation.

Sir Henry Thompson, at the conclusion of his paper, strongly urged the prudence of restricting the application of lithotomy to narrower limits; and stated, as the result of his experience, that he should rarely attempt to crush a hard stone over one inch and a quarter in its largest diameter, or any stone that could not be crushed by a flat-bladed lithotrite, utterly condemning the use of the fenestrated variety. As lithotomy, confined within due limits, is unquestionably a safer operation than lithotomy, it naturally results that the early detection of stone in the bladder should be the constant aim of the practical surgeon. The author adverted to the occasionally distressing after-results of lithotomy, and agreed with Mr. Cadge that there are some who neither die nor recover, but continue to suffer with painful symptoms. But he thought that these cases would be much more unfrequent, if lithotomy were confined to the limits laid down. And he pointed out that they were cases in which the bladder, ureters, and kidneys were diseased previously to operation, and in which lithotomy was almost necessarily fatal; whilst the occasional introduction of the lithotrite afterwards was the price paid for life. And he inferred, therefore, that, when the patient ultimately succumbed, it was unfair to attribute his death to lithotomy, when it might more fairly be said that the last few years of his life had really been gained by it.

It is worth remarking that this report comprises all the author's cases; and it, therefore, includes his period of inexperience as well as the results of his ripe and mature knowledge. It is, therefore, possible that the surgeons of the future, recognising the proper relations between lithotomy and lithotomy, and the importance of the early detection of calculus, may even obtain a lower rate of mortality than Sir Henry Thompson's result of one in eight and a half; and so contribute still further to render surgery (to use the felicitous language of Sir James Paget) "a most happy profession".

MR. H. SPENCER SMITH, whose retirement by lapse of time from active duties as senior visiting surgeon to St. Mary's we last week mentioned, has been appointed consulting surgeon to that hospital.

WE are informed that Mr. William Gilbert, of whose vigorously written article on the abuse of charity we spoke last week, is a member of our profession, having passed his examination at the College of Surgeons so long ago as 1830.

WE are informed that Mr. Jonathan Hutchinson is likely to succeed Mr. Erasmus Wilson in the Professorship of Dermatology at the Royal College of Surgeons founded by Mr. Wilson, and of which chair Mr. Wilson has fulfilled the duties with characteristic industry and erudition. It is unnecessary to speak of the high claims of Mr. Hutchinson to such a chair. Although dermatology is only one of his many accomplishments in the department of surgery, he holds in that department of practice an authoritative position which is well known and recognised in this and other countries.

WE understand that Mr. Lund of Manchester is likely to be brought forward as a candidate for membership of the Council of the College of Surgeons at the next election, and that his candidature is likely to meet with considerable support at the great London schools. Mr. Lund stands in the first rank of provincial surgeons, and was last year President of the Surgical Section at the Manchester meeting of the British Medical Association, towards the success of which he largely contributed both in a scientific and a social sense.

At a recent meeting of the Hydrophobia and Rabies Committee, satisfactory progress was reported in the tabulation of the cases and the investigation of the literature of the subject. Dr. Gowers reported that he had altogether material of five cases placed at his disposal by professional friends, relating to the investigation of the pathological appearances. Mr. Callender and Dr. J. Burdon Sanderson have had

the opportunity of visiting one patient suffering from hydrophobia, under the charge of Dr. Nicholls at Chelmsford, through the courtesy of that gentleman. We are requested to remind the members of our Association that Dr. J. B. Sanderson, Mr. Callender, and Dr. T. L. Brunton, as members of this Committee, will be glad to receive intimation of any case occurring under the care of members, and would be willing that they should have the opportunity of observing the symptoms and discussing the treatment of any case of hydrophobia. Hitherto, the only case in which this opportunity has been afforded to them is the one above mentioned.

THE breakdown of the Army Medical Department for want of sufficient medical officers for duty is so complete, that at this moment there are not army doctors enough for duty at Woolwich, and the services of local civil practitioners have been put into requisition. What would be the case if war should break out? And is this a satisfactory state of things at a moment when war is considered so probable that extra votes have been taken in preparation for it? The sooner the War Office Committee reports on the causes of the difficulty of recruiting the Army Medical Department the better. Mr. Meldon had a notice on the paper of the House of Commons last week, to call attention to the present state of the department; and it was understood that Dr. Lush, Dr. O'Leary, and the Right Hon. Lyon Playfair were prepared to take part in it. Documents bearing on the subject, and showing what have been the past representations to the Secretary of State at War by our Parliamentary Committee were placed in their hands, and would have furnished some of the materials for debate. But, at the last moment, Mr. Hardy requested that the debate might be postponed until he had received the report of the War Office Committee, of which we have already stated the composition, and which is now hard at work on the subject.

WE are enabled to state that the War Office Committee, which has been appointed to investigate the state of the Medical Branch of the Army, is making extended inquiries as to the causes why so few young surgeons come forward as candidates for commissions in it; and we hear that it is not unlikely that important changes will be made in the terms on which service in the department will be in future regulated. The changes referred to are still, however, under consideration. The desiderata which were last week set forth in this JOURNAL have been forwarded to the Secretary of State at War by the Chairman of the Parliamentary Bills Committee of the British Medical Association, Mr. Ernest Hart, and urged by the Right Hon. Lyon Playfair; and this statement also has been referred to the consideration of the War Office Committee.

MR. HUXLEY has signified his desire to join the Committee to which we last week referred, which has been formed for the purpose of raising an auxiliary fund for a memorial in France in honour of the illustrious physiologist Claude Bernard. The Committee, therefore, now consists of Sir James Paget, Professor Huxley, Dr. J. Burdon Sanderson, Professor Humphry, Mr. Ernest Hart, Mr. Romanes, and Dr. Gerald Yeo (King's College); the latter two gentlemen, being the Secretaries of the Physiological Society, have kindly undertaken, at the request of the Society, also to act as Honorary Secretaries of this Committee.

THE question of the admission of women to the medical licence of the College of Physicians was discussed at the meeting of the Fellows on Monday, and a negative resolution was affirmed by a considerable majority. Dr. T. K. Chambers addresses to us a letter, which will be found in another column, in which he expresses a strong opinion adverse to the decision arrived at. This question seems to have the unhappy privilege of exciting a good deal of strong feeling, and causing the use of rather unusually strong language on every side, whenever it comes under discussion. This, we cannot help thinking, is much to be regretted, as being unlikely to further satisfactory conclusions.

MR. LIEBREICH, who has during the last few years preferred to take his professional vacation in the winter months, in order to be able to enjoy it in a more genial climate has, we understand, requested the authorities at St. Thomas's Hospital to accept his resignation of the office of ophthalmic surgeon and lecturer on ophthalmic surgery in that hospital, because he does not feel justified in withdrawing this vacation-time from the period of instruction of students during the active session of the school. Mr. Liebreich's resignation has been accepted by his colleagues with much regret. He has, however, on the proposition of the Treasurer and staff, by the unanimous decision of the governors, been appointed consulting ophthalmic surgeon to the hospital. In that capacity, he will give to the hospital the benefit of such time as the pressure of professional engagements will allow. The ophthalmic department at St. Thomas's Hospital, created by Mr. Liebreich, with the liberal assistance of the Treasurer and governors and the sympathetic approval of his colleagues, is likely to attract considerable competition, and among the candidates already mentioned are Mr. Nettleship and Mr. Anderson Critchett.

THE subject has been mooted recently of taking steps to procure a suitable celebration of the tercentenary of the anniversary of the birth of Harvey by a banquet, in which the leading members of the medical profession and leading physiologists and others should take part. This proposition, which originated, we believe, with Dr. Michael Foster, and was by him laid before the Physiological Society, has been unofficially discussed and submitted to the leading authorities at the College of Physicians, in connection with which body it is thought such celebration might be most appropriately held. It is suggested, and we believe the suggestion meets with the approval of some of the authorities of the College, that the College of Physicians might appropriately take the leading part in promoting such a celebration of the memory of of the worth of him, of whom the College has most reason to be proud; and that the occasion of the Harveian Oration, which this year will be delivered by no less distinguished a physiologist than Professor Burdon Sanderson, might very properly be chosen for the day of the banquet. The Harveian Oration is delivered on the anniversary of the funeral of Harvey, in virtue of endowments left by him. Harvey directed that his funeral should take place from the College of Physicians, and made some provision in order that the Fellows might dine on the anniversary of that day. His memory kept alive by his great works, has been annually honoured at the College by the Oration, and, until recently, by a banquet, which has of late years been discontinued. The present proposition would involve a celebration which would be so extended as to be of a general character, going beyond the limits of the Fellows, and to which it might be expected that some of the most illustrious persons in the country would be glad to lend the authority of their presence.

WE publish in another column replies from Dr. Markham and Dr. Bond, to the correspondence of Mr. Brown of Northallerton, on the subject of the legal position of the two ladies who are at present members of the Association; and, in the presence of the announcement that a special general meeting is to be held for the purpose of considering the subject, it is unnecessary perhaps that this correspondence should be further continued. We would only remark that the solicitor of the Association will no doubt be able to offer a statement as to the question of law raised by Mr. Brown affecting the actual legal position of the lady members. This question seems to us the less important, as the Association has, under the by-laws, undoubted power of taking a step for any reason satisfactory or itself, as the result of which any member ceases to be a member. If the membership of women be objectionable, that becomes a valid reason for such step. That being the avowed reason, we do not see that it involves any imputation either on the manners of the Association, or on the individuals affected, if this step be taken. It appears to us that the main question is: Is the presence of these two ladies inconvenient and objectionable by reason of

their sex? If it be decided that it is so, and the two ladies are unwilling to relieve the Association voluntarily of that inconvenience, then the taking of steps to provide that they shall cease to be members may follow as a logical consequence, and involves no other imputation on them than that they are women; and that such steps have been taken to prevent their attendance at meetings, where they may cause inconvenience to an Association otherwise wholly composed of men.

A DISTINGUISHED correspondent in the University of Edinburgh writes to us: "It is very pleasing indeed to see the fresh start in life which you have given to Oxford. I can imagine no better place for a medical school." We are glad to be able to add that the attention which we have felt it our duty to call to this question and the vigorous discussion which has taken place in our columns has been already so far productive of good, that Oxford University Commission, which has been sitting for the last few weeks in London, has devoted a large amount of attention to the subject, and has taken evidence bearing upon it from many members of the University, as well as from some outside authorities, of whom a portion are understood to represent the views adopted by Dr. Acland, while others have strenuously advocated the restoration of Oxford as a medical school and the adoption of measures which will enable that University to resume the duties which it owes to medical science and to the medical profession, and which it has so long neglected. Among those who have given evidence in favour of the views which we have advocated are, we believe, Professor Ray Lankester, Dr. Frank Payne, Dr. Risdon Bennett, and Dr. Glynn Whittle; evidence has also been given by Sir James Paget, Sir William Gull, and Dr. Andrew (St. Bartholomew's). It is much to be desired that this evidence, on a subject of such great importance to the University and the future of medical science in this country, should be published. It is already printed, but we believe there may be some difficulty in obtaining publication of it.

WE would direct attention to the letter of Mr. Hatherly, the honorary secretary to the Nottingham Branch of the Medical Defence Association, with reference to the appeal made by Mr. Stanger in our issue of the 9th inst. for pecuniary assistance in carrying on the case of the plaintiffs in the appeal of the Apothecaries' Company v. Shepperly. This case will be one of the highest importance not only for the interests of the profession but also, we believe, for the safety of the public. Every one has seen, in either hospital practice or general practice, the immense amount of mischief done by the existing abuse under which chemists make hasty diagnoses across the counter, or, upon the report of some ignorant relative, undertake to prescribe on cases which, apparently simple in the outset, are often in subsequent development most serious and frequently fatal. We reported a case last week in which such counter-prescribing involved the diagnosis of chicken-pox as small-pox, and set up a centre of contagion dangerous to a whole neighbourhood. The practice, however, is so common, and the instances of evil results are so numerous, within the knowledge of almost every medical man, that it is hardly necessary here to emphasise or discriminate them. What we wish to point out once more is that, in the case of the Apothecaries' Company v. Shepperly, a small local society in Nottingham is virtually fighting a cause which is that of the public and of the profession against the whole weight of a powerful society of chemists, in putting down that dangerous and, we believe, illegal practice. We will, therefore, again express the hope that this appeal will meet with considerable support from medical men; and we do not doubt that this will be the case if our readers sufficiently consider how large are the issues involved in the battle which Mr. Stanger, Mr. Hatherly, and their associates, are fighting.

#### THE EARL OF HARDWICKE.

THE Master of the Queen's Buckhounds fell from his horse in the hunting-field on Tuesday last, and is suffering from concussion of the brain and spinal cord. He was at once brought to his house in Arlington Street, and on Wednesday was reported to be doing well.

## PENAL SERVITUDE COMMISSION.

THE Royal Commissioners recently appointed have already begun their inquiries into the working of the Penal Servitude Acts. Among the many questions which must come before them, will be the all-important one whether the moral effect of our present system of indiscriminate association does not press too heavily on the better educated class of prisoners, such as political offenders and those who are not habituated to crime. Another subject will, no doubt, be the association of habitual criminals: whether it does not tend to the increase of crime, and fail to satisfy the penal and reformatory objects aimed at by the dread sentence of the law. Their decisions on both these subjects will be interesting. We are glad to see they have secured the able services of Dr. Greenhow to assist them on the many medical questions which must claim their consideration. Last week, we called attention to the anomalous duties and exceptional services rendered by prison surgeons to their thankless patients, and the small recompense they receive. We hope the facts and medical statistics laid before the Commissioners will satisfy them as to the work done, and have the effect of procuring for the medical officers a more just recognition of their claims. The redundancy of the executive, as compared with the medical department, at the large invalid and lunatic establishment at Woking, cannot fail to attract the attention of the Commission, and raise the question whether it is not advisable that such establishments should be under the control of a medical superintendent. We are of opinion that the safe custody of invalid prisoners, and all the discipline desirable or possible for them, could be more justly secured by the adoption of this reform. With a staff as constituted at present, there must of necessity be sudden difficulties arising out of the opposing efforts of the executive authorities to enforce discipline, and of the doctors to protect infirmity.

## DENTAL PRACTITIONERS' BILL.

WE are very glad to be able to agree in the views expressed by Mr. Coleman, the President of the Odontological Society, and Mr. Sibley, President of the Metropolitan Counties Branch, as to the course which is to be taken in reference to the Dental Practitioners' Bill. That Bill passed its second reading on Friday last without further opposition. The Chairman of the Parliamentary Bills Committee of our Association felt justified in withdrawing further opposition upon the pledge which has been given to Dr. Cameron, who has acted for the Committee in this matter, that the obnoxious clauses will be remodelled in a form to meet the views expressed by the Committee at their last meeting, and in accordance with the resolutions they passed. Sir John Lubbock has undertaken at once to reprint the Bill in its amended form; and in that form we believe that the Bill, subject probably to some further amendments of subsequent clauses in Committee, will be likely to meet the obviously just requirements of a satisfactory registration of dentists without infringing any privileges of the medical profession; and, under such circumstances, we agree with our correspondents that this Bill will deserve support. It will, however, be seen that what we intimated would take place has occurred; the Government Medical Acts Amendment Bill includes a provision for the registration of dentists. Sir John Lubbock has, in any case, undertaken not to proceed with his Bill until the General Medical Council have had time to consider it. Under these circumstances, we are inclined to believe that Sir John Lubbock's Bill will not ultimately become law, but, when the principles which it embodies have been approved, the Bill itself will give way to the Government measure having the same objects.

## THE SAMARITAN HOSPITAL.

THE annual meeting of the Governors of the Samaritan Free Hospital was held in the board-room of that institution on Tuesday, March 19th, Sir Charles Rowley, Vice-President, in the chair. The secretary, Mr. George Scudamore, read the balance-sheet, from which it was shown that the total income for the year 1877 was £8,552 12s. 6d., and the expenditure £8,472 17s. 4d.; leaving a balance of £79 15s. 2d. The

results of the past year, both financially and from a medical point of view, were highly satisfactory. Sir Henry Montgomery, in proposing a vote of thanks to Mr. Spencer Wells, referred to his great success, and regretted that he was obliged to withdraw from the active surgical work of the hospital. Mr. Wells, in acknowledging the vote of thanks, bore testimony to the increasing success in the treatment of ovarian disease, attributing the good results to the introduction of the antiseptic treatment. Votes of thanks to the lay and medical officers and to the chairman brought these interesting proceedings to a close.

## THE HARVEY TRICENTENARY MEMORIAL.

WE published last week an appeal from Mr. Eastes, the secretary of the Harvey Tricentenary Fund, on behalf of a Committee which has already raised £800 towards the cost of a statue to Harvey, and which desires to raise nearly as much more in order to complete the object in view. This subscription has dragged over several years, and it is some reproach to the country that it has not been more speedily filled up. It is now proposed, in virtue of a resolution passed on the motion of Sir Thomas Watson and Sir George Burrows, to make a special appeal not only to the profession at large, but also to the British Medical Association and its Branches and to all the great corporate bodies and universities in their collective capacities, to assist by contributions to the fund, and by taking measures to promote the subscription. We trust that this appeal may be successful, and that the national reproach, that no adequate memorial to Harvey exists in a country where statues abound to the shedders of blood, may be speedily wiped away.

## THE CHARING CROSS HOSPITAL.

A CORRESPONDENT writes to us in reference to the recent proceedings at the Charing Cross Hospital:—"The rule of the Hospital is clear enough, and is to the following effect: 'Every physician and surgeon of the Hospital is to retire from his office on the completion of the sixtieth year of his age, when he may become Consulting Physician or Consulting Surgeon, and be also eligible to be elected an Honorary Life Governor and to serve as a member of the Council. This rule is to be prospective only, and not retrospective (1868).' Now when this rule was generally accepted by the staff, and fully discussed and passed, Mr. Hird was and had been only a short time Assistant-Surgeon to the Hospital. Five years ago, Mr. Hird attained his sixtieth year, and then it was deemed advisable to notify the fact to the Council and ask for a further extension of his term of office, in consideration that he had *only for a few years been surgeon*. This was granted, and just before the last annual meeting this additional period expired." The facts, therefore, appear to be exactly as we stated them; and the further prolongation of office seems to be a second infraction of a very useful rule, and one which needs to be noticed not only on its own account but as forming, possibly, a bad precedent.

## THE TELEPHONE AS AN ELECTRIC REAGENT.

AT the meeting of the Paris Société de Biologie, on March 2nd, M. Darsonval said that, up to the present time, the most sensitive electric reagent was the nerve-tissue. The telephone, however, is an infinitely more sensitive reagent; he proves this by first placing an induced current in contact with the sciatic nerve of a frog, and showing that this current, when it can no longer excite the nerve, still makes the telephone vibrate.

## THE DEPOPULATION OF POLYNESIA.

A PAPER by M. Bordier, published in the *Revue d'Anthropologie*, states that Polynesia is becoming depopulated. The direct agent of this state of things is pulmonary phthisis. At Tahiti, which has the finest climate in the world, every one coughs, every one has bronchitis, and eight out of ten are tuberculous. In the Gambier Archipelago, the population has, in thirty years, diminished from 1,600 to 150; at Nonka Iliva, the aborigines have, in twenty-six years, decreased from 6,000 to 1,000. Captain Cook, in 1774, estimated the entire popula-

tion of the Hawaiian Islands at 200,000; in 1800, but 150,000 survived. They have now diminished to 55,000; and, during the last six years, there have been 2,671 births against 4,167 deaths. It would seem that wherever the European has passed he has sown the seeds of death for these unfortunate Polynesians. Darwin has already long since pointed out that the departure of an European vessel is always followed, even amongst populations isolated up to that time, by the breaking out of infectious diseases, without characteristics which we should term classic, and which bear hardly on the aborigines only.

#### INQUESTS WITHOUT INQUIRY.

SOME coroners appear to think that their particular function is to make as happy a guess as possible at the causes of death, and to veil their ignorance of details under the general terms of an open verdict. It is very difficult on any other hypothesis to understand the reason which induced the coroner, in the case of the recent mysterious deaths at Ware, obstinately to refuse to order a *post mortem* examination, in the absence of which none other than a distant guess was possible as to the cause of death. We have had recently to record and to regret a similar course upon the part of other coroners. No course could well be devised better calculated to defeat the object of the inquiry.

#### SURGICAL AID SOCIETY.

THE Secretary of this Society informs us that, since the last general meeting of the subscribers, the Committee have given him the power, in any case in which it may appear necessary, to order the appliance (upon the certificate of the surgeon) at once, without waiting for additional letters; and, in addition, they have every month before them a list of all cases requiring a number of letters, and vote the remainder to such cases as they may deem deserving.

#### THE METROPOLITAN COUNTIES BRANCH AND THE CHARITY ORGANISATION SOCIETY.

AT the meeting of the Council of the Charity Organisation Society held on Monday, March 4th, Sir Charles Trevelyan called attention to the recent meeting of the Metropolitan Counties Branch to hear Mr. Holmes's paper on provident dispensaries, and also called attention to the resolution of Council of March 15th, 1874: "That, as the conversion of the existing free dispensaries into provident dispensaries, and the establishment of new provident dispensaries where required, is an indispensable preliminary to the reform of the system of medical relief, the local committees of this Society be recommended to exert themselves for the promotion of this object in their respective districts." He submitted to the Council that the time had arrived when an united and persistent effort should be made by all the committees of the Society, acting in concert with the members of the medical profession and the governing bodies of the hospitals and dispensaries, to place medical relief on a footing which would at once secure the efficient medical treatment of the working classes and promote the formation of provident self-respecting habits. An adjourned meeting of the Metropolitan Counties Branch, to conclude the discussion on Mr. Holmes's paper, will be held on Wednesday next, at 8 P.M., at the rooms of the Medical Society of London.

### SCOTLAND.

THE trial of M. Chantrelle, a teacher of French in Edinburgh, for the murder of his wife, is expected to come on soon. The evidence, which is of a voluminous and intricate character, will render the trial one of unusual interest to the medical jurist.

DR. J. B. RUSSELL, the Medical Officer for Glasgow, has issued in a pamphlet form his report on the outbreak of enteric fever in the West End of Glasgow and Hillhead, just submitted to the Health Committee of the Glasgow Town Council. From the figures supplied by Dr. Russell, it appears that there were one hundred and sixty-six cases of fever traceable more or less to poisoned milk, but out of this number only sixteen proved fatal.

THE epidemic of measles, which has been so severe in Edinburgh for some weeks past, is rapidly subsiding. Last week, only seven deaths from this disease were registered. There were three deaths from whooping-cough, and none from scarlet fever, diphtheria, or small-pox. The death-rate for the week fell from 30 to 22 per 1,000.

AN extensive fire took place on Wednesday, March 13th, at the premises in Nicholson Street belonging to the Edinburgh Blind Asylum. In the part of the premises which were burned were the rooms occupied by a large number of the blind and some "seeing" assistants at work at various branches of industry, including brush-making, pailasse-making, and similar employments. All the men were got out without injury; but a quantity of valuable property was destroyed. The loss is estimated at £10,000, which is covered by insurance. Employment was given in these workshops to about one hundred and sixty people, of whom one hundred and forty were blind.

AT Lochgelly last week, Sheriff Bell heard evidence relative to the introduction of a water-supply from Lochernie. The evidence showed that such a supply was eminently needed. The cost of the works was estimated at £6,800; and it was stated that the supply would be twenty thousand gallons per day, which would give twenty gallons to each inhabitant. It was stated that the water had a yellowish tinge, but that Lochernie was the only available source. Dr. Macadam had reported that it was quite suitable for domestic purposes. The sheriff thought the colour of the water a somewhat serious objection, and intimated that he would report the state of matters to the Secretary of State. The scheme was opposed by the Right Hon. W. P. Adam of Blairadam and Mr. Constable.

#### THE GLASGOW OPHTHALMIC INSTITUTION.

THE Glasgow Ophthalmic Institution has just published its ninth annual report. 3,663 cases have been treated during the past year, of whom 355 were taken into the hospital for treatment, the remainder being out-patients. The average period of the patients' residence in hospital was 20.10 days; of the cases treated, 3,504 were dismissed cured, 105 relieved, and 54 dismissed as incurable. The number of in-door patients was much restricted by want of sufficient accommodation. It was necessary to enlarge the house, and, in order to do so, the patron, the Earl of Stair, had agreed to give a sum of £200, provided nine other subscribers of a like sum could be found. Seven gentlemen had since come forward. The treasurer's report showed a slight excess of expenditure over income.

#### UNIVERSITY OF GLASGOW.

A PRIVATE meeting of the members of the General Council of Glasgow University, "who are of opinion that the nomination of a Chancellor for the University should be made on academic grounds", was held on Monday last, under the presidency of Professor Dickson. There was considerable diversity of opinion as to what course should be followed, but ultimately the Duke of Buccleuch and Sir Joseph Dalton Hooker were suggested for the vacant office. A vote was taken, when fifty voted for the Duke of Buccleuch and thirty-one for Sir Joseph Hooker. Some of those present more than hinted that they did not look upon the result of the vote as binding. Ultimately, a committee was appointed with the view of bringing about an arrangement so that the Duke might be returned without a contest.

### IRELAND.

#### QUEEN'S UNIVERSITY.

AT a recent meeting of the Senate of this University, the following examiners were appointed in the place of those who retired by rotation. T. W. Grimsbow, M.D., Examiner in Medicine; William Mac Cormac, Esq., Examiner in Surgery; R. J. Kinkead, M.D., Professor of Obstetric Medicine, Queen's College, Galway, Examiner in Midwifery; J. W. Moore, M.D., Examiner in Materia Medica; and J. F. Hodges,

M.D., Professor of Medical Jurisprudence, Queen's College, Belfast, Examiner in Medical Jurisprudence. There are now, accordingly, a physician and a surgeon of two London hospitals on the Board of Examiners of the Queen's University. Dr. Bastian, of University College Hospital, was appointed an Examiner in Medicine at the last election. Mr. Mac Cormac, of St. Thomas's Hospital, who is now his colleague, resigned the seat he occupied on the Senate of the University, of which he is a distinguished graduate, in order to become a candidate for the examinership to which he has been appointed. The examiners generally hold office for two years, and we understand that there is a probability of there being another election to these posts in July.

#### SMALL-POX EPIDEMIC IN DUBLIN.

ONE hundred and eighteen cases were reported as having been under treatment in the Dublin hospitals at the end of last week. The Committee appointed by the South Dublin Union to consider the best means of providing increased hospital accommodation for small-pox patients have recommended the guardians to rent forthwith, for a period of not less than three years, the sheds and grounds at Kilmainham, which were used as a small-pox hospital during the epidemic of 1871-73. They also recommend that arrangements be made for making the department available at the earliest moment for the reception of patients, and that a medical man be appointed to take charge of the premises and act as resident medical officer.

#### CORK STREET FEVER HOSPITAL.

THE annual report of this valuable institution for the year ending March 31st, 1877, has been recently issued. The admissions during the year were 666, against 653 in the previous year, showing an increase of 13 patients. The total number of cases treated during the year, including the balance from the previous year, was 718. Of these, 67 died, against a mortality of 56 in the year 1875-76; the general rate of mortality being 8.57 for 1875-76, and 10.06 for the past year. In the able medical report which the late senior, and present consulting, physician to the hospital, Dr. Grimshaw, also furnishes, we are informed that of the 67 deaths that occurred during the year, 21, or nearly one-third, were admitted in a condition practically beyond the aid of medical treatment. The high rate of mortality may thus be accounted for to a great extent; and a table is given analysing these 21 deaths, which affords strong evidence of the effect similar cases have upon hospital statistics. It should be noticed that one-third of the deaths detailed in the table alluded to were cases of bronchitis admitted in a moribund condition. Such cases are not suited for admission into a fever hospital; but as a matter of humanity, it was necessary, in the present instance, to take them in and care for them. If all the cases admitted in a state past the hope of recovery be excluded, Dr. Grimshaw states that 7.14 per cent. would represent the mortality among those cases coming fairly under treatment. As pointing to a very low state of vitality among the poor of Dublin, attention is called to the unpleasant fact that the percentage rate of mortality from such common and constantly prevailing zymotics as typhus and enteric fevers has increased during the past few years. Valuable tables, showing for quinquennial and septennial periods the monthly and quarterly admissions, etc., of the different forms of continued fever, accompany Dr. Grimshaw's report. The mortality from enteric fever was higher during the year which the report covers than in any year since regular statistical tables have been kept in the hospital. This increased fatality of fever may, it is believed, be in a great measure attributed to the increase of the vice of intemperance. An interesting sketch of the inception of the present epidemic of small-pox in Dublin concludes the report. The disease appears to have been introduced from Manchester in August 1876, and to have slowly spread in the usual manner. Dr. Grimshaw, like every other "well educated sanitarian", considers the complete destruction of the clothing of small-pox patients to be the only certain, effectual, and economic method of checking the spread of this formidable malady. He shows that the destruction of the clothing of one

person infected by small-pox, as provided for by the Public Health Act, the owner being compensated at the public expense, would be a saving to the community if it only prevented the occurrence of one case. We can fully endorse a statement the Board of Superintendence of Dublin Hospitals made in reference to former reports in the case of the present, viz., that "the reports of this hospital are drawn up with great care, and contain valuable information". We should not omit to mention two important meteorological tables, drawn up by Dr. J. W. Moore, one of the physicians to the hospital, which are included in the report.

#### SCIENTIFIC LECTURES.

THE last of this season's series of scientific lectures at the King and Queen's College of Physicians was delivered on Monday by Dr. Grimshaw, it being his second lecture, on Contagion and its Relation to the Prevention and Cure of Zymotic Diseases. The first portion of the lecture was devoted to the consideration of the contagion of specific diseases. The relation of the theories of spontaneous generation and contagium vivum, and the development of contagious zymotics were considered. The lecturer adopted the latter theory of defining the term as a "seed of disease". The nature of the operation of contagium and septic infection was contrasted, and the views of Dr. Beale as to the part that bioplasm plays in the propagation of contagion were considered. The various proofs of the particulate nature of contagion were referred to, and adopted by the lecturer. The grounds for believing in the living and vegetable nature of contagion were considered, and then the various organisms which had been met with by different observers in vaccinia, variola, sheep-pox, splenic fever, and relapsing fever were described, and diagrams exhibited illustrative of the lecturer's remarks. The second portion of the lecture was occupied by the application of the information we possess to the prevention and cure of disease. The various means of preventing septic infection were considered, and tables of antiseptics and their relative powers exhibited. It was pointed out how the action of many of these antiseptics might be interfered with. The lecturer showed that, while we did not possess any antidote to the septic poison, yet we had many means of preventing its production, by the destruction of bacteria. The lecturer viewed the question of the prevention and cure of contagious fever from the following points of view. *a.* The modification of the nature of contagion (as by vaccination). *b.* The destruction of contagion—1. Without the body, by the application of disinfectants; 2. Within the body, by the use of salicylic acid, quinine, etc. *c.* The counteracting the effects of contagion. In considering the last subject, the lecturer dwelt upon some points in the treatment of fevers which he considered important, and pointed out what he believed to be errors in some forms of antipyretic treatment.

#### SEWERAGE OF DUBLIN.

THE state of the sewers in this city, taken in connection with the high death-rate, has been lately very forcibly brought before the public mind. At present, many streets are left without any provision for the timely removal of refuse. Not only this, but in some of the best districts of the city in which main sewers do exist, the inhabitants of excellent houses are in many cases so apathetic that they either have not connecting pipe-drains with the main sewer, or else have permitted these connections, in cases where they exist, to become so defective that their houses become noisome and pestilent from the entrance into them of foul sewer gases. Out of sixty-eight houses surrounding one of the largest squares in Dublin, only seventeen availed themselves of a recent opportunity of the main sewer being opened to make connecting pipe-drains. We are glad to see that the Chairman of the Public Health Committee of the Corporation, Mr. E. D. Gray, M.P., has taken the matter up; and that he carried a resolution at the last meeting of the Corporation by which steps will be taken forthwith to have the entire sewerage of the city completed in the least possible time. This will take five or six years more to do, and will cost about £30,000.

## BILL TO AMEND THE MEDICAL ACT (1858).

BE it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows :

*Preliminary.*—1. This Act shall be construed as one with the Medical Act (1858), and the Acts amending the same, mentioned in the first schedule to this Act so far as they are unrepealed, and those Acts and this Act may be cited together as *The Medical Acts, 1858 to 1878*; and each of those Acts may be cited by the short title in the said schedule mentioned, and this Act may be cited as *The Medical Act, 1878*.

II. This Act shall come into operation on the first day of January, one thousand eight hundred and seventy-nine, which day is in the Act referred to as the commencement of this Act.

*Registration.*—III. After the commencement of this Act, the medical registrar shall not register a person in the *Medical Register* unless either such person holds a double qualification within the meaning of this Act, obtained after examination in the United Kingdom, or unless such person is a colonial or foreign practitioner entitled under this Act to be registered without examination in the United Kingdom.

For the purposes of this Act a double qualification means a qualification to practise both medicine and surgery, and shall be either—(a) a medical diploma granted by one of the medical authorities to a person who has obtained from a medical board under this Act a qualifying certificate, that is to say, a certificate that he has shown himself by examination to be qualified under this Act to practise both medicine and surgery; or (b) two of the qualifications described in Schedule A to the Medical Act, 1858, as amended by subsequent Act, of which one is a qualification granted after examination in respect of proficiency in medicine, and the other is a qualification granted after examination in respect of proficiency in surgery;

Provided that nothing in this section shall extend to a person who at the commencement of this Act is registered or entitled to be registered in the *Medical Register*, or prevent the restoration to the *Medical Register* of the name of any person who had been registered therein before such commencement, and whose name might, but for this section, have been restored to the *Register*.

IV. Where a person, who either has obtained after the commencement of this Act a double qualification within the meaning of this Act, or has obtained before the commencement of this Act, a qualification to be registered under the Medical Act, 1858, produces or sends to the medical registrar the document conferring or evidencing such qualification, with a statement of his name and address, and the other particulars, if any, required for registration, and pays the registration fee, he shall be registered in the *Medical Register*.

V. Where a person, who either is not domiciled in the United Kingdom, or has practised medicine or surgery or a branch of medicine or surgery for more than ten years elsewhere than in the United Kingdom, shows that he holds some recognised medical diploma or diplomas (as hereinafter defined) granted in a British possession, and that he is of good character, such person shall upon payment of the registration-fee be entitled, without examination in the United Kingdom, to be registered as a colonial practitioner in the *Medical Register*.

VI. Where a person, who is not a British subject, or who has practised medicine or surgery or a branch of medicine or surgery for more than ten years elsewhere than in the United Kingdom, shows that he obtained some recognised medical diploma or diplomas (as hereinafter defined) granted in a foreign country, and that he is of good character, and either continues to hold such diploma or diplomas, or has not been deprived thereof for any cause which disqualifies him for being registered under this Act, such person shall upon payment of the registration-fee be entitled, without examination in the United Kingdom, to be registered as a foreign practitioner in the *Medical Register*.

VII. The medical diploma or diplomas granted in a British possession or in a foreign country, which are to be deemed recognised medical diploma or diplomas for the purposes of this Act, shall be such medical diploma or diplomas as may be recognised for the time being by the General Medical Council as entitling the holder thereof to practise medicine and surgery in such possession or country, and as representing at the time of the grant thereof a degree of knowledge, as tested by examination, equal to or greater than that which at the same time was required to obtain in the United Kingdom such qualification as entitles the holder to be registered in the *Medical Register*.

If a person is refused registration as a colonial practitioner or as a foreign practitioner, the medical registrar shall, if required by him, state in writing the reason for such refusal, and if such reason be that the medical diploma or diplomas held or obtained by him is or are not such recognised medical diploma or diplomas as above defined, such person may appeal to the Privy Council, and the Privy Council, after hearing the General Medical Council, may dismiss the appeal or may order the General Medical Council to recognise such medical diploma or diplomas, or any of them, and such order shall be duly obeyed.

VIII. Where the General Medical Council are satisfied of the eminent professional acquirements and character of any person, who for more than ten years has been practising medicine or surgery or any branch of medicine or surgery in any foreign country or elsewhere out of the United Kingdom, they may if they think fit, by a special order, direct such person to be registered in the *Medical Register* as a foreign or colonial practitioner, as the case may require, and such person, upon payment of the registration-fee, shall without examination in the United Kingdom be registered accordingly as a foreign or colonial practitioner in the *Medical Register*.

IX. 1. The *Medical Register* under the Medical Act, 1858, shall—(a) Contain in one alphabetical list all persons who are either registered at the commencement of this Act, or being entitled at the commencement of this Act to be registered are subsequently registered, and all persons who are registered in respect of a qualification obtained after the commencement of this Act in the United Kingdom; and (b) Contain in a separate alphabetical list all such colonial practitioners as are registered in pursuance of this Act; and (c) Contain in a separate alphabetical list all such foreign practitioners as are registered in pursuance of this Act.

2. The *Medical Register* shall contain the said lists made out alphabetically according to the surnames, and shall state the full names and addresses of the registered persons, the description and date of the qualifications in respect of which they are registered, and, subject to the provisions of this Act, shall contain such particulars and be in such form as the General Medical Council from time to time direct.

3. The registration-fee shall be such fee, not exceeding five pounds, as the General Medical Council from time to time fix.

4. The General Medical Council shall cause a correct copy of the *Medical Register* to be from time to time and at least once a year printed under their direction, and published and sold; and such copy shall be deemed to be the copy of the *Medical Register* referred to in section twenty-seven of the Medical Act, 1858.

5. The *Medical Register* shall be deemed to be in proper custody when in the custody of the medical registrar, and shall be of such a public nature as to be admissible as evidence of all matters therein on its mere production from that custody.

6. Subject to the orders from time to time made by the General Medical Council, the medical registrar shall inform the local registrar of every entry or alteration in the *Medical Register* which requires to be made in the local register, and the local registrar shall inform the medical registrar of any entry or alteration appearing to him to be required in the *Medical Register*.

7. The General Medical Council may, if they think fit, from time to time make, and when made, revoke and vary orders for the registration in (on payment of the fee fixed by the orders) and the removal from the *Medical Register*, of any diplomas which appear to the Council to be granted after examination by any of the medical authorities in respect of a higher degree of knowledge than is required to obtain such qualification as entitles the holder to be registered in the *Medical Register*, and orders for carrying into effect the provisions of the Medical Acts 1858 to 1878 with respect to the registers; and every registrar shall in all respects, in the execution of his discretion and duty in relation to any register, conform to such orders, and to any special directions given by the General Medical Council.

X. 1. The medical registrar shall from time to time insert in the *Medical Register* any alteration which may come to his knowledge in the name or address of any person registered.

2. The medical registrar shall erase from the *Medical Register* the name of every deceased person.

3. The medical registrar may erase from the *Medical Register* the name of a person who has ceased to practise, but not (save as hereinafter provided) without the consent of that person; and the medical registrar may send by post to a person registered in the *Medical Register* a notice inquiring whether or not he has ceased to practise; and if the registrar does not, within three months after sending the notice, receive any answer thereto from the said person, he may, within fourteen days after the expiration of the three months, send him by post in a registered letter another notice, referring to the first notice, and stating that no answer thereto has been received by the registrar; and if the

registrar, either before the second notice is sent receives the first notice back from the dead-letter office of the Postmaster-General, or receives the second notice back from that office, or does not within three months after sending the second notice receive any answer thereto from the said person, that person shall, for the purpose of the present section, be deemed to have ceased to practise, and his name may be erased accordingly.

4. In the execution of his duties, the registrar shall act on such evidence as in each case appears sufficient.

XI. The General Medical Council shall cause to be erased from the *Medical Register* any entry which has been incorrectly or fraudulently made.

Where a person registered in the *Medical Register* has, either before or after the commencement of this Act, and either before or after he is so registered, been convicted either in Her Majesty's dominions or elsewhere of an offence which, if committed in England, would be a felony or misdemeanour, or been guilty of any infamous or disgraceful conduct in a professional respect, that person shall be liable to have his name erased from the *Register*.

The General Medical Council may, and upon the application of any of the medical authorities shall, cause inquiry to be made into the case of a person alleged to be liable to have his name erased under this section; and, on proof of such conviction, or of such infamous or disgraceful conduct, shall cause the name of such person to be erased from the *Register*.

Provided that the name of a person shall not be erased under this section on account of his adopting or refraining from adopting the practice of any particular theory of medicine or surgery, nor on account of a conviction for a political offence out of Her Majesty's dominions, nor on account of a conviction for an offence which, though within the provisions of this section, does not, either from the trivial nature of the offence, or from the circumstances under which it was committed, disqualify a person for practising medicine and surgery.

XII. Where the General Medical Council direct the erasure from the *Medical Register* of the name of any person, or of any other entry, the name of that person, or that entry shall not be again entered in the *Register*, except by direction of the General Medical Council, or by order of a court of competent jurisdiction.

If the General Medical Council think fit in any case, they may direct the medical registrar to restore to the *Medical Register* any name or entry erased therefrom (either before or after the commencement of this Act), either without fee or on payment of such fee, not exceeding the registration fee, as the General Medical Council from time to time fix, and the registrar shall restore the same accordingly.

The name of any person erased (either before or after the commencement of this Act) from the *Medical Register*, at the request of such person, or with his consent, shall, unless it might, if not so erased, have been erased by order of the General Medical Council, be restored to the *Register* on his application, on payment of such fee not exceeding the registration fee as the General Medical Council from time to time fix.

XIII. The General Medical Council shall exercise the powers of erasing from, and of restoring to, the *Medical Register* the name of a person or an entry by a Committee of their own body, not exceeding five in number, of whom the quorum shall be not less than three.

The General Medical Council shall from time to time appoint and shall always maintain a Committee for the purposes of this section, and, subject to the provisions of this section, may from time to time determine the constitution, and the number and tenure of office of the members, of the Committee.

The Committee from time to time shall meet for the despatch of business; and, subject to the provisions of this section and of any regulations from time to time made by the General Medical Council, may regulate the summoning notice, place, management, and adjournment of such meetings, the appointment of a chairman, the mode of deciding questions, and generally the transaction and management of business, including the quorum, and if there is a quorum the Committee may act, notwithstanding any vacancy in their body. In the case of any vacancy, the Committee may appoint a member of the General Medical Council to fill the vacancy until the next meeting of that Council.

A Committee under this section shall exercise in the name of the General Medical Council all powers vested in that Council of or incidental to the erasing from or restoring to the *Medical Register* the name of a person or an entry, and for the purpose of the exercise of such powers may, at the expense of the Council, employ such legal or other assessor or assistants, and institute and defend such legal proceedings as the Committee think necessary or proper.

*Examination Rules.*—XIV. Whereas, under the Medical Act, 1858,

the General Medical Council has certain duties as regards the superintendence of the examinations to be gone through in order to obtain qualifications for registration from the medical authorities, and it is expedient to give to that Council further powers for the performance of those duties, in order that the double qualification may be granted on the like terms in all cases. Be it therefore enacted as follows:

1. The General Medical Council shall from time to time frame, and when framed may revoke, alter, and add to rules (in this Act referred to as examination rules), for regulating the examinations of persons desiring to obtain a double qualification within the meaning of this Act, and determining the subjects thereof and the standard for passing and the method of conducting the same, and providing for the superintendence thereof by such Council.

2. The examination rules shall not require a candidate to adopt or refrain from adopting the practice of any particular theory of medicine or surgery.

3. The examination rules shall determine the conditions of admission of candidates to the examinations, and shall provide for the admission thereto on special terms of persons who have obtained medical diplomas or studied in any British possession or foreign country, or have passed other examinations.

4. The examination rules shall provide for the admission of women to the examinations, provided that—(a) they shall not compel any medical authority, who at the passing of this Act have not any obligation to grant and have not granted a medical diploma to women, to admit a woman to examination for a qualification granted by that authority; and (b) they shall not compel a woman, in order to obtain such qualification as will entitle her to be registered in the *Medical Register*, to pass, if she object so to do, the same examination as men, without any distinction on the ground of sex.

5. The examination rules, and the revocation or alteration thereof, so far as they relate to the admission of candidates, shall be submitted to the Privy Council for confirmation; and the Privy Council, after giving to the medical authorities an opportunity for objecting, and after considering any objection made, may, if they think fit, by order confirm such rules, revocation, or alteration, either without modification, or with any modifications therein of which notice has been given to the medical authorities and General Medical Council.

6. If any medical authority feel aggrieved by any of the examination rules, or if any authority or persons feel aggrieved by the failure of those rules to recognise any particular examination or any particular place or course of study, such authority or persons may appeal to the Privy Council; and the Privy Council, after communication with the General Medical Council, may make such order in the matter as they think just, which order shall be duly observed.

7. If the Privy Council refuse to confirm any examination rules, the General Medical Council shall, as soon as may be, propose to the Privy Council new rules.

8. If it appears to the General Medical Council that any medical authority fail to comply with the examination rules, they may represent the same to the Privy Council; and, upon such representation, sections twenty-one and twenty-two of the Medical Act (1858) shall, so far as circumstances admit, apply as if the representation were a representation within the meaning of those sections.

*Board for Medical Examinations.*—XV. Whereas, by section nineteen of the Medical Act (1858), any two or more of the medical authorities are authorised, with the sanction of the General Medical Council, to unite in conducting the examinations required for qualifications to be registered under that Act, and it is expedient to make further provision with respect to such union. Be it therefore enacted as follows:

Any two or more of the medical authorities may agree to frame, with the sanction of the General Medical Council, a scheme for appointing persons to examine on behalf of all the authorities who are parties to the scheme persons who desire to practise medicine and surgery, and such scheme when confirmed, as hereinafter mentioned, shall, so far as is consistent with the other provisions of this Act, have full effect, and the persons in whom the nomination of the examiners is vested by the scheme are in this Act referred to as a medical board.

Where any two or more of the medical authorities have before the passing of this Act agreed, with the sanction of the General Medical Council and the approval of the Privy Council, upon any such scheme as aforesaid, that scheme is hereby confirmed and shall come into operation at the commencement of this Act without any further confirmation.

In any other case the General Medical Council may submit the scheme as sanctioned by them to the Privy Council for confirmation, and the Privy Council, after considering any objection made, may, if they think fit, by order confirm the scheme, either without modifica-

tion, or with any modification therein made after communication with the medical authorities concerned and the General Medical Council.

Such scheme when confirmed shall come into operation on the date of the order confirming it, or any later date mentioned in the order.

XVI. A medical board under a scheme shall from time to time hold examinations according to the scheme, and subject thereto in such manner and at such places and times as the board think expedient.

A medical board shall comply with the examination rules under this Act as well as with the scheme, and shall have the same opportunity as a medical authority of objecting to any examination rules, and of applying to the Privy Council respecting them.

The General Medical Council and the Privy Council respectively shall have the same power and authority in relation to a medical board under a scheme, and to the examinations held by them, as they have under the Medical Act, 1858, in relation to the medical authorities parties to that scheme and sections eighteen to twenty-three, both inclusive, of the Medical Act, 1858, so far as unrepealed shall apply as if there were herein re-enacted and in terms made applicable to the board as well as to the said medical authorities, and any order made thereunder shall apply as well to the said authorities as to the board; and if the General Medical Council represent to the Privy Council that a medical board fail to comply with the scheme or examination rules, the above-named sections shall, so far as circumstances admit, apply as if the representation were a representation within the meaning of those sections.

XVII. A medical board under any scheme, as soon as may be after the close of each examination held by them for qualifying certificates, shall with respect to each of the persons who have passed such examination, and paid the required fees, certify that he has shown by examination that he is qualified under this Act to practise both medicine and surgery, and shall do so by sending to the medical registrar and to every medical authority party to such a scheme, a list, certified by the board, of the names and addresses of all such persons.

Every person named in such list shall be deemed to have obtained a qualifying certificate under this Act from such board, and shall be entitled on application to receive from any medical corporation being a party to the scheme, one of the medical diplomas which that corporation have for the time being power to grant, but shall be entitled to receive from each medical corporation such one only of those diplomas as that corporation from time to time provide, and shall not, except so far as the medical corporation otherwise in their discretion provide, be entitled to any share in the government, management, or proceedings of that corporation, or to any rights or privileges in connection with that corporation.

If a medical authority certify to the medical registrar the names and addresses of the persons who, having obtained qualifying certificates under this Act from a medical board, have received medical diplomas from that authority, together with the other particulars required for the registration of such persons, the registrar may register every such person, upon payment of the registration fee, in the *Medical Register* without application from that person.

XVIII. A scheme for amending any previous scheme in operation under this Act for a medical board, or for revoking such scheme and making a new scheme, may from time to time be agreed or submitted and confirmed, and when confirmed shall come into operation, in like manner as near as may be as an original scheme under this Act.

A scheme under this Act, besides providing for the constitution, proceedings, powers, and duties of the medical board, may provide for the relations between the board and other boards and the General Medical Council, and for the fees to be paid on admission to the examinations of the board, and the application of such fees, and generally for such matters as appear to be necessary or proper for carrying into effect the scheme.

*Medical Authorities.*—XIX. Every medical authority shall give to the General Medical Council such information respecting a registered practitioner who has received a diploma from that authority, and respecting the grant or withdrawal of diplomas by that authority, as the General Medical Council from time to time require.

XX. A medical authority without prejudice to any other power vested in them may from time to time by a statute or by-law made with the approval of the Privy Council constitute a new medical diploma to be granted by them to persons who have obtained qualifying certificates from a medical board under this Act, and may attach to that diploma such rights and privileges in connection with the said authority as may be from time to time provided by any such statute or by-law.

The power of a medical authority under this Act or otherwise to grant a medical diploma shall extend to the granting of that diploma

to persons of both sexes, provided that—(1) this enactment shall not render compulsory the exercise of that power; and (2) a woman who receives a medical diploma from a medical authority who at the commencement of this Act have not any obligation to grant, and have not before the commencement of this Act granted a medical diploma to any woman, shall not, in respect of that diploma, except so far as the medical authority otherwise in their discretion provide, be entitled to any share in the government, management, or proceedings of that authority.

XXI. Nothing in any Act or in any charter, statute, or by-law, shall prevent a medical authority from carrying into effect a scheme for a medical board or other scheme under this Act, or otherwise from carrying into effect this Act, but such medical authority without prejudice to any other power of repealing or altering may, by a statute or by-law made, with the approval of the Privy Council, repeal, or alter a provision of any Act, charter, statute, or by-law which appears to be inconsistent with such scheme or with this Act, or which it appears to be necessary or proper to repeal or alter for the purpose of carrying into effect the scheme or this Act, and the statute or by-law when so approved, shall have effect as if it were enacted in this Act.

*Unregistered Persons.*—XXII. If a person who for gain either practises medicine or surgery, or a branch of medicine or surgery, or is engaged in the cure or treatment of diseases or injuries, and is not for the time being registered in the *Medical Register*, takes or uses the designation of any qualification or medical diploma which entitles a person to be so registered (including any recognised medical diploma granted in a British possession or foreign country), or the designation of licentiate in or professor of medicine and surgery, or medicine or surgery or a branch of medicine or surgery, or the designation of physician, surgeon, apothecary, or doctor, or any designation used to distinguish registered practitioners of medicine or surgery or of a branch of medicine or surgery, or any designation implying that he has obtained a qualifying certificate under this Act, or is registered or entitled to be registered in the *Medical Register*, or is duly qualified to practise medicine or surgery or a branch of medicine or surgery, he shall for every such offence be liable, on summary conviction, to a fine not exceeding twenty pounds.

Provided that a person shall not be liable to such fine if he shows that he is not ordinarily resident in the United Kingdom, and holds a medical diploma which entitles him to practise in a British possession, or foreign country.

If a person who for gain either practises medicine or surgery, or a branch of medicine or surgery, or is engaged in the cure or treatment of diseases or injuries, wilfully takes or uses any of the above-mentioned designations to which he is not entitled, he shall for every such offence be liable on summary conviction to a fine not exceeding twenty pounds.

If a person not for the time being registered in the *Medical Register* gives any certificate which, under the Medical Act 1858 is invalid unless signed by a person so registered, he shall be liable on summary conviction to a fine not exceeding twenty pounds.

A prosecution for an offence under this section shall not be instituted by a private person, except with the consent of the General Medical Council, or of some branch medical council, but may be instituted by the General Medical Council, by a branch medical council, or by a medical authority, if such Council or authority think fit.

This section shall not prevent a person, who lawfully holds a license in dentistry or in dental surgery of, or a certificate of fitness to practise as a dentist from, any of the medical authorities, from taking or using the designation of licentiate in dentistry or in dental surgery, or of certified dentist, and shall not prevent a person from using the designation of midwife, nor, if such person lawfully holds a license in midwifery of, or a certificate of fitness to practise as a midwife from, any of the medical authorities, from taking or using the designation of licentiate in midwifery or certified midwife, and shall not impose a fine on such person for taking or using such designation.

*Dentists.*—XXIII. 1. The General Medical Council may, if they think fit, submit to the Privy Council a scheme for the examination, licensing, and registration, under the control of the General Medical Council, of dentists, and such scheme when approved by the Privy Council shall have effect as part of this Act, subject to being from time to time revoked, altered, and added to, by a subsequent scheme submitted by the General Medical Council to, and approved by, the Privy Council.

2. The examinations may be conducted by any medical board or boards, authority or authorities, who consent thereto, or by persons appointed by the General Medical Council or otherwise, as provided by the scheme.

3. Every person who is certified to have shown by his examination that he is qualified to practise dentistry shall be licensed, either by the General Medical Council or by a medical authority, as may be provided by the scheme, to practise dentistry, and be entered in the dentists' register upon payment of such registration fee, not exceeding five pounds, as may be fixed by the scheme.

4. There shall also be entered in the dentists' register in one alphabetical list with the above-mentioned licentiates, every person for the time being registered in the *Medical Register* who applies to be entered in the dentists' register and pays the said registration fee, and also every person who at the date of the scheme coming into operation—(a) holds a license in dentistry or in dental surgery of, or a certificate of fitness to practise as, a dentist from any of the medical authorities; or (b) is *bonâ fide* engaged in the practice of dentistry either separately or in conjunction with the practice of other branches of medicine or surgery; and claims to be registered before the expiration of twelve months after the scheme comes into operation, or any longer period allowed by the scheme, and produces sufficient evidence of his title so to be registered, and pays the said registration fee.

5. There shall be also entered in the dentists' register, in separate alphabetical lists, such colonial or foreign dentists as are authorised by the scheme to be so registered, and the scheme shall make the like provision for the registration of colonial and foreign dentists as is made by this Act with respect to the registration of colonial and foreign practitioners in the *Medical Register*.

6. The scheme may provide for the like matters as can be provided for by a scheme for a medical board, and also for applying to dentists with such modifications and exceptions as are contained in the scheme, the provisions of the Medical Acts 1858 to 1878, with respect to examination rules, to medical boards, to registers (including the provisions respecting falsification, or false or fraudulent representation or declaration), and to erasure from and restoration to the *Register*, subject as follows—(a) The registration of a person in the dentist's register shall entitle that person to practise dentistry, but not any other branch of medicine or surgery, and shall not entitle him to assume any designation which a person not registered in the *Medical Register* is forbidden by this Act to assume, except that a person registered in the dentists' register may take and use the designation of dentist, or dental practitioner, or any designation implying that he is duly qualified to practise dentistry, so that such designation do not imply that he is duly qualified to practise any other branch of medicine or surgery; (b) The register of dentists shall be from time to time, and at least once a year, printed, published, and sold, either in one volume with the *Medical Register*, or separately, as the General Medical Council from time to time direct.

7. After a scheme under this section comes into operation, a person shall not be entitled to recover any charges for any advice, attendance, or operation in relation to dentistry, unless he is registered in the *Medical Register*, or in the dentists' register, under this section.

8. After a scheme under this section comes into operation, if a person who for gain practises dentistry, and is not registered in the *Medical Register* or in the dentists' register under this section, takes or uses the designation of dentist, either alone or in combination with other words, or of dental practitioner, or any designation implying that he is registered in the dentists' register, or that he is duly qualified to practise dentistry, such person shall be liable on summary conviction to a fine not exceeding twenty pounds.

Provided that a person shall not be liable to such fine if he shows that he is not ordinarily resident in the United Kingdom, and is entitled by law to practice dentistry in a British possession or some foreign country, and did not use a designation implying that he is registered in the dentists' register.

9. A prosecution for an offence under this section shall not be instituted by a private person, except with the consent of the General Medical Council, or of some branch medical council, but may be instituted by the General Medical Council, by a branch medical council, or by a medical authority, if the Council or authority think fit.

*Midwives.*—XXIV. 1. The General Medical Council may, if they think fit, submit to the Privy Council a scheme for the examination, licensing, and registration, under the control of the General Medical Council, of midwives; and such scheme, when approved by the Privy Council, shall have effect as part of the Act, subject to being from time to time revoked, altered, and added to by a subsequent scheme submitted by the General Medical Council to, and approved by, the Privy Council.

2. The examinations may be conducted by any medical board or boards, authority or authorities, who consent thereto, or by persons appointed by the General Medical Council, or otherwise as provided by the scheme.

3. Every person who is certified to have shown by her examination that she is qualified to practise midwifery shall be licensed, either by the General Medical Council or by a medical authority, or otherwise as may be provided by the scheme, to practise midwifery, and be entered in the midwives' register, upon payment of such registration fee, not exceeding five pounds, as may be fixed by the scheme.

4. There shall also be entered in the midwives' register in one alphabetical list with the above-mentioned licentiates every person not registered in the *Medical Register* who at the date of the scheme coming into operation—(a) holds a licence in midwifery of, or a certificate of fitness to practise as a midwife from, any of the medical authorities; or (b) is *bonâ fide* engaged in the practice of midwifery, and who claims to be registered before the expiration of twelve months after the scheme comes into operation, or any longer period allowed by the scheme, and produces sufficient evidence of her title to be so registered, and pays the registration fee.

5. The scheme may provide for local examinations and local registers; and any justices, commissioners, grand jury, council, board, or other local authority having any power of local government or of rating, may, if they think fit, undertake at their own expense any power given to them by a scheme under this section in relation to examinations and registers; and, if they do so, shall have the same power of instituting prosecutions for offences under this section as is given to a branch medical council.

6. The scheme may also provide for the like matters as can be provided for by a scheme for a medical board, and also for applying to midwives, with such modifications and exceptions as are contained in the scheme, the provisions of the Medical Acts 1858 to 1878 with respect to medical boards, to examination rules, to registers (including the provisions respecting falsification, or false or fraudulent representation or declaration), and to erasure from, and restoration to, the *Register*; subject as follows: (1.) The registration of a person in the midwives' register shall entitle that person to practise midwifery, but not any other branch of medicine or surgery, and shall not entitle that person to assume any designation which a person not registered in the *Medical Register* is forbidden by this Act to assume; except that a person registered in the midwives' register may take or use any designation implying that such person is duly qualified to practise midwifery. (2.) The register of midwives shall be from time to time, and at least once a year, printed, published, and sold, as directed by the scheme and subject thereto, either in one volume with the *Medical Register*, or separately, as the General Medical Council from time to time direct.

After a scheme under this section comes into operation, if any person who, for gain, practises midwifery, and is not registered in the *Medical Register* or in the midwives' register under this section, takes or uses the designation of registered midwife, or any designation implying that such person is registered in the midwives' register, or is duly qualified to practise midwifery, such person shall be liable, on summary conviction, to a fine not exceeding five pounds.

Provided that a person shall not be liable to such fine if she shows that she is not ordinarily resident in the United Kingdom, and is entitled by law to practise midwifery in some British possession or foreign country, and did not use a designation implying that she is registered in the midwives' register.

A prosecution for an offence under this section shall not be instituted by a private person, except with the consent of the General Medical Council or of some branch medical council, but may be instituted by the General Medical Council, by a branch medical council, or by a medical authority, if the Council or authority think fit.

*Miscellaneous.*—XXV. All powers vested in the Privy Council by the Medical Acts 1858 to 1878 may be exercised by any two or more of the Lords and others of Her Majesty's most honourable Privy Council.

Any order made by the Privy Council or any appeal to them under this Act, may be made conditionally or unconditionally, and may make such terms and directions as to the Privy Council seem just.

XXVI. The General Medical Council may delegate to any branch medical council, medical board or boards, medical authority or authorities, or to any person or persons consenting thereto, the duty of framing any examination rules, or of framing any scheme for the purposes of this Act, and such rules and scheme when so framed, if approved by the General Medical Council, may be submitted by them to the Privy Council in like manner as if they had been framed by the General Medical Council.

XXVII. Any offence under this Act which may be prosecuted on summary conviction, and any fine under this Act recoverable on summary conviction, may be prosecuted and recovered in like manner as an offence and penalty under the Medical Act, 1858.

XXVIII. All fines under this Act, save as herein expressly pro-

vided, and all penalties under the Medical Act, 1858, shall, notwithstanding anything in any Act relating to municipal corporations or to the metropolitan police courts, or in any other Act, public or local, be paid to the treasurer of the General Medical Council.

XXIX. Where by an Act relating to lunatics or lunatic asylums a certificate is required from a physician, surgeon, apothecary, or medical practitioner, such certificate may be given by any registered medical practitioner, in any part of the United Kingdom.

If such practitioner gives a certificate under any such Act which states or certifies anything falsely, or gives a certificate for admitting a lunatic into an asylum or house in which such practitioner or his father, son, brother, or other relative, or his partner is interested, or of which he is the medical attendant, he shall be guilty of a misdemeanour, and be liable to fine or imprisonment, or both.

A person, not being a registered medical practitioner, who signs a certificate under any such Act in which he is described as a physician, surgeon, apothecary, or medical practitioner, shall be guilty of a misdemeanour, and liable to fine or imprisonment, or both.

A medical practitioner who gives a certificate under any such Act without having seen and carefully examined the person named therein, or in any way gives the same contrary to the provisions of such Act, shall be liable on summary conviction to a fine not exceeding fifty pounds.

Where the certificate in respect of which the offence was committed purported to be granted under an Act relating to lunatics or lunatic asylums in England, an offence against this section, wherever committed, may be prosecuted by the secretary to the Commissioners of Lunacy, or by the clerk of any visitors of lunatics, or by some person authorised by the Attorney- or Solicitor-General for England, or such commissioners or visitors, and not otherwise.

Where the certificate in respect of which the offence was committed purported to be granted under an Act relating to lunatics or lunatic asylums in Scotland, an offence against this section, wherever committed, may be prosecuted, and a fine under this section may be recovered, on proceedings taken by the secretary to the General Board of Lunacy in Scotland, or by the procurator fiscal, or by some person authorised by the Lord Advocate, General Board of Lunacy, or procurator fiscal, and not otherwise.

All fines under this section shall be payable and applied in like manner as fines under the Act relating to the certificate in respect of which the offence was committed.

XXX. Nothing in the Medical Act, 1858, shall prevent a person holding a medical diploma entitling him to practise medicine or surgery in a British possession from holding an appointment in a vessel registered in that possession.

XXXI. An order confirming a scheme or examination rules under this Act, and the scheme and rules therein referred to, shall be deemed to have been duly made and authorised by this Act, and the validity thereof shall not be questioned in any legal proceedings whatever.

Every such order, together with the scheme and rules therein referred to, shall be laid before both Houses of Parliament as soon as conveniently may be after it is made, if Parliament be then in session, and if not, after the beginning of the then next session of Parliament.

XXXII. Subject to the other provisions of this Act, all notices and documents required by or for the purposes of this Act to be sent may be sent by post, and shall be deemed to have been received at the time when the letter containing the same would be delivered in the ordinary course of post; and in proving such sending it shall be sufficient to prove that the letter containing the notice or document was prepaid, and properly addressed, and put into the post.

Such notices and documents may be in writing or in print, or partly in writing and partly in print, and when sent to the General Medical Council, or a medical board, or a medical authority, shall be deemed to be properly addressed, if addressed to the General Medical Council, medical board, or medical authority, or to some officer of such council, board, or authority, at the principal office or place of business of such council board or authority; and when sent to a person registered in the *Medical Register*, shall be deemed to be properly addressed if addressed to him according to his address registered in that register.

XXXIII. In this Act, unless the context otherwise requires, the expression "General Medical Council" means the General Council of Medical Education and Registration of the United Kingdom; the expression "medical authorities" means, as regards each part of the United Kingdom, the authorities in that behalf mentioned in the in the second schedule to this Act; the expression "medical corporations" means as regards each part of the United Kingdom, such of the medical authorities of that part as are not universities; the expression "diploma" means any diploma, degree, fellowship, mem-

bership, licence, letters testimonial, certificate, or other title, status, or document granted by any university, corporation, college, or body; the expression "medical diploma" means a diploma in respect of medicine or surgery, or some branch of medicine or surgery, and includes a licence or authority to practise medicine or surgery granted by any department of or persons acting under the authority of the government of the country or place (whether within or without Her Majesty's dominions) in which the license or authority is granted; the expression "British Possession" means any part of Her Majesty's dominions, exclusive of the United Kingdom; the expression "medical registrar" means the registrar of the General Medical Council, and the expression "local registrar" means a registrar of a branch medical council, and this Act should apply, so far as circumstances admit, to the local registrar for England as if he were a different person from the medical registrar; the expression "medical register" means the register kept by the medical registrar in pursuance of the Medical Act, 1858, as amended by this Act.

XXXIV. The Acts mentioned in the third schedule to this Act are hereby repealed to the extent in the third column of that schedule mentioned, as from the commencement of this Act; provided that this repeal shall not affect anything done or suffered, or any right or title acquired or accrued, or any offence committed, before such repeal takes effect, or any remedy or proceeding in respect thereof, or any power of the General Medical Council to make any order in relation thereto; and any person entitled before such commencement to be registered in the *Medical Register* may be registered accordingly.

#### FIRST SCHEDULE.—*The Medical Acts.*

Year and Chapter of Act.	Title.	Short Title.
21 and 22 Vict., c. 90 ..	An Act to regulate the qualifications of practitioners in medicine and surgery	The Medical Act (1858)
22 Vict., c. 21 .. ..	An Act to amend the Medical Act (1858)	The Medical Act (1859)
25 and 26 Vict., c. 91 ..	An Act to incorporate the General Council of Medical Education and Registration of the United Kingdom, and for other purposes	The Medical Act (1862)
31 and 32 Vict. c. 29 ..	An Act to amend the law relating to medical practitioners in the colonies	The Medical Act Amendment Act (1866)
39 and 40 Vict., c. 40 ..	An Act for enabling legally qualified medical practitioners to hold certain public medical appointments, and for amending the Medical Acts	The Medical Practitioners Act (1876)

#### SECOND SCHEDULE.—*Medical Authorities.*

##### MEDICAL AUTHORITIES OF ENGLAND.

The University of Oxford.	The Royal Coll. Phys. of London.
The University of Cambridge	The Royal Coll. Surgs. of England.
The University of Durham.	The Apothecaries Society of London.
The University of London	

##### MEDICAL AUTHORITIES OF SCOTLAND.

The University of Edinburgh.	The Royal Coll. Phys. of Edin.
The University of Aberdeen	The Royal Coll. Surgs. of Edin.
The University of Glasgow	The Faculty of Physicians and Surgeons of Glasgow.
The University of Saint Andrew's	

##### MEDICAL AUTHORITIES OF IRELAND.

The University of Dublin	The Royal College of Surgeons in Ireland.
The Queen's University in Ireland.	
The King & Queen's Coll. Phys. Irl.	The Apothecaries Hall of Ireland.

#### THIRD SCHEDULE.—*Acts Repealed.*

*Note.*—A description or citation in this schedule of a portion of an Act is inclusive of the words, section, or other part first or last mentioned, or otherwise referred to as forming the beginning or as forming the end of the portion described in the description or citation.

Date and Chapter of Act.	Title.	Extent of Repeal.
3 Hen. VIII, c. 11 ..	An Act concerning physicians and surgeons	The whole Act
5 Hen. VIII, c. 6. . .	An Act that surgeons be discharged of constableness and other things	The whole Act
14 and 15 Hen. VIII, c. 5.	An Act concerning physicians	Section three and so much of the residue as restricts persons not admitted by the College of Physicians from practising medicine or surgery
32 Hen. VIII, c. 40 ..	Concerning physicians	The whole Act

[Table continued.]

Date and Chapter of Act.	Title.	Extent of Repeal.
32 Hen. VIII, c. 42 ..	Concerning barbers and chirurgions	Section one from "and that all persons of the said company" to the end of the section so far as regards surgeons; sections two & four, and so much of section five as relates to surgeons
34 & 35 Hen. VIII, c. 8 ..	An Acte that peroues being no cōen surgeons maie mynistr medicines outwards	The whole Act
18 Geo. II, c. 15 ..	An Act for making the surgeons of London two separate and distinct corporations	Sections nine and ten and so much of the residue of the Act as restricts persons not tried and examined as therein mentioned from practising surgery
55 Geo. III, c. 194 ..	An Act for better regulating the practice of apothecaries throughout England and Wales	So much as restricts persons who have not obtained such certificates as therein mentioned from practising medicine or surgery
21 and 22 Vict., c. 90 ..	The Medical Act	Section 14 from "and" to erase" to the end of the section, section 15, section 16 from "as nearly" to end of section, section 19, section 24 down to "education being one of them and", section 25, section 26, section 27 down to "called the Medical Register and", section 28, section 29, section 30, section 40, Schedule A, from "or doctor of medicine by doctorate granted" to end of schedule, and Schedule D.
22 Vict., c. 21 ..	An Act to amend the Medical Act (1858)	The whole Act except section four
36 and 37 Vict., c. 55 ..	The Medical Act (University of London), 1873	The whole Act

39 and 40 Vict., c. 41 ..	An Act to remove restrictions on the granting of qualifications for registration under the Medical Act, on the ground of sex.	The whole Act

## ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary meeting of the Fellows was held on Monday last, the 19th instant, to consider whether, under any circumstances, the College was prepared to grant its licence to practise physic to women.

The following resolution was moved by Sir G. Burrows, and seconded by Dr. West: "The Royal College of Physicians, having considered the important question of granting licences to practise physic to women, resolves—That the College do steadily adhere to the terms of its charter, and do not grant its licence to practise physic to women."

An amendment was moved by Dr. Maudsley, and seconded by Dr. J. Pollock—"That this College is prepared to grant its licence to women who submit to all the requirements of medical study and the tests of examination which it considers sufficient for men." The amendment, on being put, was lost. The original motion was carried by a large majority.

## CONJOINT COMMITTEE ON THE COUNTY GOVERNMENT BILL.

ON Wednesday (the 14th instant) a meeting of the Conjoint Committee of the British Medical and Social Science Association was held under the presidency of Mr. Powell. The attendance was large. A letter was read from Dr. Stewart, resigning the membership of the Committee on the ground of ill-health, and was received with expressions of sorrow and acknowledgments of his long and valuable services. Mr. Michael and Captain Clode having expressed a wish also to retire, a subcommittee was appointed to report as to the secretariat in the constitution of the Joint Committee. A long discussion took place on the County Government Bill, resulting in a resolution that the secretaries should draw up a memorial to the Government, and submit the same at the next meeting of the Joint Committee.

## THE MEDICAL ACTS AMENDMENT BILL.

WE understand that the General Medical Council will be summoned to meet on April 10th, in order to consider the Medical Acts Amendment Bill of the Government.

## HOSPITAL AND DISPENSARY MANAGEMENT.

## SUSSEX COUNTY HOSPITAL.

THE annual Court of the Governors of the Sussex County Hospital was held lately. The Earl of Chichester was appointed Treasurer. The balance-sheet adopted showed an excess of expenditure over receipts amounting to £943. Three resolutions, embodying a proposal for the establishment of a Convalescent Home in immediate connection with the Hospital, provoked a long discussion. The principle was approved; but, on an amendment, the matter was referred back to the Committee to report on details.

## THE INCOMES OF MEDICAL CHARITABLE INSTITUTIONS.

THE following comparative statement of the incomes of the metropolitan medical charitable institutions for the years 1875-6 and 1876-7 is taken from the new edition of the *Classified Directory to the Metropolitan Charities*. Where the income has decreased, it is indicated by italics.

	1875-6.	1876-7.
18 General Hospitals ..	£259,337 0 0 ..	£315,517 0 0
10 Consumption Hospitals ..	45,911 0 0 ..	46,136 0 0
5 Ophthalmic Hospitals ..	12,833 0 0 ..	13,134 0 0
3 Orthopaedic Hospitals ..	4,039 0 0 ..	3,467 0 0
4 Skin-Hospitals ..	3,050 0 0 ..	4,024 0 0
17 Hospitals for Women and Children ..	55,326 0 0 ..	54,304 0 0
5 Lying-in Hospitals ..	7,076 0 0 ..	7,327 0 0
23 Miscellaneous Special Hospitals ..	89,294 0 0 ..	100,001 0 0
	£486,918 0 0	£542,999 0 0
33 General Dispensaries ..	23,003 0 0 ..	25,842 0 0
13 Provident Dispensaries ..	9,256 0 0 ..	8,638 0 0
2 Institutions for Vaccination ..	2,750 0 0 ..	2,700 0 0
5 Ditto for Surgical Appliances ..	10,337 0 0 ..	0,157 0 0
33 Convalescent Institutions ..	39,712 0 0 ..	40,245 0 0
13 Nursing Institutions ..	3,642 0 0 ..	9,181 0 0
	£88,707 0 0	£96,783 0 0

## THE LEEDS HOSPITAL FOR WOMEN AND CHILDREN.

THE twenty-fifth annual report of this institution has lately been published, and shows that the hospital has been actively at work during 1877. During the year, 350 in-patients were treated, and 1,190 out-patients. This shows a decrease in the number of out-patients, as compared with 1876; and we gladly accept the statement, in the report, that this arises from the greater discrimination which has been exercised in the out-patient department in admitting persons to the benefits of the charity. The report adds: "With reference to the out-patient system at public hospitals, your medical officers are quite aware that it is liable to abuse and requires reforming; and a growing feeling exists in the metropolis, and in all our large cities and towns, that more care should be exercised with regard to the indiscriminate reception of out-patients; and that the expenditure of the funds of the medical charities should be more carefully administered; and that the working classes in good wages should be induced and encouraged to provide, by means of sick clubs, self-supporting dispensaries, and other agencies for medical aid, for themselves and families without charitable assistance."

## GLAMORGANSHIRE AND MONMOUTHSHIRE INFIRMARY.

THE annual meeting of this institution was recently held in the Town Hall, Cardiff. From the report, it appears that a larger number of patients had been relieved at the infirmary during 1877 than in any previous year. Indeed, in the out-patient department, the increase has been so considerable that it has been found necessary to appoint three additional medical officers with special charge of out-patients. Upon this subject, Dr. Sheen made some excellent remarks. Referring to the increased number of out-patients, he said there were various ways of looking at that fact. He regarded it as by no means a subject for congratulation; rather for regret; for he was firmly convinced, from his experience of six or seven years, that a large number of people were receiving the benefits of the institution who were not fit and proper objects of charity—people in a position to pay a small fee to a medical man, or a contribution to a club. The working men of Cardiff and its

neighbourhood subscribed to the infirmary, during the year, £678, through their "Saturday Committee". This serves to show how much they might do for themselves, if they were encouraged to form a system of provident dispensaries.

#### TWICKENHAM PROVIDENT DISPENSARY.

THIS dispensary has issued its first report; but, as the institution has only been in existence six months, we can scarcely expect that much progress has been made, especially when we remember the difficulties which all provident dispensaries in and around the metropolis have to contend with. We observe that the first three months were almost entirely occupied in making the dispensary known. In the next three months, two hundred and fifty members were enrolled. In such a place as Twickenham, there must be plenty of scope for such an institution. We trust the managers will persevere in their good work, being assured that the current of public and professional opinion is setting in their favour, and that they cannot assist their poorer neighbours in a better way than by helping them to provide against the time of sickness.

#### THE CHILDREN'S HOSPITAL, MANCHESTER.

ON January 30th, three new pavilions were opened in connection with the Children's Hospital, Manchester; and thus the buildings which have recently been erected at Pendlebury were completed. The structure consists of a front administrative block, a spacious corridor one hundred yards long, and six pavilions branching off from it. It is considered to equal, if not to surpass, any hospital in the kingdom which is devoted to the same purpose. It contains one hundred and sixty-eight beds, and the total cost has been about £40,000. It is situated three or four miles out of the city; but this disadvantage, if it be a disadvantage, is compensated by the dispensary which the board maintains in Gartside Street, and which is in constant communication with the hospital. Thus the dispensary is in the midst of the population, while the patients who are admitted through it into the hospital have all the benefits of the country. Another novel plan is, we understand, about to be adopted; the medical staff are to be paid for their services. This system, though general on the Continent, is not common in this country; but there is much to be said in favour of it.

#### HOSPITAL REFORM.

Sir,—A statement has just been published, on the authority of the Honorary Secretary, that, during the year 1877, the Governors of the London Hospital "have been compelled to sell out £21,770 Stock, besides borrowing nearly £5,000, in order to meet the current expenses".

It seems to me that a large number of people must be prevented from subscribing to hospitals by their pertinacious neglect of reform. I have myself been reluctantly holding back for some years on this account, anxiously waiting for the improved administration repeatedly advocated by leading members of the medical profession. A system of inquiry into the circumstances of each applicant ought surely to be adopted. Persons found to be in a position to contribute towards the cost of their treatment should be made to do so; and those who have received parish relief, unless requiring special treatment, should be referred to the workhouse infirmaries. I know, from my own experience, that the London Hospital, for instance, habitually admits what may be termed ordinary "pauper" cases requiring no special treatment, and that persons suffering from ordinary illnesses exchange the workhouse infirmaries for that hospital with impunity. The plan suggested would augment the funds, obviate the necessity of refusing admission to many legitimate cases for whom at present there is frequently no room, and also tend to encourage thrift.

I am, sir, your obedient servant, A. G. CROWDER.

\* \* Mr. Crowder's long experience in East-end work entitles him to speak with authority and unusual personal knowledge. We have long since arrived at similar conclusions, and indeed only recently pointed briefly the moral which Mr. Crowder has forcibly expressed. The present management of the out-patients' department of hospitals is, we fully believe, morally more injurious to the population than it is physically beneficial; and the interests of science, of charity, and public economy alike suffer from the neglect and indifference with which hospital governors have long treated this vital question. In the letters which we published during the last year from a member of the Charity Organisation Society, a mass of information will be found on this subject, and we trust that the efforts of the Committee of the British Medical Association, appointed at the last annual meeting, will assist in bringing about some general measure of reform.

## SPECIAL CORRESPONDENCE.

### PARIS.

[FROM OUR OWN CORRESPONDENT.]

*The Faculty of Medicine.—Clinical Teaching at the Hôtel-Dieu.—The Paris Municipal Council and Hospital Nurses.—The New Hôtel-Dieu.—The Saint-Louis Hospital.*

THE winter session of the Faculty of Medicine closed on the 15th instant, and the summer session began the next day. The following is a list of the professors who are to lecture during the course: Natural History, M. Baillon.—Physiology, M. Béclard.—Morbid Anatomy, M. Charcot.—Surgical Pathology, M. Guyon.—Medical Jurisprudence, M. Rigal (officiating for M. Tardieu).—Pharmacology, M. Regnaud.—Obstetrics, M. Charpentier (officiating for M. Pajot).—Experimental and Comparative Pathology, M. Vulpian.—Medicine, M. Peter.—Hygiene, M. Bouchardat.—Therapeutics and Materia Medica, M. Gubler.—Clinical Medicine, MM. Sée (Hôtel Dieu); Lasègue (La Pitié); Hardy (La Charité); Potain (Necker).—Clinical Surgery, MM. Gosse (La Charité); Richet (Hôtel Dieu); Broca (Necker); Verneuil (La Pitié).—Clinical Obstetrics, M. Depaul (Hôpital des Cliniques).

Although the Hôtel Dieu has been occupied for some months, yet, owing to insufficiency of material, from the small number of patients allotted to each clinical professor and the unfinished state of the building, the clinical lectures in Medicine and Surgery could not be proceeded with. Even now, it is not known when these lectures will begin, as the number of patients has not been increased, and the operating theatres or lecture-rooms are not quite finished. The new Hôtel Dieu is intended to contain four hundred and thirty-two beds, which in cases of emergency may be increased to five hundred; but owing to a decision of the Municipal Council, which is omnipotent, they are reduced to half the first-mentioned number to prevent, as has been alleged, the evil effects of overcrowding. According to this arrangement, there are six wards wholly unoccupied, and the clinical professors, who in the old hospital used to have about one hundred patients each of both sexes, are now reduced to half that number. This decision of the Municipal Council has caused great disaffection among the hospital staff.

I may bring to notice another instance of officious, unjustifiable, and uncalled-for interference on the part of the Paris Council. It has been proposed by some of its members to substitute lay *garde-malades* or sick nurses for the sisters of charity employed at the hospitals, who for ages have been the only attendants on the patients at these institutions and elsewhere. The pretext for this radical change is that the state of celibacy, which is imposed on the sisters, whether voluntarily or otherwise, renders them unsuited for the occupations of sick nursing! The idea is notoriously opposed to all past experience. On the other hand, say the Municipal Councillors, lay women, and particularly mothers, are, from the very nature of their social position, better qualified for such delicate duties. Such an assertion cannot stand the test of critical examination. As far as my own experience and that of greater authorities go, the patients in the hospitals will not benefit by the change, for the experiment was made during the late Commune, when the sisters were unceremoniously turned out of the hospitals and replaced by lay women, which proved a lamentable failure. Soon after the suppression of the Commune, the sisters were restored to the hospitals, where they have been working with their wonted zeal; but some fastidious members of the Council have found out that these good sisters do more in the way of praying than attending to the patients, and yet it is a well known fact that they are to be seen in the wards before daylight in the morning, and retire to rest, and this when they can, only late at night. I cannot say that no good women can be found among the laity, but from the class where sick nurses are generally taken, at least in this country, good ones are the exception, for they are generally given to intemperate and pilfering habits.

The raising of the old Hôtel Dieu, which occupied several months, is now quite completed, and the ground on which it stood is being levelled and planted with trees. When this is finished, it will form one of the largest squares in Paris, as it is an extension of the "Parvis-Notre-Dame", the name given to the already spacious area in front of the venerable Cathedral. The new Hôtel Dieu is situated to the north of the Parvis, and exactly opposite to the site of the old building. It is composed of six pavilions of three storeys high, two of which are devoted to the general stores, etc., while the other four are occupied by the patients. The principal entrance is on the Parvis-Notre-Dame, and this part of the building is allotted to the offices and residence of the director. The portion facing the north, and overlooking the Seine,

is devoted to study-rooms, amphitheatres, dissecting-rooms, chemical and pharmaceutical laboratories, rooms for chemical and physical experiments and pathological researches, and a library. There are altogether eighteen wards, each containing twenty-four beds, and are heated by warm air issuing from an immense *calorifère* or stove, which is so regulated that the heat is distributed and kept up at an equable temperature. The pavilions are separated by squares, four in number, having an ornamental fountain in the middle of each, and planted with trees, where patients who are able may enjoy the open air in fine weather. Independent of these squares, there is an open terrace extending uninterruptedly along the whole length of the second floor, where the patients may take airing, and there is a closed gallery along the first floor when the weather does not permit the patients to go out of doors. For convalescents and patients not well enough to go out into the gardens, a closed gallery on the ground-floor, and comfortably heated, is left at their disposal. The wards are well ventilated, and this is insured by grated apertures over every other bed, independent of the windows, and which are kept permanently open in all seasons. This, I must say, is a grand step in the sanitation arrangements of a French hospital. Lifts are also established for the accommodation of the patients and for the general purposes of the hospital. The service is so divided that there are forty-eight beds, that is, twenty-four of each sex, for each physician and surgeon. The staff is composed of six physicians, three surgeons, and one pharmacist; five *internes* for the medical wards and six for surgery, one *interne* for pharmacy, and a certain number of *externes* for the three services, proportional to the number of patients. The underground portion of the building contains the kitchen, cellars, warm baths for ordinary purposes, and cold and vapour baths in the form of douches or otherwise. The establishment is complete in every respect; but, owing to the unfinished state of the building, clinical lectures, pathological researches, etc., are still in abeyance, and even divine service has to be performed in a ward fitted up for the occasion, as the chapel is not yet completed. This hospital is certainly a great improvement on the old one, and the change has not been effected a day too soon.

Many and great are the changes that are taking place all over Paris, not only in improving the town itself, but the wants of the hospitals and asylums are not overlooked. A large sum of money has lately been voted by the Municipal Council for the enlargement and improvement of the pathological museum attached to the Saint-Louis Hospital, which is unique of its kind, containing as it does some of the finest specimens in the world of skin-diseases, either natural or imitations in plaster of Paris. The bathing establishment of the hospital is to be entirely reconstructed, as it has been found wholly insufficient for the requirements of the hospital, which, as you are aware, is chiefly devoted to diseases of the skin.

## ASSOCIATION INTELLIGENCE.

### SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT MEETINGS.

THE first meeting of the above District for the present year will be held at the New Kentish Hotel, Tunbridge Wells, on Friday, March 29th, at 3 P.M.: F. MANSER, Esq., of Tunbridge Wells, in the Chair.

Dinner at 5 o'clock. Charge, 6s., exclusive of wine.

Members intending to read papers, or offer communications, are requested to forward notice of the same, not later than Thursday, the 21st instant, to the Honorary Secretary, in order that they may be inserted in the circular convening the meeting.

The following have been promised.

1. Dr. Fairlie Clarke: Case of Diffused Melanotic Cancer.
2. Cases by the Chairman: *a.* Spindle-celled Sarcoma; *b.* Long-standing Hydrocele cured by Injections of Port-wine and Spirits of Wine.

THOMAS TROLLOPE, M.D., *Honorary Secretary*.

9, Maze Hill, St. Leonard's-on-Sea, March 12th, 1878.

### SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE next meeting of this Branch will be held at Carmarthen, on Thursday, April 4th.

Members desiring to read papers, etc., are requested to forward the titles to Dr. Sheen, Cardiff, before the 28th instant.

ANDREW DAVIES, M.D. } *Honorary Secretaries*.  
ALFRED SHEEN, M.D. }

March 11th, 1878.

### NOTICE OF EXTRAORDINARY GENERAL MEETING.

NOTICE is hereby given, that an Extraordinary General Meeting will be held at the Queen's Hotel, Birmingham, on Tuesday, the 2nd day of April next, at three o'clock in the afternoon:

1. To consider requisition received from members of the Metropolitan Counties Branch, of which the following is a copy.

*To the President and Committee of the Council of the British Medical Association.*

Gentlemen,—We hereby request you to make arrangements for submitting the following resolutions to an early special general meeting of the British Medical Association.

- "1. That this meeting is of opinion that the Reports of the Proceedings of the Committee of Council should be published in as complete and intelligible a form as is consistent with the conduct of business; and that in no case should important resolutions affecting the general interests of the Association be omitted."
- "2. That this meeting desires to express its opinion that in the selection of a house for the Association, it is desirable that the Council, Committee, and consulting rooms should be separate from the printing and publishing offices."

2. To consider the privileges of lady-members.

By order of the Committee of Council.

FRANCIS FOWKE, *General Secretary*.

London, March 13th, 1878.

### YORKSHIRE BRANCH.

THE spring meeting of this Branch will be held at the Infirmary, Rotherham, on Wednesday, March 27th, at 3 P.M.

Members wishing to read papers or bring forward cases are requested at once to communicate with the Secretary.

After the meeting, the members will dine together at the Ship Hotel at 5 P.M. Tickets (exclusive of wine) 6s. 6d. each.

W. PROCTER, M.D., *Honorary Secretary*.

York, February 26th, 1878.

### WEST SOMERSET BRANCH.

THE spring meeting of this Branch will be held at the Railway Hotel, Taunton, on Thursday, April 11th, at 5 P.M.

The following question has been settled by the Council as the one on which members should be invited to express their opinion at the said meeting after dinner:—"Is the Use of Water desirable in Dressing Wounds?"

The Secretary requests that early notice be sent to him of the title of any communication intended to be brought forward at the meeting.

W. M. KELLY, M.D., *Honorary Secretary*.

Taunton, March 16th, 1878.

### NORTH OF ENGLAND BRANCH.

THE spring meeting of this Branch will be held at Hexham, on Thursday, April 25th.

Gentlemen who are desirous of reading papers, introducing patients, exhibiting pathological specimens, or making other communications, are requested to signify their intention to the Secretary at their earliest convenience.

G. H. PHILIPSON, M.D., *Honorary Secretary*.

Newcastle-upon-Tyne, March 12th, 1878.

### METROPOLITAN COUNTIES BRANCH.

A GENERAL meeting of this Branch will be held at 11, Chandos Street, Cavendish Square, on Wednesday, March 27th, at 8 P.M., when the adjourned discussion of Mr. Holmes's paper on Provident Dispensaries will be resumed, and the following resolutions will be submitted to the meeting:

1. That, in the opinion of this meeting, no patients ought to be admitted gratuitously at the out-patient departments of hospitals, except for medical reasons, shown by the recommendation of the patient by some medical authority.
2. That the poor, who are above the necessity of gratuitous out-patient relief under the Poor-law, would obtain more efficient medical attendance by paying the proper subscription to a provident dispensary than they now have at the free out-patient departments of hospitals.
3. That, if freed from the competition of the free hospitals and dispensaries, provident dispensaries might be founded in London, on principles fair both to the patients and to their medical attendants.
4. That the out-patient departments of public hospitals might be

connected with the institutions charged with the medical care of the poor, with great advantage to the public health and to medical education.

ALEXANDER HENRY, M.D. } *Honorary Secretaries.*  
W. CHAPMAN GRIGG, M.D. }

London, March 20th, 1878.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH : ORDINARY MEETING.

THE fifth ordinary meeting of the session 1877-8 was held in the Queen's College, Birmingham, on February 14th; present, Mr. SAMPSON GAMGEE, President, in the chair, and thirty-five members.

*New Members.*—The following gentlemen were elected members of the Branch: Messrs. W. G. Archer, H. R. Bracey, W. Leah, G. J. Lloyd, H. G. Lowe, M. Perceval, W. P. Whitcombe, W. M. Yeates, and Drs. Bostock, Hill, and H. Malet of Birmingham; Dr. Cunningham, Oldbury; Mr. R. Davies, Walsall; Dr. H. T. Shapley, Leamington; and Mr. V. G. Webb, Colshill.

*Communications.*—1. Mr. LAWSON TAIT exhibited a new form of Trocar for Abdominal Tapping, formed of a solid tube with a steel point, bevelled so as to follow a lancet-puncture. The point is sufficiently sharp to puncture a secondary cyst if necessary, but not sharp enough to do any harm except by reckless manipulation. The solidity of the instrument entirely prevents the possibility of the entrance of air, and enables the trocar to be used for exploration.

2. Mr. TAIT showed an Anomalous Growth passed by Rectum. The patient was sent to Mr. Tait as a case of ovarian tumour, but the growth was recognised to be intimately associated with the parietes, and to have intestine adherent in front of it. It suppurated, and discharged a large quantity of pus through the umbilicus. The growth in question then was passed by rectum, and the tumour has since almost entirely disappeared, only a small lump being left adherent to the umbilicus. Mr. Tait was quite unable to recognise the nature and origin of the growth. All he could say was, that it contained a large amount of unstriated muscular fibre.

3. Mr. TAIT also showed a small Scirrhus Cancer which he had removed from the Linea Alba.

4. Mr. TAIT exhibited a series of Casts of Children, all belonging to the same family, from Turkey, in which the sex had been mistaken owing to arrest of closure of the perinaeum. They were hypospadiac males, but had been named and brought up as females, until the elder, at about ten years of age, began to indicate the true nature of his genital apparatus.

5. Mr. TAIT also exhibited a case of Exophthalmic Goitre in process of cure.

6. Dr. BINDLEY showed a woman who was the subject of Lichen Planus.

7. Mr. SAMPSON GAMGEE exhibited a girl aged 11, whose right thigh he had amputated. The vessels were tied with catgut, the wound closed with silver sutures and styptic colloid, a drainage-tube having been previously introduced; the face of the stump was covered with an oakum pad, and perfect immobility secured with pasteboard splints and uniform compression. The first dressing was on the ninth day, the second on the fifteenth. Union was complete and solid in eighteen days with three dry dressings.

8. Mr. LAWSON TAIT read a paper, entitled Fifty Cases of Ovariectomy.—A discussion followed, in which the President, Mr. Oliver Pemberton, Mr. Baker, Dr. Savage, Dr. Hickinbotham, and Mr. Yates took part.

9. Mr. LLOYD OWEN read a paper on Nystagmus.—A discussion thereupon arose, in which Mr. Priestley Smith, Mr. Lawson Tait, and Dr. Russell shared.

### NORTH WALES BRANCH : INTERMEDIATE MEETING.

THE intermediate meeting of this Branch was held at the Owen Glyndwr Hotel, Corwen, on Friday, March 8th, at one o'clock; ROBERT ROBERTS, Esq., President, in the chair.

Letters of apology, etc., were read from Mr. Charles Williams of Northwich, Dr. Williams of Wrexham, and Dr. Roberts of Chester.

*New Members.*—The following new members were elected: Mr. David R. Jones (Corwen), Mr. Humphrey Roberts (Llanfaintallhaeri), Mr. David Griffiths (Gronant), Mr. Robert Roberts (Oakley Hospital, Festiniog), Mr. Thomas Ellis Roberts, M.B. (Oakley Hospital, Festiniog), and Dr. John E. Jones (Dolgelley).

*The Dental Practitioners Bill.*—A petition against the Dental Practitioners Bill was signed by all the members present.

*Admission of Ladies to the British Medical Association.*—A resolution was proposed and carried: "That, in the opinion of the members present, the admission of lady doctors to the proceedings of the British Medical Association is undesirable and to be deprecated."

*Communications.*—1. Dr. EYTON JONES exhibited a specimen of Aneurism of the Ascending Aorta, taken from a discharged soldier, whom he had treated for three months with large doses of iodide of potassium, chloral, low diet, and enforced rest.

2. Mr. R. W. J. EVANS exhibited a specimen of Molluscum Fibrosum, one of seven grape-like tumours that had been removed from the side of a woman in the Wrexham Infirmary.

3. Mr. JAMES WALKER gave his experience of the value of Hydrobromine Acid in conjunction with Quinine.

4. Dr. EYTON JONES related a case of Pneumonia in a boy aged 9, whose temperature for two days was 106½ deg., and the value of stimulants in his recovery.—A discussion took place, some members speaking highly of the value of stimulants, others equally as strongly insisting on the value of the tartar emetic treatment.

5. The PRESIDENT related a case of Tetanus, in which Chloral-Hydrate was so successful that the patient called it "physic gynecideirol".

*The Secretary.*—The HONORARY SECRETARY gave notice that, at the next annual meeting, he should resign his appointment, pressure of professional work compelling him to do so.

*Dinner.*—The members present, together with the Rector of Corwen and the Rector of Llangwm, adjourned to a most excellent dinner, at which the usual loyal and other toasts were ably proposed, responded to, and duly honoured.

### BATH AND BRISTOL BRANCH : ORDINARY MEETING.

THE fourth ordinary meeting of the session was held at the Museum and Library, Bristol, on Wednesday evening, March 13th. There were present Dr. MARSHALL, President, in the chair, and sixty-seven members.

*New Members.*—Mr. J. H. Pavey and Dr. Tunstall were unanimously elected members of the Association and this Branch.

*Communications.*—1. Dr. SWAYNE read a case of Puerperal Convulsions, which gave rise to a long discussion, during which Drs. Davey, Lawrence, and Harrison, and Messrs. H. Grace, Thompson, H. Swayne, Mason, and Dowson made remarks.

2. Dr. SPENCER read a paper on the Use of Salicylic Acid in combination with Opium and Aconite. An animated discussion followed this paper, in which Drs. Cole, Steven, E. L. Fox, Shaw, and Skerritt, and Mr. W. M. Clarke joined.—Dr. SPENCER then replied; and the meeting terminated.

## CORRESPONDENCE.

### THE APOTHECARIES' COMPANY v. SHEPPERLEY.

SIR,—The appeal made by Mr. Stanger, in your issue of the 9th instant, has met with a very satisfactory response; and I beg, on behalf of the Nottingham Branch of the Medical Defence Association, to acknowledge the receipt of many encouraging promises of support from influential medical men. It is not thought necessary or desirable to publish the names of those who have promised pecuniary assistance, especially as no consent has hitherto been obtained to such a course.

The importance of this prosecution to the profession at large can scarcely be overestimated, the issue involved being neither more nor less than the right of chemists and druggists to prescribe. It is obvious that, if we admit the "right" of prescribing at all, it is difficult to draw any line or limit where the practice shall cease, and chemists and druggists will become, to all intents and purposes, medical practitioners. The prefix "counter" to the word "prescribing" does not alter in the slightest degree the meaning of the latter word. If chemists can prescribe legally, there is no law which limits them to prescribe across a counter. If they visit a patient at his own residence, the offence is not in the visiting, but in the prescribing. Chemists and druggists have not received the professional training which would enable them to distinguish between the premonitory symptoms of dangerous diseases and what they are pleased to term "simple ailments"; the patient for whom they prescribe for across the counter on account of a cough or cold may be in reality suffering from consumption or heart-disease.

The case of the Apothecaries' Company v. Shepperley is a test case, and, from its very simplicity, will solve in the most decisive manner

the important question, Have druggists a *right* to prescribe? The chemists and druggists contend that they have a right to the practice of "counter-prescribing", and are fighting for this alleged right with all the weight, influence, and pecuniary support of a large and powerful association. The Nottingham Branch of the Medical Defence Association is but a small local society. Nevertheless, we hope to have the question finally settled, and, if the prosecution be successful, which we have good grounds for believing it will be, the Branch will be able and willing to meet all liabilities. But there is a proverbial uncertainty about law, and the Nottingham Branch feels that it is absolutely necessary to have a guarantee fund to provide against the possibility of an adverse decision or of an appeal to a higher court. It is with this object we are soliciting the aid of our medical brethren, and we look with confidence to the profession at large for such support as will enable us to fight the Chemists and Druggists' Association (the real, although not the nominal, defendant) on equal terms.—I am, yours obediently,

HENRY R. HATHERLY, Honorary Secretary, Nottingham Branch of the Medical Defence Association.

### THE DENTAL PRACTITIONERS' BILL.

SIR,—I was much disconcerted to read in your article of last week that you consider "this Bill may now be counted among the things of the past", although you think this to be regretted now that the objectionable clauses in it have been modified in much that was seriously open to objection, and admit a measure of the kind is much wanted, and that something will hereafter be provided for the dental profession without independent legislation on their part. As one of the early promoters of the measure, but from which I was compelled to withdraw with others when its objectionable characters, which I first pointed out would most certainly prevent its attaining success, were so unfortunately retained, I must express a strong hope that an object so essential to the public benefit may not, even for a time, be lost sight of now that its objectionable aspect no longer exists.

That any portion of the human frame endued with, to define it sharply, say, nerves and blood-vessels, and, moreover, representing organs which play no unimportant part in the animal economy, should be left to be dealt with by any individual who may possess the temerity or effrontery to call himself "a tooth doctor", irrespective of training or experience demanded in the case of all other similar structures, has evidently been, in such an age as this, a great oversight, and it seems lamentable an evil so apparent should be, even for a day longer than is possible, permitted to exist. *Deferred legislation* is tantamount to *interred legislation*; and, having aroused the sympathy and attention of the legislature to this great public need, I sincerely trust, through your able advocacy, the medical profession at least may be induced to afford their general support to a measure which, if not even now perfect in its very altered form, is, in its general principles, such that they, as guardians of the public welfare, may well uphold.—I am, etc.,

ALFRED COLEMAN, President of the Odontological Society.  
19, Savile Row, March 16th, 1878.

SIR,—As there appears to me to be considerable misapprehension as to the object and scope of the Dental Practitioners' Bill, now before Parliament, I hope that you will allow me to assign some of the reasons why, in my opinion, the Bill deserves the cordial support of the medical profession.

The chief object of the measure is to consolidate the scheme which was commenced some twenty years ago, when the dental profession placed itself under the guidance of the College of Surgeons; and, in consequence, the licence in dental surgery was granted by that College. Since that time, the licence has been very generally made use of by those entering the dental profession.

Exception was taken to the Bill in its original form, that it might allow dental licentiates to trespass on the ground occupied by surgeons. I do not myself think that these fears were well grounded; but, in deference to the opinions expressed by many members of our profession, the objectionable clauses have been removed, and there is nothing which can now interfere with any privilege of the profession.

On the other hand, little attention has been paid to one important privilege which this bill confers on the medical profession, and in virtue of which it will be able to exercise a complete control over the dental profession; and this is a desirable object, both as regards public and professional interest.

It is, I think, very inexpedient to do anything to facilitate the formation of specialities; but it must be remembered that dentists at present constitute a speciality, as it were, half outside the domain of medicine, and that it has acquired its position in the course of time with the con-

sent of the medical profession, and with the approval of the public. In nearly all other specialities, it is necessary that the practitioner should be a qualified medical man, and something more. In dentistry, however, there is so much that is purely technical, that it would prolong the education to an undue extent if all were expected to become members of the College, and then be educated as dentists; and, although it may be expedient that those wishing to take high rank in their class should become members or fellows of the College, it is not necessary that all should become qualified surgeons in order to practise as dentists. The College of Surgeons, therefore, acted wisely when they granted their licence with a curriculum in which part of the purely medical studies was omitted, and special technical subjects substituted, the total length of the curriculum being equivalent to that observed by candidates for the membership.

The alternative scheme is to allow the dentists to form their own corporation, independent of and uncontrolled by the Medical Council: a course of action which would, I think, be much more likely to interfere with the privileges of the profession. It is much to be regretted that this was allowed to be done by the pharmaceutical chemists. At present, they constitute a separate body, over which we exercise no control; and it would have been much more to the interest of the public if the chemists had been placed under the General Medical Council. Formerly, the College of Physicians had the power of visiting apothecaries' shops and of inspecting drugs. It is unfortunate that some controlling power was not preserved to our profession, for this would enable us to check irregular practice.

On these grounds, it is expedient that the dental profession should be placed under the Medical Council; and in order to do this, it is necessary to give the proposal a generous support, and to treat the question in a liberal manner and upon broad principles.

Yours obediently,

London, March 18th, 1878.

SEPTIMUS W. SIBLEY.

### LYING-IN HOSPITALS.

SIR,—We have read with much satisfaction, in the editorial notes of your JOURNAL of the 9th instant, the statement "that considerable changes are likely to be made in the management of the General Lying-in Hospital, York Road, with a view of increasing the efficiency of that old-established and endowed charity"; and what immediately follows, which more especially concerns the hospital to which we are physicians: "that the changes effected in the management of Queen Charlotte's Lying-in Hospital have, we hear, operated most satisfactorily in the reduction of the rate of mortality and in the production of excellent vital results, such as have not always been attained at that institution."

Our London lying-in hospitals have engaged, and are engaging, considerable attention in the profession, and rightly so; for we unhesitatingly state that the internal management of all our London lying-in hospitals has been up to quite recently deserving of the severest criticism, which a mortality of not less than one in thirty in the best of them clearly shows.

That condition commonly known as *hospitalism* was first brought to light in these institutions, and they were recently stated by the Registrar-General to be the pioneers in hospital sanitation; but, owing to a combination of false principles which regulated the internal management of these institutions, they have not only made no advance in sanitary matters during the last quarter of a century, but, on the contrary, they have fostered a state of things which has resulted in a mortality as stated above. The chief of these false principles were:

1. Leaving the entire medical superintendence of these institutions in the absence of the physicians in charge, in the hands of a matron, a scientifically trained resident medical superintendent not being deemed necessary;
2. Uniting the two duties of head nurse and midwife in one and the same person.

These defective principles have, in the case of one hospital, resulted in a death-rate as high as one in fourteen. Mr. Charles Hawkins, after twenty years' experience at Queen Charlotte's Lying-in Hospital, publicly stated, in July 1876, that he considered that lying-in hospitals should be closed, and that he lamented the day that he had been instrumental in the rebuilding of such a hospital; but he added that it was a problem which he left to accoucheurs to solve.

We—aided by the powerful influence of Dr. Gream, Senior Consulting Physician-Accoucheur, and assisted by his great experience in all matters of detail connected with the puerperal state, and recognising as he did the vital necessity and importance of placing a lying-in hospital in harmony with our present knowledge of hospital sanitation—were enabled to respond to Mr. Charles Hawkins's challenge.

The hospital was closed in November 1876 through an outbreak of puerperal fever, which caused the loss of eight lives out of eighty-eight women admitted within two months of the reopening of the hospital after its usual annual autumnal six weeks' cleaning, and whilst it was being worked in direct opposition to the wishes of Dr Gream and ourselves, and under the very same system, the effects of which had forced Mr. Hawkins to come to the afore-stated conclusion. We had, too, been compelled to work the hospital under the old system through an unfortunate medical vote in the Committee of Management.

The hospital was reopened on February 15th, 1877, under an entirely new system of management. The results of the working of the year under the old system, and of twelve months under the new, up to February 15th, 1878, we beg to append.

Statistical Table.

Women Delivered	1876.	1877.
Married .. .. .	164 .. ..	179 .. ..
Single .. .. .	252 .. ..	359† .. ..
Total .. .. .	416 .. ..	538‡ .. ..
Died .. .. .	19 .. ..	6 .. ..

Total deaths, including children .. ..	62 .. ..	15 .. ..
Proportion .. .. .	about 1 in 13 .. ..	about 1 in 70 .. ..

This diminished death-rate unfortunately excludes another most important factor, which it is very difficult to place statistically before you: it is shown by considerably diminished percentage in the "bad gettings up" and almost the entire absence of mischief in the pelvis, *i.e.*, pelvic peritonitis, cellulitis, and cystitis. There is another important fact, the exact interpretation of which we would rather leave to Professor Lister for an explanation, *i.e.*, the great absence of offensive lochia, the presence of which was the rule formerly, but is now the exception. These remarkable results have been obtained in a building possessing many structural defects and still requiring some important additions, which the general body of governors, upon our recommendation, have decided to remedy. The fundamental principles, however, upon which the hospital is constructed are, in our opinion, good.

The following is the basis upon which the internal management of the hospital has been changed.

1. The thorough reorganisation of the system of internal management.

2. The delivery of the patients by midwives summoned from without the hospital, and in labour-wards strictly set apart for that purpose.

3. Placing the entire medical control of the patients, in the absence of the physician in charge, in the hands of a qualified paid resident medical officer.

It would be tedious to your readers, and we should be trespassing too far upon your valuable space, were we to enter into minute details under these respective heads; but we may mention that, with regard to the first, and experience has proved it to be so, there is no matter of detail, however small, in regard to the safety of a patient in a lying-in hospital, to which attention should not be paid. The chief principles of the system under which we are at present working are as follows.

1. Making the matron head-nurse, and not allowing her to attend midwifery or even to enter the labour-wards.

2. The reduction of the number of patients in each ward from three to two persons; all our wards, with the exception of two, being small and containing only 2400 cubic feet of air in each.

3. Placing a nurse in each ward along with each set of patients allotted to her (usually two) during the time they remain in the hospital, and prohibiting her from entering any other ward but that in which she has charge of patients.

4. The habitual use of some disinfectant during the necessary ablutions of the patients, and for the washing of hands, vaginal tubes (all of which are made of glass, each ward having its own syringe), as well as for disinfecting the various utensils, etc. Every nurse, before taking charge of a fresh set of cases, has to undergo a system of thorough

purification (being required to be in the open air and take a disinfectant bath, and to have their clothes stove).

5. The stoving at a temperature of 250 deg. of every article of bedding, clothing, and linen used in the lying-in room, with each relay of patients.

6. The complete isolation of all the wards from the current of air in the main corridors by means of double doors to each ward; the frequent opening of windows, and the employment of a system of ventilation introduced by Mr. Peter Squire of Oxford Street.

7. The prohibition of the washing of floors during the stay of patients in the wards; the thorough fumigation and purification of the respective wards after they have been vacated; and allowing them to remain empty for a week, if possible, before they are again occupied.

—We remain, sir, your obedient servants,

WILLIAM HOPE, M.D., } Physicians to the In-patients of Queen

W. C. GRIGG, M.D., } Charlotte's Lying-in Hospital.

London, March 14th, 1878.

## THE COLLEGE OF PHYSICIANS AND MEDICAL WOMEN.

SIR,—There is said to be a mode of refusing a request so gracious that it removes all the sting of the refusal. Certainly there is a mode so ungracious that it aggravates a thousandfold the pain, namely, the refusing it before it is asked. This mode has been adopted by the London College of Physicians, when they called a meeting on Monday for the purpose of determining on a public announcement that they would not admit to examination any women, even for the lowest licence which they are empowered to grant. I am heartily ashamed of my College, and, at the risk of violating *secreta Collegii*, must shield myself from the possible imputation of having joined in that vote. There are two railways running from the same village to the same terminus. There are certain unpopular persons (say Russians or Turks) who travel first class by one of these lines. The other line puts up at its station a notice that no person in a caftan or a fez shall have even a third-class ticket. Is that folly, or is it a bullying insult? Yet I cannot see that it differs essentially from the position assumed by the College of Physicians in regard to the University of London. I call the degree of the University of London a first-class ticket, because no persons would apply for the licence who could write themselves M.D. London. Certainly no women would; for they, unwisely perhaps, have a great love of well-known and distinctive titles; they become Knights of the Star of India; they have been decorated with dukedoms, earldoms, baronies (I am not sure about baronetcies), and they will traverse, and have traversed, sea and land to be able to append M.D. to their names.

It would seem to be this M.D. which has acted as a red rag to our usually sedate fellows, and made them positively rude to their fellow subjects. They are so fearful of the public confounding all M.D.s together, that they hasten to make an opportunity of abjuring the connection. Is not the alarm needless, so long as they maintain their real superiority? Many years ago, we are told, the he-goats complained to their Maker that the she-goats wore beards; but they were consoled by Him with the assurance that the show was of little moment so long as the substance of virility remained to the *beati possidentes*.

"Sinite illis," inquit; "vanâ gloriâ fruit.  
Pares cum non sint vestre fortitudinis."

"Be satisfied," he would have said, "with the assurance of an athletic fellow that you have an average height of 5 foot 9, and are 36 inches round the waist, and with the opinion of your obstetricians that you are less liable than women to pregnancy and other sicknesses; and do not grudge them an ornamental distinction, which is really so common that you do not value it much."

If the University of London had rejected the petition of women to be admitted to their degrees, nobody could have blamed them, for they were forced to answer it one way or another. But the case was quite different with the College of Physicians; for they were assured on the highest authority that it did not matter the least to the success of the Conjoint Scheme, or of anything else, which way they determined, or whether they came to any determination at all. They were exactly in the position of a braggadochio who suspects a lady of having a secret liking for him, and then tells her publicly that he will not return the affection, even if she ask him. Surely the Royal College cannot do better than retract without delay their unhappy breach of good manners.—I am, Sir, yours faithfully,

London, March 21st, 1878.

T. K. CHAMBERS.

\* The average mortality since 1857 has been about 1 in 30.

† The largest number of single women admitted in a year.

‡ The largest number, with one exception, admitted in one year.

## MEDICO-PARLIAMENTARY.

HOUSE OF LORDS—Tuesday, March 19th, 1878.

### MEDICAL ACTS AMENDMENT BILL.

THE DUKE OF RICHMOND AND GORDON called attention to the subject of the Medical Acts and presented a Bill. He said: My lords, I wish to call your lordships' attention to some of the Medical Acts which are now in force, and to point out to your lordships in what manner I think they may require some amendment; and I shall conclude by presenting your lordships with a Bill, to be read a first time, which will, I hope, have the effect of remedying some of the defects which now exist, and of improving the law on the subject. My lords, I believe I am right in stating that every person is entitled by the common law to practise medicine in this country if that person be competent to do so; and there have been many Acts passed, during the last three hundred years, regulating the competency of the person and the manner in which that competency can be ascertained. So far back as the reign of Henry VIII, there is an enactment which enacts "that no person within the city of London or within seven miles thereof shall be entitled to take upon him to exercise the occupation of a surgeon except he be first examined and approved by the Bishop of London and the Dean of Paul's and four other professional advisers". And in the country no person was allowed, by the same Act of Parliament, to practise unless he had been first examined and approved by the bishop of the diocese and the vicar-general. My lords, both these clauses in this statute are still on the statute-book; and, unless I find some opposition on the part of the right reverend bench to my depriving them of the privileges which they formerly enjoyed—but which I hope, for the sake of mankind, they no longer practise [*laughter*—I shall ask your lordships to repeal them. At that time, it was assumed that every one possessed the double qualification of medicine and surgery, because one of the clauses of the Act sets out "that, forasmuch as the science of physic does comprehend, include, and retain as a special member and part of the same a knowledge of surgery, therefore be it enacted that any of the said company or fellowship of physicians, being persons chosen and admitted by the said president and fellowship of physicians, may from time to time, in the city of London or elsewhere within this realm, practise the said science of physic in all its members and parts, any acts or statutes to the contrary notwithstanding". It was assumed at that time that the science of physic included the practice of surgery. At the time of the passing of the Medical Act—to come down to a more recent period—of 1858, medical legislation was in a most unsatisfactory condition. There were various bodies in the three kingdoms who were all entitled to confer degrees. They were often in competition with one another, not, I am sorry to say, with a view of raising, but rather of lowering, the standard of education. Some of these bodies could grant degrees over the whole of the kingdom, whilst others were confined to that part of it to which the body belonged; so that it was possible, and might well happen, that the most competent physician—the most eminent physician—in England might be precluded from practising in Scotland or Ireland, and, *vice versa*, the same thing might happen—that is to say, the most eminent physicians in Scotland might not be able to practise in England. It is not, therefore, surprising that, for some years previous to 1858, various attempts were made to remedy this condition of things. But, owing to the jealousy of various persons who were to be affected, and the fear of losing certain privileges which they then possessed, no Bill at all was passed for some years. In 1858, however, Mr. Cowper introduced a Bill into the other House of Parliament, and that measure was approved and adopted by the Government of the late Lord Derby. The Bill which Mr. Cowper introduced into the House of Commons had three objects. The first was to raise to an uniform and sufficient standard the educational acquirements of all persons entering the medical profession; secondly, it provided that there should be an authoritative register, in which the names of all persons so qualified should be clearly set out and defined; and thirdly, it provided for removing the local jurisdiction, which restricted a competent man from practising in any part of the country except that in which the licensing body had authority. Those were the three objects which Mr. Cowper desired to obtain by his Bill, and, as I have said, that Bill was approved of and taken up by the Government. The preamble of that measure states "that it is expedient that persons requiring medical aid should be en-

abled to distinguish qualified from unqualified practitioners"; then it goes on to say, "be it therefore enacted", etc. Now, that is a principle we must all agree with—viz., that we should be able to distinguish between qualified and unqualified practitioners. The provisions of the Bill were drawn with that view, and I am bound to say that, to a certain extent—indeed to a great extent—that measure has been successful; but, through the lapse of time that has occurred since 1858, various things have occurred to show that it is desirable to amend that measure in some particulars. The mode which was provided by that measure for carrying out that which was then held necessary to distinguish between qualified and unqualified practitioners was first of all the setting up of a Medical Council. Then there was a very important clause in that measure—the nineteenth section—which suggested a course by which an uniformity in the qualification of candidates for the medical profession could be attained. The English bodies have been for some time engaged in trying to form a scheme under that section—a scheme well known to those who take an interest in this matter as the "conjoint scheme". That had for its object to include bodies representing medicine and surgery within a conjoint board. The difficulty experienced in connection with that has been great; and though up to the present time that difficulty has not been surmounted, yet I hope and believe that the English bodies will, before long, have come to such an agreement as will enable them to form a conjoint board. If that be done before the passing of this Bill, orders in Council will be issued to confirm it, and it will be left to other bodies in Scotland and Ireland to come in afterwards, if they think fit to do so. There is a difficulty in regard to Scotland, in consequence of the universities and various corporations existing there being somewhat different from the universities in this country. In consequence of this, it has not been found to be feasible up to the present time to include the Scotch bodies within a conjoint scheme, such as I have alluded to with regard to England. I trust that this difficulty is not one which is insurmountable. A provision will be inserted in the Bill by which the Scotch bodies, if they can come to an agreement, after the passing of the Act, for the formation of a conjoint board, will be able to form part of the board which will be set up in England. There has been an attempt made to provide for the establishment of a general board, but it has failed, and therefore each country has been kept distinct. But, at the same time, the Bill is entirely of a permissive character. Then there is a provision in the Bill for the confirmation by an order in Council of the establishment of a conjoint board. The Act of 1858 contains a provision for enabling persons practising in the colonies and elsewhere to be registered; but, as that provision only dealt with persons before the passing of the Act, there was nothing to fix the position of persons afterwards. That is a defect in the Act, and it has been discovered also that the clause providing penalties in the case of a person pretending to be registered when in reality he was not on the Register required amendment. I may also mention, as I shall show when I allude briefly to the provisions of the Bill, that the Act known as Russell Gurney's Act for enabling women to be examined by the College of Surgeons was so drawn, that it compelled them to be members of the senate of the corporation, which was not intended when the Act was passed. These are the conditions of the law as it at present stands, and I think I shall best suit your lordships' convenience if I go very briefly over the provisions of the Bill, to which I ask your lordships to give a first reading. The principal object of the Bill is to require the person registered in the *Medical Register* to have both a medical and a surgical qualification. At present, there is only a single qualification; but, for the future, there will have to be a medical and a surgical qualification. Secondly, the Bill will allow the registration of foreign and colonial practitioners. I will point out how that is done as I go on. Thirdly, the measure will restrict the assumption by unqualified persons of designations implying qualification. The state of the law on this subject is not satisfactory, as some persons designate themselves physicians when they have no right to do so. Fourthly, the Bill will make further provision for securing uniformity of qualification in the United Kingdom. Fifthly, it will make provision for women similar to that intended to be made by the 33 and 34 Victoria, chap. 41, commonly called "Russell Gurney's Act". Sixthly, it contains a provision for the examination and registration of dentists and midwives, and it also amends the Act of 1858 in the matter of registers and deals with the subject of lunacy, qualification of medical officers on colonial ships, and other matters. The alteration of the Register is an important function. If it is to be done by the Medical Council or a Committee, it is a very important duty to entrust to any one to strike off the Register persons who have no right to be there. As to the mode in which these various heads are to be carried out, the third clause will prevent a person from being registered in future unless he has obtained a diploma for medicine and one for surgery from

the medical board established under the Act. If it should happen that a person in England should be examined under the Conjoint Board, that would give him a double qualification; but, if the person be in Scotland, then he would require to have two diplomas: one from the Board of Physicians and the other from the Board of Surgeons. The Act will not apply to persons registered at the time of its passing. It is not to be a retrospective Act, but one to deal with the future. Three clauses which follow those to which I have referred enable a person who has obtained a medical diploma entitling him to practise in a colony or foreign country to be registered on proof being found of good character, and if the diploma be one recognised by the Medical Council as a diploma representing a degree of knowledge attested by an examination equal to that which is necessary in the case of those who practise in the United Kingdom. If the Medical Council refuse to grant a licence to either of these persons—the colonial or the foreign practitioner—then there is an appeal to the Privy Council by the party who may think himself aggrieved. The next clause requires that the colonial and foreign practitioners shall be entered on a separate list or register distinct from that kept for the United Kingdom. Another clause requires the Medical Council to exercise the power of striking the names off the *Register*, or restoring them when necessary. As this proceeding will be of a very critical character, it has been thought that it could be more safely entrusted to a small committee than to a large body of the Council. Then the next clause of importance is one which extends the power which the General Medical Council possesses at present of superintending and examining medical diplomas, and allows them, with the approval of the Privy Council, to make rules for the purpose after the passing of the Act. These rules are to be made subject to two important provisos. The first is with regard to the admission of women; namely, that a medical authority, who is now not bound and does not examine women, shall not be compelled to do so hereafter; and the second is, that rules shall be made so that women shall not be compelled, if they object, to pass the same examination as men. These examinations are the only means by which persons can, under the provisions of the Bill, enter the profession; and, as the Bill makes the law against unregistered practitioners very strict, I thought it only right that the examination should be subject to some general control. The Privy Council, therefore, is entitled to control if the rules in the examination shall be considered to be unduly objectionable. The next clauses are those which give the medical authorities power to combine for the purpose of conducting a joint examination. With regard to women, it is provided that the obtaining of one of the diplomas shall not entitle any person to any right in connection with the medical corporations. That is to meet the difficulty which has arisen under Russell Gurney's Act, where, practically, women are excluded from being examined. Then the second paragraph of Clause 20 effects the intention of Russell Gurney's Act. Clause 21 is to effect what has already been effected in the case of the University of London, the College of Surgeons, and the Society of Apothecaries by their special Acts, which enables them to remove any obstacles to providing joint schemes of medical boards which arise from any of their Acts or Charters. This clause is to make the matter perfectly clear. The next clause (22) is one which enlarges very much the provisions of the Act of 1858 dealing with the assumption by unregistered persons of designations which imply that they are duly qualified practitioners in medicine and surgery. It does not—for that would be impossible—attempt to prevent unregistered persons from practising, but it prevents persons from assuming certain designations, or it imposes a penalty on persons who, for purposes of gain, assume certain designations to which they are not entitled. The clause contains some saving powers in respect of midwives and dentists. Private individuals are restricted in their rights of prosecution without the consent of the authorities. Unless they have the consent of the Medical Council, they cannot prosecute. The next clause, which is an important one, enables the Medical Council, with the consent of the Privy Council, to arrange for the examination, licensing, and registration of dentists. The clause requires them to enter in any register which is made the existing practitioners and also foreign and colonial dentists. Your lordships will, no doubt, be aware of the measure brought in the other House of Parliament to deal with the subject of dentists. I have had the advantage of seeing and consulting some of the most eminent practitioners in this country, and I may say that, though that Bill is not altogether satisfactory, I hope the present Bill will carry out mainly what the promoters of that Bill had in view, but carry it out, if I may say so, in a better manner. The Bill provides that no person shall assume the designation of dentist, or any designation signifying that he is qualified to practise dentistry, unless he is on the *Register*. This will avoid some of the objections to the measure in the other House of Parliament. Then the Bill goes on to deal with another important question, on which I

have had many communications; namely, the subject of midwives. This is a matter which we must all admit is of the greatest importance, but it is also a difficult question to deal with in anything like a stringent or a strict manner. I think all we can do is to indicate the best mode of proceeding in the matter, and I hope that by degrees we shall raise the status of midwives and improve their education, and let the people of the country see that there is an advantage in employing those who have passed a certain examination. Clause 24 requires the *Register* to include existing practitioners; but it does not touch foreigners or colonists. It enables local authorities to undertake at their own expense the duties of examining and registering, and it provides that no persons, unless they have passed the examination, shall be entitled to call themselves registered midwives, which would be the title of the persons who had passed the required examination. The twenty-ninth clause is intended to encourage those who have only a single qualification to obtain a double qualification. It was taken from the Bill introduced several years ago by my noble friend opposite, and I believe it will have a beneficial effect. I ought to mention that there are clauses in the Bill which touch the Lunacy Acts, and that I have thought it right, as your lordships may well imagine, to send these clauses to the Lunacy Commissioners, to ask their opinion as to the wisdom of passing them in the form in which they now are. The Lunacy Commissioners have informed me that they are not altogether satisfied with the clauses as they stand in the Bill. I have thought it better to leave them in the Bill as they stand, because I have not received any amendments from the Commissioners. Of course, when I do receive the amendments, I shall insert them in the Bill, to meet the views which may be entertained by the Commissioners. Then there is a provision for allowing persons who have been properly examined and registered in the colonies to practise and hold positions on board colonial ships. I think, my lords, these are briefly some of the more important provisions which I propose to deal with in this Bill. The matter is one of very considerable importance. It is a question which, I think, your lordships will all admit is very complicated and complex in its character. It is one that requires very great consideration. It is one which ought not to be hastily legislated upon, and I should hope, by postponing the second reading of the Bill for some time, to get the benefit of all persons in the country who are interested in it, and who are competent to give advice in the matter. I need not add, I think, that I shall be ready to give the most attentive consideration to all suggestions which may be made with a view, if possible, of passing a good and useful measure. My lords, I do not think I should be justified in trespassing longer upon your time in introducing the measure. It is one which is best seen in the perusal of the clauses as they stand in the Bill, and I shall now content myself by asking you to give the measure a first reading. [*Hear, hear.*]

THE MARQUIS OF RIPON: My Lords, I do not rise for the purpose of entering into a criticism of the measure the noble Duke has proposed, for I agree with him that it is a Bill which we shall be much better able to consider when we have it before us. I know the difficulty of dealing with this question, as I had charge of a Bill relating to it in 1870, which this House was good enough to pass, but which did not successfully pass the House of Commons, on account of the opposition of certain gentlemen who were anxious to obtain direct representation. I am glad the measure proposes to do away with what is called half qualification, and will require all persons for the future to be qualified both in medicine and surgery, and I am also glad that the measure proposes to make further arrangements with respect to the registration of foreign candidates, which is most desirable. But as my noble friend has invited the consideration of the subject, I must confess that I cannot but express my regret, if I rightly understand the explanation of my noble friend, at the exceedingly permissive character of the Bill. It will secure for England a single examination provided a conjoint Board is appointed. But, unfortunately, if it should be wrecked, as it has been on previous occasions, I do not see that there is in the Bill, as there was in that of 1870, any power to provide, by legislative enactment, for the failure of existing bodies to agree to the constitution of a conjoint board. I will only say this, that I believe the one thing which is most important in this matter is that you should provide that for the future, at all events for each of the three kingdoms, there should be but one portal to the medical profession, and that you should shut the nineteen doors by which you can at present get to it. If my noble friend does not secure that by his Bill, I am sorry for it.

The Bill was then read a first time.

THE DUKE OF RICHMOND AND GORDON: I propose to ask your Lordships to read the Bill a second time on Monday, the 15th of April.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### "A CONSTITUTIONAL QUESTION."

SIR,—Breach of faith towards medical officers makes all public services unpopular. It is breach of faith to violate the laws of the land and particular contracts by depriving medical officers—I beg pardon, servants—of their legitimate dues. The law compels medical servants to attend at once, without orders, urgent and dangerous cases. Such cases are attended to under pain of a reprimand from the coroner and dismissal from office; yet for the first time Guardians can refuse to pay, stating that the medical servant must attend "on spec." He is to procure the fee from the already underpaid agricultural or other labourer. A dangerous case of flooding was attended by me three miles from my residence. The Guardians refused an order, and I could not gain my fee of £2, although the well entitled parties complained to the London Local Government Board. I prosecuted the labourer in the County Court. The influence of the Local Board was manifest there; and, after a year or so, the fee of £1 1s. was ground out of the poor labourer. Do you, sir, not think that if the Guardians refuse to give orders, medical servants have a right to refuse to attend? They are compelled to be brought into conflict with the Guardians and the patient sufferer.

I enclose you an order received to day to attend, a month after labour, a woman likely to require a pessary; the Guardians having refused the distressed husband an order previous to his wife's confinement. I should have been compelled to attend on spec., or be liable for manslaughter. Surely, sir, the worst paid ministers of the poor—I mean the Poor-law medical officers—require protection; and it is in their interest I write, as it has pleased God to provide me with private means beyond their control. Without this I could not live, as my salary is more than swallowed up by Poor-law medical expenses. Moreover, the Poor-law doctor experiences further breach of faith by the discovery that he is ostracised from private practice. He finds the extortionate exactions upon his time, medicines, horses, price of necessities of life, and other matters, weigh him down. Millers, doctors, and brewers were lately told they ought to pay all expenses for the maintenance of roads. The Bible tells a Christian land to bear one another's burdens. Now, the medical expenses of this country amount to the comparatively small sum of six millions only, as shown by the recent returns of this week, and other expenses not medical inclusively make the total about thirteen millions. [The income of the country is at least three hundred and seventy millions.] This is a paltry sum for these most necessary and useful expenses, making up as they do largely for deficiency in wages; but it is only fair to say that a peasantry who can afford to waste one hundred and sixty millions a year in drink should provide for their own medical requirements. Till this is done, and by whatever means we are paid, we should at least be protected.

I must say, also, that I acknowledge relief by the self-supporting dispensary system; but when extra fees, amounting to about £40 a year, are almost completely cut off, and we have to do heavy sanitary work for only £20 a year, we are at a loss, financially and in every other respect.

The woman I have to attend is likely to require a pessary. Is it my duty to provide one? [A record of similar flagrant cases is desirable.] I complain, sir, that the medical servants of the poor are not allowed sufficient pay, upon the ground that they are properly paid, the contrary fact being well established; neither will the civil authorities allow public subscriptions for the benefit of poor medical ministers.—I am, sir, yours obediently,

RUFFLEO.

March 2nd, 1878.

### CERTIFICATES FOR IMBECILES IN WORKHOUSES.

SIR,—Can you or any of your readers inform me whether I am entitled to charge 2s. 6d. for signing the quarterly certificates of each of the imbeciles that are in the union-house, I being the medical officer to the union-house and district?—I am, yours truly,

A. J. A.

\*.\* The medical officer of a workhouse is prohibited from charging a fee of 2s. 6d. for certifying the fact that there is a harmless lunatic who may be legally detained in the house. Such quarterly return forms part of his official duty. The fee is strictly limited for visiting a pauper lunatic or imbecile not in a workhouse or licensed asylum.—Ed. B. M. J.

### PUBLIC HEALTH EXAMINATIONS: LONDON OR CAMBRIDGE.

Will any gentleman who has been up for either of these examinations kindly say what books are most suitable for the necessary reading, where some practical instruction in chemical inquiries can be obtained, and add anything more that may help to guide?

A CANDIDATE.

### REPORTS OF MEDICAL OFFICERS OF HEALTH.

MERTHYR.—The medical officer, Mr. Dyke, reported that the birth-rate for the district during the quarter ending December 31st was 34, and the death-rate 16.5, per 1,000 inhabitants; that the mortality from contagious diseases amounted to 11 per cent. of the total deaths; but there were only four deaths from typhoid. He also briefly reported the vital statistics for 1877, which show that the birth-rate was 37 and the death rate 21 per 1,000; the mortality of children under five years being 45 per cent. of the whole. There were 66 deaths from tubercular disease, 38 from convulsions, 86 from inflammatory diseases of the lungs, and only 30 from zymotic diseases.

LINCOLN RURAL.—Dr. Harrison reports 821 births and 455 deaths in this district during 1877, of which 8 deaths were caused by typhoid.

About 12 per cent. of the deaths were caused by phthisis, 17 per cent. from bronchitis, and only 8 from diarrhoea. The death-rate was 17.8 per 1,000 including all deaths in the county asylum, and 14.7 after excluding them. The by-laws as to new buildings were being strictly enforced even in the small villages, and cases of overcrowding discovered had been abated, as well as other nuisances. The drinking-water from wells was bad.

CREWE.—The death-rate during the quarter ending December 31st was 17.6 per 1,000 *per annum*. Dr. Lord also reports 7 deaths from typhoid, 4 from scarlet fever, and 1 from typhus; and objects to rheumatism and several other diseases being classed with zymotics. The largest number of deaths was caused by bronchitis, tubercular diseases, and convulsions. He considers that much injury to health is caused by vegetable matter being thrown into the cesspools with the night-soil, and from stoppage of the drains. He also reports that the medical men of the town will in future report to him the existence of cases of zymotic disease.

WANDSWORTH.—The population was estimated at 153,648 in the middle of 1876. There were 5,999 births and 3,154 deaths registered in the district, which give a death-rate of 20.5 per 1,000 population, which is considered to be too high, as the population is probably larger than the estimated number. This district is made up of the following subdistricts; viz., Battersea, in which 3,459 births and 1,745 deaths were registered in 1876; Wandsworth, in which 679 births and 461 deaths occurred; Clapham, in which 1,029 births and 545 deaths were registered; Streatham and Tooting, in which there were 536 births and 260 deaths; and Putney, in which 300 births and 143 deaths were registered. The proportion between the births and deaths in the Putney district was somewhat unusual, there being more than 200 births to 100 deaths. Measles and scarlatina prevailed to a great extent; and small-pox was also prevalent, especially in Clapham. The epidemic death-rate varied between 4.8 per 1,000 population in Battersea and 1.7 in Putney, having been 2.8 in Clapham. The mortality amongst infants was large; viz., 43.3 per cent. of the total deaths. The water-supply is said to be bad, and the want of a hospital for infectious diseases is mentioned as one cause of the spread of small-pox. The sanitary work appears to have been actively carried out, as 5,929 houses were inspected, and 2,773 drains connected with the sewer.

WHITECHAPEL.—The number of births registered in the district during 1877 was 2,751, and of deaths, including 567 non-residents, 2,506, which give a death-rate of 25.2 per 1,000, which is in excess of that in the previous year by 1.3 per 1,000. If, however, the deaths in extraneous hospitals be added on, the death-rate would be at least 26.2 per 1,000, or, eliminating all deaths in hospitals, 23.2. The estimation of death-rates in districts having large hospitals within their limits is a somewhat disputed point; but it is clear that in such a district as Whitechapel the proportion of deaths in hospitals must be much greater than in rich parishes, and Mr. Liddle's estimated death-rate too low. There were 48 deaths from small-pox in the year, including 25 in the Homerton Hospital, which do not appear to have been included in the registered deaths; but it is difficult to be certain on the matter, owing to the indefinite wording of the report. But the deaths from zymotic diseases, including those in hospitals, are returned at 12.5 per cent. of the total mortality. The table of sanitary work performed shows much energy on the part of the medical officer and inspectors.

NEWBIGIN.—Dr. Reid states that the death-rate for the last quarter of 1877 was the smallest he had ever recorded, there being an almost total absence of zymotic diseases and a low rate of deaths from all other causes. He expresses his regret at the want of proper cottages for the poor, and instances the death of an infant which he believes was caused by the extreme dampness of the room in which it was born and the emanations from the mouldy paper on the walls. He also reports the want of proper drainage for some cottages, and the bad state of the road leading to the sands.

BIRMINGHAM.—During the quarter ending December 23rd, Dr. Hill reports that 3,927 births and 2,284 deaths were registered, giving a birth-rate of 41.6 and a death-rate of 24.21 per 1,000 *per annum*, which was in excess of that for the corresponding period of 1876. The excess of mortality was chiefly owing to diseases of the respiratory organs, measles, and whooping-cough. The mean temperature for the quarter was 45.5 deg. Fahr., against 46.2 deg. for 1876, but 2.5 deg. above the mean of the same period for ten years. The mortality from zymotic diseases represented an annual rate of 4.75 per 1,000, against

3.0 in 1876. Dr. Hill examined as many as one hundred and fifty-nine samples of well-water, and gives a table of the results, showing that in nearly every instance the water was unfit for use. The amount of sanitary work performed was large, and a great quantity of meat unfit for food was destroyed. Thirty-five articles of food, drink, and drugs were examined, of which nine were adulterated; viz., four of gin (watered), four of precipitate of sulphur with sulphate of lime, and one of pepper with sand.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, March 14th, 1878.

Collins, George Duppa, King's College Hospital  
Diggle, John Arthur, Stretford Road, Manchester  
Pylus, John Alfred, Godalming, Surrey  
Smith, Herbert Arthur, Havercroft Hill  
Webster, Ridley Manning, Colebrooke Row, Islington  
Wood, Charles, 38, Trinity Square, S.E.

The following gentlemen also on the same day passed their primary professional examination.

Hackman, L. K. H., St. Mary's Hospital  
Mennell, Zebulon, St. Thomas's Hospital  
Veale, William Edward, St. Bartholomew's Hospital

**UNIVERSITY OF DUBLIN.**—At the Spring Commencement, held on Shrove Tuesday, March 5th, 1878, the following Degrees in Medicine and Surgery were conferred by the University *caput*.—Bachelors in Surgery.

Daly, Ulysses A.  
Fogarty, Thomas F. W.  
Mallins, Clement

White, Edward W. W.  
Young, Alexander G.

**Bachelors in Medicine.**

Cox, Henry L.  
Cowen, Edward J.  
Egan, Constantine R.  
Daly, Ulysses A.  
Dey, James D.  
Malley, Abraham C.

M'Cullagh, James A.  
Neville, William Cox  
Pentland, Alexander  
Rockliffe, W. C. (*ad eund. Cantab.*)  
Tench, Charles H.  
Young, Alexander G.

**Masters in Surgery.**

Hurford, Cedric H.

Taylor, Rogers W. C.

**Doctors in Medicine.**

Alexander, James  
Cosgrave, Ephraim M.D.  
Gibson, George

Irwin, John A.  
Rockliffe, William Craven

## MEDICAL VACANCIES.

**THE** following vacancies are announced:—

**ALICE DALE INFIRMARY,** Cape Colony—Obstetric Physician. Salary, £500 per annum, with house, servants, and horse. Applications to be made on or before May 1st.

**BALLINASLOE UNION**—Medical Officer for Kiltormer Dispensary District. Salary, £112 a year, and £15 yearly as Sanitary Officer, together with registration and vaccination fees. Applications to the 25th instant.

**BIRKENHEAD BOROUGH HOSPITAL**—Junior House-Surgeon. Salary, £60 per annum, with board and lodging. Applications to be made on or before the 25th instant.

**BLACKPOOL,** Borough of—Medical Officer of Health. Salary, £100 per annum. Applications to be made on or before the 27th instant.

**BRISTOL GENERAL HOSPITAL.** Physician's Assistant. Salary, £50 per annum. Applications on or before April 19th.

**CERNE UNION**—Medical Officer of Health. Salary, £60 per annum. Applications on or before the 25th instant.

**LANCASTER INFIRMARY AND DISPENSARY**—Salary, £120 per annum, with apartments, coals, gas, and attendance. Applications to be made on or before April 3rd.

**LURGAN UNION**—Medical Officer for Aghalee Dispensary District. Salary, £100 per annum as Medical Officer, and £16 yearly as Sanitary Officer, with the usual registration and vaccination fees. Applications to the 25th instant.

**MANCHESTER ROYAL INFIRMARY**—Resident Surgical Officer. Salary, £150 per annum, with board and residence. Applications on or before the 31st instant.

**NARBURTH UNION**—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.

**QUEEN'S HOSPITAL,** Birmingham—Honorary Physician. Applications to be made on or before April 13th.

**ROYAL UNITED HOSPITAL,** Bath—Resident Medical Officer. Salary, £100 per annum, with board and lodging. Applications to be made on or before the 30th inst.

**STAFFORD HIRE GENERAL DISPENSARY**—House-Surgeon and Secretary. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 26th instant.

**WEST SUSSEX, EAST HANTS, AND CHICHESTER GENERAL INFIRMARY AND DISPENSARY**—House-Surgeon. Salary, £80 per annum, with board, lodging, and washing. Applications on or before the 30th instant.

## MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

\*BARLOW, Wm. H., M.D., appointed Consulting-Physician to the Dispensary of the General Hospital and Dispensary for Sick Children, Manchester and Pendlebury.  
\*BERDOE, E., L.R.C.P.E.D., appointed Surgeon in Ordinary to Queen Adelaide's Dispensary, London, vice G. P. Bates, M.D., resigned.  
HOLLAND, Lucius, M.D., appointed Aural Surgeon to the Newcastle-upon-Tyne Dispensary.

## BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.*

### BIRTH.

RENDALL.—On March 13th, at Maiden Newton, Dorsetshire, the wife of William Rendall, M.R.C.S., of a daughter.

**PNEUMONIA AND EPIDEMIC DISEASES.**—At a recent meeting of the Epidemiological Society of London, Dr. William Squire read a paper on the relation of pneumonia to epidemic diseases. He said that pneumonia is not specially a disease of cold weather or of cold climates; like phthisis, it occurs with greater proportional frequency among dense populations; but, unlike phthisis, the mortality is not evenly distributed throughout the different months of the year. Nor does the seasonal mortality from pneumonia correspond with that for bronchitis, which increases in cold times and places, but follows a course very similar to that for some epidemic diseases. In northern towns, many cases of bronchopneumonia in the very old and very young are included in the pneumonia returns, making them higher in the winter than in the spring; laterly, with more precision in the diagnosis, we find a progressive increase in the returns from bronchitis, with the highest mortality in January; and a decrease in returns for pneumonia, the greatest mortality occurring always in the spring. Among epidemic diseases, small-pox and whooping-cough are found invariably to have their greatest increase in their spring. Scarlet fever as invariably increases at the end of summer, and is most fatal in the autumn. Measles has both a summer and winter recrudescence. Enteric fever is an autumn epidemic, and not coincident with pneumonia. It was with typhus and not with enteric or typhoid fever that von Ziemssen associated pneumonia; their decrease in London, as noticed by him, coincided with the enforcement of the Common Lodging House Act; but typhus prevails without pneumonia and pneumonia without typhus. The diseases which correspond more nearly with pneumonia are puerperal fever, erysipelas, quinsy, and croup. The pneumonia, frequently fatal after measles, and which complicates whooping-cough and diphtheria, is of the catarrhal or secondary kind; this should be considered as part of the diseases it complicates; it has no appreciable influence on the pneumonia returns. Acute primary lobar pneumonia is, according to the author's experience, not rare in children; part of the large infantile mortality from pneumonia may be fairly attributed to it. A marked difference between the acute primary pneumonia and the secondary or catarrhal form is found in the temperature chart of the two diseases, constructed from numerous cases of both kinds at all ages. In catarrhal pneumonia, three, four, or more days of moderate fever lead to a central peak of 103 deg., or rarely 104 deg., and never long maintained at that point, but subsiding as free expectoration is formed. True pneumonia commences with a temperature of 103 deg., even on the first day of chill, and before the local signs of the disease are distinct; the temperature then rises suddenly to 104 deg. or to 105 deg., and is steadily maintained at or near this height, with no marked evening exacerbation, for six or seven days, and then descends by two steps to the normal, the first descent preceding any marked improvement in the lung. This typical temperature course is found equally in sthenic and asthenic cases, whether produced by foul air or by chill, in children of from one to five years of age, as well as in adults. It is not necessary to assume a specific poison for pneumonia because of this marked course; the definite duration, the cessation of the general febrile disturbance before the subsidence of the local mischief, and the tendency of that to disappear after the febrile stage is over, are all found in diseases not brought about by an infecting germ. Nor is the difficulty of producing pneumonia by direct irritants, as in the experiments of Heidenhain, a sufficient reason for such assumption; the changes noted in the lungs by Friedländer after section of the vagus and recurrent nerves has a closer bearing on the subject. Many conditions of fatigue, chill, malaria, and constitutional change may lower nerve-tone and predispose to an attack of pneumonia. In its tendency to affect some persons more than others and to recur, it resembles erysipelas; both are found in local outbreaks associated with circumstances of defective hygiene. All these considerations remove pneumonia further from the local inflammations, and correlate it with the general diseases more directly under the influence of conservative medicine.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.**—Medical Society of London, 8.30 P.M. Drs. Manson and Cobbold, F.R.S., "On Filaria Sanguinis Hominis clinically considered in reference to Elephantiasis Chyluria and Allied Diseases (with specimens)."

**TUESDAY.**—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. George Thin, "On the condition of the Skin in Tinea Tonsurans"; Mr. Laidlaw Purves, "On Paracetosis of the Tympanic Membrane"; Dr. Southey, "On the Minute Anatomy of the Kidney as bearing on its Physiological Functions."

**WEDNESDAY.**—Hunterian Society, 8 P.M. Mr. J. E. Adams, "On some rare forms of Iritis." Other members will bring forward cases.

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 35, Great Queen Street, W.C., London.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

## THE BARTER FUND.

SIR,—I beg to acknowledge with thanks the following contributions to the fund.

Cesar Hawkins, Esq., London .. .. .	£	s.	d.
Dr. Barr Meadows, London .. .. .	..	..	5 0 0
T. Corbett, Esq., Kingston-on-Thames .. .. .	..	..	1 1 0
F. E. A. .. .. .	..	..	1 1 0
Further subscriptions are urgently needed.	..	..	0 5 0

Latham House, Crickhowell, March 19th. PHILIP E. HILL.

## GLAUCOMA.

SIR,—The information which Mr. Wilson Hope requires appears to be the *modus medendi* of the operation of iridectomy as curative of the above disease. It is not by setting up inflammation in a secreting membrane, but by establishing a drainage between the posterior chamber and the subconjunctival areolar tissue, and thus relieving tension.—Yours faithfully,

London, March 16th, 1878. ALFRED E. BARRETT, M.R.C.S. Eng., etc.

WILLIAM CAMPBELL, described as the heaviest man in the world, is exhibiting himself just now in the Egyptian Hall. He stands 6 feet 4 inches in height, and weighs over 52 stones. He measures round the shoulders 56 inches, round the waist 28 inches, round the calf of the leg 35 inches. He is twenty-three years of age, and is the second son of a family of seven children of ordinary proportions. His father was of average weight, although 6 feet 2 inches high. His mother was under the average height, and not stout.

## SEVERE YOWITIN.

SIR,—I advise your correspondent "M.R.C.S." to administer every two or three hours one minim of terebene suspended in one or two drachms of mucilage. All stimulants should be avoided, and the lower bowel should be kept clear by means of enemata. I have seen excellent results from this course of treatment.—Yours truly,

Macclesfield, March 18th, 1878. B. Z.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**ADVERTISERS** are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the *JOURNAL* Office or any stated address other than a Post Office.

## LADY-MEMBERS OF THE ASSOCIATION.

SIR,—To prevent misunderstanding, will you give me a few lines of reply to Mr. Henry Brown's letter in your *JOURNAL* of the 15th instant: His reading of the laws of the Association is very confident, but to me in no way convincing. Wrong he assuredly is, when he says that the Committee of Council can at their pleasure expel me or any member. They cannot do so without assigning due and sufficient reason for their action, such as will stand the test of their own laws, and of a court of law. Moreover, until sufficient legal authority determines otherwise, I shall hold to the opinion that neither can the Committee expel duly elected lady-members merely because they are of the so-called weaker sex. The law says that "any qualified medical practitioner" (it does not say medical man) "may be elected, etc." Lady-practitioners may, therefore, clearly be elected in accordance with the letter, if not with the spirit, of the law. The interpretation of the law, as being exclusive of females, by the light of the words *he* and *his* in other of the laws, on which Mr. Brown lays so much stress, would properly be regarded by lawyers as valueless. We all know that the female is constantly included under the nobler *he* and *his* in general rules of common life; and it is so from one end of the Bible to the other. Every railway time-table tells you that the passenger shall "deliver up his ticket", and so on. The lawyers read laws as they stand; and in this case will ask why, if they were meant to exclude females, did the framers of them write down "practitioners" instead of "men". It would be no answer to say that they were so meant. There ought to be no ambiguity on the subject, and there evidently must be until the laws are altered. I may add that if my views of the laws are wrong, I err in very good company. If Mr. H. Brown be right, the Committee of Council committed a very patent blunder, and, in fact, broke the laws when they admitted lady-members; and have, moreover, ever since tacitly permitted the infringement of the laws in not electing the ladies from the Association. I cannot doubt that the Committee find themselves powerless in the matter; and I would again venture to express the hope that the Association, considering all attendant circumstances, will not attempt any arbitrary exclusion of these ladies. The Association, rightly or wrongly, admitted them. The ladies are *de facto*, and, I believe, *de jure*, members of it, and it would ill become this great body of medical men to punish others for the consequences of their own act. By interfering with these ladies as members of the Association, the profession will surely be subjected to the reproach of the public, and in my opinion, for once in a way, to their well deserved reproach. What more in reason can any member ask or desire than the passing of a law which shall in future prevent the recurrence of a fact that weighs so heavily on his conscience?—Yours obediently,

March 15th, 1878.

W. O. MARKHAM.

SIR,—Mr. Brown comes down rather severely on Dr. Markham for not having consulted the by-laws of the Association before having written his moderate and sensible letter on the above subject. Although Mr. Brown has taken up nearly a column of your space in discussing the right of Mrs. Haggan and Mrs. Anderson to be considered members of the Association, on the ground that the by-laws on this subject only use the word *he* in reference to membership, he appears to be quite unacquainted with the fact, that it has been ruled over and over again in the law-courts, that wherever the word *he* can, by the circumstances of the case, be considered to include females also, it must be taken to do so, unless they are excluded by distinct provision. His contention, therefore, falls to the ground, and the ladies in question are as legally members of the Association as Mr. Brown himself is.

Really, sir, when one hears all this terrible uproar and indignation created by the admission of two solitary females amongst a constituency of some five thousand or six thousand men, one feels inclined to ask whether the subject is not too ludicrously contemptible to be worth the space it occupies in your columns.—I am, etc.,

FRANCIS T. BOND, M.D.

DR. R. H. TAYLOR will observe that it was proposed by the Committee of Council, at their last meeting, to pass a by-law of the kind which he suggests; and the question of the best method of dealing with the two ladies in question is referred to a special general meeting in Birmingham. The by-laws of the Association provide ample means for taking steps that these ladies shall cease to be members, provided such is the wish of the Association.

The following communications have been handed to the General Manager:—Mr. J. Moulding, Liverpool; Mr. F. W. Hodder, Mhow, Bombay; Mr. R. T. Morgan, Cricklade; Mr. J. Mottram, Norwich; Dr. Garrod, London; Dr. F. J. Levinge, Stapleton (with enclosure); Dr. John Reddoe, Clifton; Mr. Wm. Maycock, Leamington; Messrs. Reed and Wayman, Downham; Mr. James Dickson, Bootle; Mr. Wm. Rendall, Maiden Newton (with enclosure); Mr. Hatten, Bolton.

MR. HENRY M. CRANCE'S letter shall appear next week. The idea is an excellent one, and we shall be glad to give it all the help in our power.

## AN EASY METHOD OF PLUGGING THE POSTERIOR NARES IN CASES OF

## HEMORRHAGE.

SIR,—As I believe that more or less trouble and difficulty are generally experienced in using either Bellocq's cannula or the ordinary catheter, as usually directed, I would beg to call attention to the following plan, which I find to be both extremely easy as well as rapid of performance. Provide two soft (commonly called worm) catheters, and with scissors remove the end containing the eyelet-hole; then, by means of a long wire or needle, thread each with a double ligature. Pass one through each nostril well into the pharynx. Dangling loosely here, it is easily drawn through the mouth by passing the forefinger around it. The catheters having been removed, either through the nose or mouth, the plugs are tied and drawn back. It is better to use a catheter for each nostril before attempting to plug, as I have found that when the first plug is in position, the catheter did not pass so readily through the other nostril.—I am, etc.,

March 14th, 1878.

F. T. FRANKLAND.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### THE TEACHING OF MATERIA MEDICA.

SIR,—Your correspondent Mr. C. M. Jessop, writing from Clifton, seems to have peculiar ideas about what qualifications constitute the best physicians and surgeons. There is no doubt such a multiplicity for the medical student of this present day, that any proposal which would simplify and systematise his work should be examined with great attention. In the main, I quite agree with Dr. Farquharson's remarks, and think that if the general operations of drugs and their doses are well known, the remembrance in most cases of the minutiae of preparations might surely be dispensed with. An exception to this rule might be made as to those drugs which are more immediately toxic in extended doses, and a comparatively intimate acquaintance with such required. The first years of a student's life are really of the first importance, that he should carry on his habits of education which we presuppose he has acquired. I entirely doubt that work in a surgery or a chemist's shop is likely to foster these; but such questions as these may in great measure be left to the Medical Council and teachers in our schools. I opine that it is not desirable that a youth of very immature judgment should learn by rote various modes of prescribing. Prescribing should be adapted to each case of disease, and a distinct reason be assignable for every part of a prescription.

It strikes me that Mr. Jessop is very unhappy in his selection of two prescriptions as incompatible—one, a mixture of dilute hydrocyanic acid with dilute nitromuriatic acid; and another, "quinine mixture in a mineral acid solvent with Fowler's solution". Now I fail to see the slightest incompatibility in either of these mixtures. In the first, chemically, there is no change; therapeutically, the effects are the same as far as the hydrocyanic acid is concerned, whether it is given simply in water, in water acidulated with a mineral acid, or whether it is given as cyanide of potassium. Why is this so? It is simply that in each of the first-named cases the hydrocyanic acid is in a free state; in the last case, the hydrocyanic acid is set free in the stomach by the acid there, or if it reach the blood in a combined state, the free carbonic acid of the blood liberates it. Donovan recommends an eighth of a grain of cyanide of potassium, with some syrup of lemons, as a substitute for hydrocyanic acid. Sir R. Christison distinctly states that those specimens of dilute hydrocyanic acid keep best in which there is a trace of free mineral acid. Now, as to the second prescription mentioned by Mr. Jessop, Fowler's solution in a quinine mixture, with a mineral acid as a solvent; I thought it was generally allowed that the various preparations of arsenious acid were dependent on the proportion and solvency of acid (arsenious) that they contained, rather than the manner in which it was combined (at least as far as the arsenious acid is concerned); and a little reflection should have showed Mr. Jessop that the mineral acid in the quinine mixture merely converted the arsenite of soda in the Fowler's solution into a compound like the liquor arsenici hydrochlor. For many years in India, I saw prescribed and prescribed myself liquor arsenicalis and quinine mixture as an antiperiodic; and I am quite sure that if Mr. Jessop tries this combination, he will get distinct evidence of the therapeutic effect, which, I presume, the aim of prescribing.—Your obedient servant, T. M. LOWNDS, M.D., Surgeon-Major (Retired) H. M. Indian Army.

Egham Hill, March 9th, 1878.

SIR,—Having lately had occasion to prescribe nitro-muriatic and prussic acids in mixture, I am sufficiently horrified to-day to find, on the authority of Mr. Jessop, that I had in all probability been laughed at by the chemist who dispensed it. Will Mr. Jessop kindly inform me, through the medium of your JOURNAL, why he considers such a mixture incompatible? On turning to written authority, I find such a mixture more than once recommended in Tanner's *Medicine*. Dr. F. Roberts mentions them as being useful in chronic alcoholism, and another author remarks that incompatibility may be "therapeutically ideal". Led by these authorities, I am emboldened to add that in my particular case the treatment was not incompatible with the patient's improvement.—I am, etc., L.R.C.P. Edinburgh, March 9th, 1878.

#### THE DEGREE OF M.D. BRUSSELS.

SIR,—In reply to the question on this subject in last week's JOURNAL, I should recommend the following books: Eryant's *Surgery*, Taylor's *Medical Jurisprudence*, Gray's *Anatomy*, Kirke's *Physiology*, Green's *Pathology*, and Churchill's *Midwifery*. For full particulars of the examination, etc., at Brussels and other Continental Universities, I should recommend your correspondent to obtain the *Guide to European Universities*, which has just been published, and was advertised in the BRITISH MEDICAL JOURNAL last week.—Sir, yours very truly, M.D. March 17th.

#### CONGENITALLY IMPERFORATE PREPUCE.

SIR,—A parallel case to that described by Dr. Mackenzie of Rugby came under my notice some years back, when I was attending midwifery in connection with the out-patient department of St. Bartholomew's Hospital. The child was well developed, and had no other defect about him. Before leaving the house, I removed the redundant prepuce with scissors, and divided the mucous membrane sufficiently to allow of full retraction, very little hæmorrhage occurring. The urethra itself was natural. On the seventh day, the wound had quite healed.—I am, etc., J. HERBERT SLOWERS, M.D., Physician to St. John's Hospital for Diseases of the Skin.

March 14th, 1878.

MR. HATTON'S (Bolton) letter has been handed to Mr. Fowke, who will, no doubt, be able to give a satisfactory explanation.

#### TURPENTINE IN POST PARTUM HÆMORRHAGE.

SIR,—I have never given turpentine in post partum hæmorrhage, but I can quite understand its value as a stimulant to the uterus in such cases. If administered by the mouth, it must have three disadvantages. 1. It is intensely disagreeable to take; 2. It is difficult to swallow in cases of collapse from excessive hæmorrhage; 3. It is very likely, as Dr. Savage observes, to be rejected by vomiting. Might not all these difficulties be overcome, and the treatment perhaps rendered more effectual, by injecting the drug per rectum?—Yours, etc., GEORGE WELLER. Winstead, March 17th.

W. D. H.—Many thanks. We were not aware of the facts mentioned.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

#### VIGOROUS MIDWIFERY.

SIR,—Philanthropists amongst us have for some time been engaged in the effort to provide the poor with competent midwives, by means of a compulsory system of legislation that would exclude fictitious practitioners. The movement has not yet, I think, made very practical progress. Perhaps the following case that has recently come under my notice may help to show the necessity for some improvement in our present system, or want of system.

I was called on the night of February 8th to go to a woman four miles off, who was reported to be very ill after delivery by a village midwife. I went at once, and found the patient dead. The midwife brought me something in a chamber-vessel, with the remark, "This is what followed the child, sir". I examined it, and found it to consist of the whole uninjured uterus, a small portion of the placenta lying loose in the vessel, but the greater part remaining unremoved and "adherent". There was no portion of the cord attached. I subsequently, by order of the coroner, made a post mortem examination, and found the bladder so lacerated and torn from its position as to be scarcely recognisable, the small bowel torn across, and the mesentery stripped up for eighteen inches of its length. I was informed that all this mischief was the result of an hour and a half's resolute action on the part of the midwife, who silenced peremptorily all suggestions that medical aid should be sent for, and disregarded the piteous appeals of the poor patient for "one five minutes' rest".—I am, etc., HERBERT G. LEE. Thame, February 18th, 1878.

#### UNDERTAKERS' BRIBES.

SIR,—Instead of holding up our hands in virtuous indignation, it would better become us, I think, to fold them in profound humility, at the thought that there are a sufficient number of members of our profession who are, or who are supposed to be, ready to accept a disgusting bribe, to make it worth the while of a touting firm to send out their offensive circulars broadcast.—Your obedient servant, LEONARD W. SEDGWICK. March 17th.

#### HEADACHE.

SIR,—Will any one kindly suggest a cure for headache? The patient is a girl, aged 22, who is a cook. Her general health is in every respect good. She suffers from continual headache, more or less severe, which often awakes her at night. It is in no particular spot, but seems to affect the whole of the head. Among other remedies, guarana has been given, without the smallest good effect. I believe the headache to depend upon the air of Brighton being too exhilarating for her; but as she cannot well leave it, I should be glad to receive hints for the treatment of her case.—I am, etc., J. K.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Courant; The Middlesex County Times; The Liverpool Evening Albion; The Daily Courier; The Kelso Chronicle; The Fifehire Herald; The Merthyr Express; The Carnarvon and Denbigh Herald; etc.

\*. We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

COMMUNICATIONS, LETTERS, etc., have been received from:—

Dr. Ferrier, London; Dr. G. M. Humphry, Cambridge; Dr. Douglas Powell, London; Mr. T. H. Bartlett, Birmingham; Dr. George Johnson, London; Mr. Teevan, London; Mr. R. Harrison, Liverpool; Dr. Joseph Coats, Glasgow; An American Physician, New Brighton, S.I.; Mr. James Moulding, Liverpool; Mr. Ralph Thompson, London; The Secretary of the Sanitas Company; Mr. Callender, London; Dr. T. Eytton Jones, Wrexham; X.; Dr. W. D. Fairless, Rothwell; Dr. Garrod, London; Mr. E. Berdoe, London; Dr. H. J. Hardwicke, Sheffield; Mr. J. Mottram, Norwich; B.; Mr. R. T. Morgan, Cricklade; Mr. C. M. Jessop, Clifton; Dr. W. O. Markham, London; M.R.C.S.Eng.; Mr. N. A. Humphreys, London; Dr. R. L. # THE GOULSTONIAN LECTURES ON THE LOCALISATION OF CEREBRAL DISEASE.

*Delivered at the Royal College of Physicians of London.*

By DAVID FERRIER, M.D., F.R.S., F.R.C.P.,

Professor of Forensic Medicine in King's College; Assistant-Physician to King's College Hospital; etc.

## LECTURE I (concluded).—March 15<sup>th</sup>.

MM. FRANCK and PITRES\* have shown that a distinct interval elapses between the excitation and the movement: an interval which, after deducting the latent periods of nervous and muscular stimulation, and the rate of transmission of neural impulse in the cord and nerves, leaves a residue of nine-two-hundredths of a second of retardation in the grey matter. If, however, the grey matter be removed, and the stimulus applied to the medullary fibres, the period of retardation diminishes to six-two-hundredths of a second. This proves, in accordance with the laws of stimulation of nerve-centres, that the grey matter intervenes, not as a conductor, but as a centre. It has likewise been proved by the experiments of Putnam, Carville and Duret, etc., and verified by Franck and Pitres, that, in order to excite movements after removal of the cortex, a stronger stimulation is necessary than that required for the cortex itself. This, on the physical conduction theory, would be, the less the resistance, the less the effect: a proposition manifestly absurd. It is, however, the property of the nerve-centres to reinforce an excitation; and such is the case with the cortical grey matter. Still more important, perhaps, than these results, is the fact that certain modifications occur in the excitability of the medullary fibres after removal of the cortex, which conclusively demonstrate that we have to deal with neurility, and not with mere electrical conductivity, as Mr. Lewes supposes.

We know from Waller's researches that, when a motor nerve is divided, the excitability gradually diminishes and ultimately disappears: phenomena which proceed *pari passu* with progressive degeneration of the nerve from the centre towards the periphery. In a similar manner, it has been found by Albertoni and Micheli,† confirmed by Dupuy,‡ and by MM. Franck and Pitres, that, after a certain period, excitation of the medullary fibres no longer gives rise to the movements which can be caused by stimulation immediately after removal of the grey matter of the cortex. In dogs, as a rule, as Franck and Pitres have shown, the excitability totally disappears about the fourth day; and this coincides with the period at which, in consequence of the degeneration described, the motor nerves of the dog lose their excitability. By such facts, the only plausible arguments in favour of mere physical conduction of the electrical currents are shown to be absolutely without foundation; and, all other evidence apart, the direct relation of the cortical grey matter to movements is established beyond all doubt.

I have purposely excluded until now the consideration of the effects of localised destruction of the cortex. These, as I hope to be able to show you, are, in the case of man at least, clear and decisive in the same direction. But, it must be admitted, there is a considerable want of unanimity among the conclusions which physiologists have considered themselves entitled to draw from their several experiments. Many of these differences seem to me in a great measure due to narrowness of view, and to the entire disregard of the facts relating to man himself.

We should think it a very misleading research if a pharmacologist were to set himself to determine the mode of action of a drug on the human economy by experiment on an animal, before he had first ascertained whether the animal on which he proposed to experiment exhibited symptoms of being similarly affected by the drug as man himself. Before his researches could be allowed to have any bearing on therapeutics, this would have to be established; for we know that drugs may act differently on different animals. It is even more necessary, in regard to the physiology of the brain, that a similar caution should be exercised. Anatomical homologies must not be pushed too far in support of identity of function.

A frog deprived of its cerebral hemispheres still remains capable of a number of the most complicated and adaptive reactions, so little differing from those normally manifested by this animal that, except for the defect of spontaneity, they might be regarded as identical. But no one will say that the symptoms presented by the brainless frog at all resemble the clinical picture of a case of disorganisation of the cerebral lobes in man. The same may be said of pigeons, the favourite subjects of Flourens' experiments, and the origin of many misleading conclusions in human physiology and pathology. Nor are the phenomena in the case of the much-experimented-on rabbit at all comparable to those observed in cerebral disease in man. We might be led, from the effects of ablation of the cerebral hemispheres in this animal, to regard the cerebral hemispheres as having special functional relation to the upper extremities, as these are more particularly paralysed; and this conclusion has a germ of truth in it, when looked at in the proper light, but is a grave error if applied without qualification to human physiology.

The destruction of the cerebral hemispheres in the dog approaches more nearly in its results to the universal powerlessness caused by a similar lesion in man, but not so complete or enduring. The destruction of the cortex only, however, though at first producing a greater or less degree of paralysis of the opposite limbs, does not render the animal quite powerless; and within a few days or weeks the motor powers are regained to such an extent that, except on hurried movements, a superficial observer might come to the conclusion that the animal had not suffered by the lesion.

Some, who do not extend their view beyond dogs, at once jump to the conclusion that facts like these justify them in asserting that not only in dogs, but in man also, the cortex of the brain has no real relation to motility; and that the phenomena which ensue from cortical lesions are merely transitory disturbances of the functions of other parts. Others, if they do admit any direct relation between the two, assume, from the apparent recovery, that there is no exclusive localisation of function, and formulate a law of functional substitution of one part by another to explain the difficulties, chiefly of their own creation.

When, however, we ascend higher, and come to experiments on animals which in conformation, habits (and shall we say kinship?), most closely approach man, and to the experiments of disease on man himself, we meet with results little in harmony with the conclusions drawn by some from their researches on the lower animals. In monkeys, destruction of those regions, excitation of which gives rise to definite movements of the limbs, causes paralysis of voluntary motion complete and enduring, and restricted to those very movements the centres of which are specially destroyed. It will be my endeavour to show you that what is true of the monkey is strictly true also of man.

Taking these facts as established—the proofs of which will be given subsequently—may we not, instead of trying to contradict one set of facts by the other, find some generalisation which will admit of all these apparently discordant results being harmonised with each other and with the great law of evolution? This, I think, can be arrived at, if we recognise the fact towards which all these experiments on different animals point; viz., that the same movements have a plurality of causes, and are represented, though with different significations, in different centres, higher and lower. Those which involve conscious discrimination, and which we term volitional in the strict sense of the term, are those alone which are necessarily paralysed by destruction of the cortex; while those which are variously described as automatic, instinctive, or responsive, including all the motor adjustments concerned in equilibration, locomotor co-ordination, and instinctive emotional expression, are more or less completely and independently organised in the centres situated below the cortex. Though there is a general solidarity of the whole cerebro-spinal system, yet there exist in different animals great differences in the degree of organisation of such movements in the lower ganglia, and in their relative independence of the higher centres. This is greatest in the frog and pigeon, and lowest in the monkey and man. Hence the marked differences which we observe in different animals in the results of destruction of the cerebral hemispheres.

If we clearly distinguish, therefore, between the different *kinds* of movement and their respective centres, and regard paralysis of truly volitional movements, or those involving conscious discrimination, as the only essential feature of cortical lesions, we shall be in harmony with the results of comparative experimental physiology, and shall not need a hypothesis of functional substitution, which cannot, I think, be maintained consistently by those who accept the doctrine of specific localisation.

In accordance with this generalisation, I ventured to predict that, even in the case of animals whose motor powers did not seem permanently to suffer from destructive lesions of the cortical motor centres,

\* Soc. de Biologie, December 23rd, 1877.

† Sui Centri Cerebrali di Movimento. *Lo Sperimentale*, February 1876.

‡ *Physiology of the Brain*, p. 9.

those movements must be paralysed which involved conscious discrimination, and were not automatically organised. This has been amply verified by Goltz's experiments on dogs.\* Goltz found that, though a dog's paw is not permanently paralysed as an organ of locomotion by destruction of the cortex, yet it remains permanently paralysed for all those actions in which it is employed as a hand.

The conclusion, therefore, which I would provisionally draw from the results of experimental physiology, and proceed to justify by a consideration of the facts of human pathology, is, that there are certain regions in the cortex to which definite functions can be assigned; and that the phenomena of cortical lesions will vary according to their seat, and also according to their character—viz., whether irritative or destructive, two classes into which they may all be theoretically reduced. And, as the experiments of physiology necessitate the strictest topographical accuracy in the position and limits of individual centres, it is of vital importance that the same accuracy should be observed in respect to the situation of lesions in the human brain. For this reason we are, however unwillingly, obliged to discard most of the older records of cerebral disease, unless where supplemented by drawings, or by description of the position of the lesion with reference to certain fixed points; for, although we can now read these cases in the light which laws otherwise arrived at throw upon them, they cannot be used to establish these laws. In the older records, we, as a rule, meet with nothing more exact in the topography of a lesion than that it was situated "on the convexity" of one or other hemisphere, or in the anterior, middle, or posterior lobe—terms which admit of considerable looseness of interpretation. Anatomically, the frontal lobe was generally considered as marked off from the middle lobe by the antero-parietal (Huxley) or precentral sulcus (Ecker); but we find Bouillaud extending the frontal lobe so as to include as much as the half of the hemisphere: an extension of this lobe which may serve to explain his theory as to the seat of the faculty of speech. In the question of localisation of cerebral function, we must follow Bacon's dictum: "*Frustra magnum expectatur augmentum in scientiis ex superinductione et insitione novorum super vetera, sed instauratio facienda est ab imis fundamentis.*"

It is in the observations of the last few years, in which only the necessity of strict accuracy in cerebral topography has been duly recognised, that we must look for our chief material, and of this the largest share has been contributed by Charcot and the French school of pathology. As to the kind of evidence on which we must base our conclusions, I cannot do better than quote and emphasise the injunction given by Charcot and Pitres in their recent valuable papers on the localisation of cerebral disease.† "It is necessary rigidly to exclude as valueless in this relation all observations in which the topography of the lesion is not indicated with rigorous exactitude; and, among those which, in a topographical point of view, leave nothing to be desired, it is necessary to make a selection and reject the majority of the cases of multiple lesions, and all those in which the lesion was diffuse. It is necessary also to accept with extreme caution cases of tumour compressing without destroying the cerebral convolutions; for the effects of pressure may be felt at a distance from the seat of lesion, and complicate the results. In making these estimations, in our opinion absolutely indispensable, the number of ancient observations really available is extremely small; and it is by the aid of new observations, made with all the requisite precautions, that we must approach the study of cerebral localisation." The lesions which are of special value are cases of wounds, laceration, or loss of substance, and various forms of chronic degeneration, such as atrophy, necrosis, etc., and the results of hæmorrhage, inflammation, and the like, which, though at first complex, subside into local lesions, such as softening, cysts, and abscesses; or, in general, all lesions which exclude diffuse meningo-encephalitis, mechanical compression, or general cerebral disturbance.

From the standpoint of regional diagnosis, the exact nature of the lesion is unimportant, except in so far as it is likely to cause irritation or destruction of the cerebral substance. The diagnosis of the nature of the lesion will depend on other characters, such as its mode of onset, general symptoms, and the various recognised features by which we are enabled, with more or less accuracy, to arrive at it. To discuss

these, however, would be foreign to the subject more immediately in hand. I would likewise remark at the outset that, notwithstanding the large and daily increasing body of evidence from the pathological side, for the present at least, physiological experiment is considerably in advance of pathology as regards precision and exactitude; and that, but for the aid of physiological experiment, pathology would not even yet have succeeded in arriving at much beyond general indications as to localisation.

For my part, I should consider it hasty and not to the advantage of "la belle doctrine" of cerebral localisation to make pathological evidence carry more than it can legitimately bear at present, or to found on it measures of treatment, not well considered, the only effect of which will be to make cerebral localisation pray earnestly to be saved from its friends.

*Lesions of the Frontal Lobes.*—I will first direct your attention to lesions of the frontal lobes. The frontal lobe includes the superior, middle, and inferior frontal convolutions, and the ascending frontal or precentral convolution, together with the orbital and internal aspect of the corresponding region (see figs. 1 and 2, with description).

Though anatomically all this region may be included in the frontal

lobe, it is necessary for physiological and pathological purposes to subdivide it, and to term that part which, in its relation to the skull, is roughly bounded by the coronal suture, the *prefrontal lobe* or antero-frontal region (fig. 3). In the monkey, electrical irritation of this region causes no motor reaction; and destruction of these lobes causes no paralysis of motion or sensation. If the positive results, which will be alluded to subsequently, are not altogether definite, the negative results are clear and decided.

There are multitudes of cases on record in which these regions have been the seat of extensive disease on one or both sides with a like negative results as regards sensation or motion; and recovery has taken

\* Pflüger's *Archiv für Physiologie*, Band xlii, Heft i, 1876.

† *Revue Mensuelle*, 1877, No. 1, p. 6.

place after the most frightful lacerations and loss of substance. One of the most remarkable of these is that known as the "American Crowbar Case"; and as this case, in addition to its importance otherwise, has lately been appealed to by Dr. Dupuy,\* as showing that

lesions of the so-called motor region may occur without paralysis, I have thought it necessary to obtain exact particulars in reference to it. And I am enabled, by the kindness of my friend Professor Bowditch of Harvard, to place before you photographic delineations of the skull in

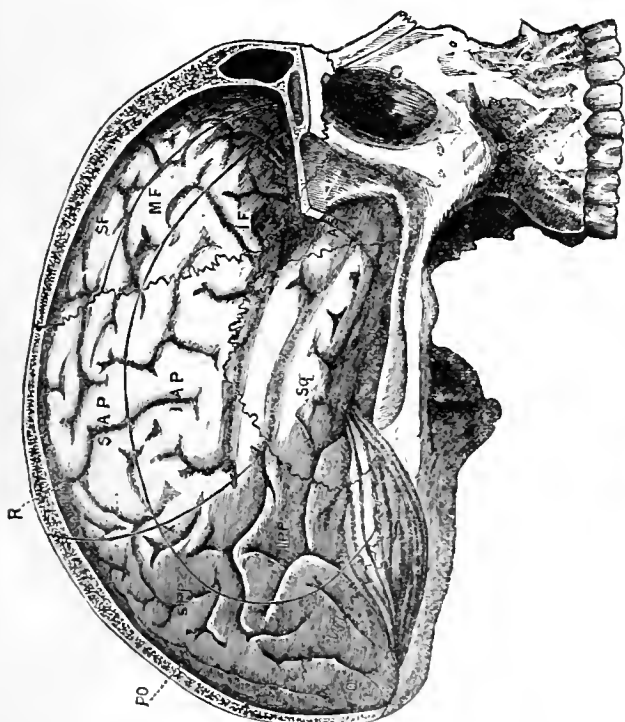

Fig. 3.—Relations of Skull and Brain (Turner).

this case, which was at one time regarded incredulously as a mere "Yankee invention". The skull is preserved in the Medical Museum of Harvard University. There is no doubt about its authenticity. An account of the case was published by Dr. Bigelow,† and another

and later, after the man's death, by Dr. Harlow,\* under whose care he came immediately after the accident, and through whose interest in the man till death we owe the preservation of this unique specimen. (See figs. 4, 5, 6.)

The subject† of the lesion was a young man, Phineas P. Gage, aged twenty-five. While he was engaged tamping a blasting charge in a rock with a pointed iron bar, 3 feet 7 inches in length, 1¼ inches in diameter, and weighing 13¼ lbs., the charge suddenly exploded. The iron bar, propelled with its pointed end first, entered at the left angle of the

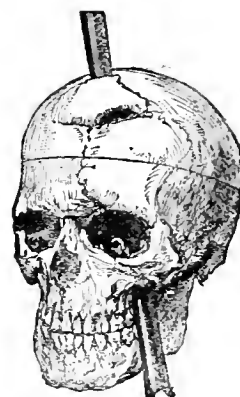

Fig. 5.

patient's jaw, and passed clean through the top of his head, near the sagittal suture in the frontal region, and was picked up at some distance covered with "blood and brains". The patient was for the moment stunned, but, within an hour after the accident, he was able to walk up a long flight of stairs and give the surgeon an intelligible account of the injury he had sustained. His life was naturally for a long time despaired of; but he ultimately recovered, and lived twelve and a half years afterwards. Unfortunately, he died (of epileptic convul-

sions) at a distance from medical supervision, and no *post mortem* examination of the brain was made; but, through the exertions of Dr. Harlow, the skull was exhumed and preserved. Upon this the exact seat of the lesion can be determined. The union of the cicatrices of entrance and exit, however, allowed a pretty accurate estimation of the track of the bar during life, and Dr. Bigelow made experiments on a skull to determine this, and, as the photographs, when compared with figures before you, show,† with very considerable accuracy. Dr. Bigelow, who examined the man two years after the accident, thus describes the appearances presented. "A linear cicatrix of an inch in

† *American Journal for Medical Sciences* for July 1850.

length occupies the left ramus of the jaw near its angle...The eyelid of this side is shut, and the patient unable to open it; the eye considerably more prominent than the other. [Vision lost (Harlow).]...Upon the head, and covered by the hair, is a large unequal depression and elevation...A piece of the cranium of about the size of the palm of the hand, its posterior border lying near the coronal suture, its anterior edge low on the forehead, was raised upon the latter as a hinge, to allow the egress of the bar; still remains raised and prominent."

From his examination of the skull itself, Dr. Harlow thus describes the track of the bar. "The missile entered, as previously stated, immediately anterior and external to the angle of the inferior maxillary bone, proceeding obliquely upwards in the line of its axis, passed under the junction of the superior maxillary and malar bones, comminuting the posterior wall of the antrum, entered the base of the skull at a point the centre of which is an inch and a quarter to the left of the median line, in the junction of the lesser wing of the sphenoid with the orbital process of the frontal bone—comminuting and removing the entire lesser wing with one half of the greater wing of the sphenoid bone—also fracturing and carrying away a large portion of the orbital process of the frontal bone, leaving an opening in the base of the cranium, after the natural effects at repair by the deposit of new bone, of one inch in its lateral, by two inches in its antero-posterior, diameters." (P. 17.) Dr. Harlow does not describe the further track of the bar through the frontal bone, but you will clearly see, from the figures, that the whole lesion is situated anterior to the coronal suture. If, now, you will compare the track of the bar through the skull and brain with the diagram before you (fig. 3), showing the relations between the skull and the brain, you will, I think, have no doubt in convincing yourselves that the whole track is included within that region of the brain which I have described as the prefrontal region, and that, therefore, the absence of paralysis in this case is quite in harmony with the results of experimental physiology. The only other region which the bar could have injured is the tip of the temporo-sphenoidal lobe and the outer root of the olfactory bulb. Respecting the condition as to smell, nothing is, however, said, by either Bigelow or Harlow. This case is generally quoted as one in which the man suffered no damage bodily or mental. But hear what Dr. Harlow says as to his mental condition. "His contractors, who regarded him as the most efficient and capable foreman in their employ previous to his injury, considered the change in his mind so marked that they could not give him his place again. The equilibrium or balance, so to speak, between his intellectual faculties and animal propensities seems to have been destroyed. He is fitful, irreverent, indulging at times in the grossest profanity (which was not previously his custom), manifesting but little deference for his fellows, impatient of restraint or advice when it conflicts with his desires, at times pertinaciously obstinate, yet capricious and vacillating, devising many plans of future operation, which are no sooner arranged than they are abandoned in turn for others appearing more feasible. A child in his intellectual capacity and manifestations, he has the animal passions of a strong man. Previous to his injury, though untrained in the schools, he possessed a well-balanced mind, and was looked upon by those who knew him as a shrewd, smart business man, very energetic and persistent in executing all his plans of operation. In this regard, his mind was radically changed, so decidedly, that his friends and acquaintances said he was 'no longer Gage'." (P. 13.)

After these facts, I do not think it can be said with justice that the man suffered no damage either bodily or mentally, or that the "American Crowbar Case" is in opposition to the experimental facts which I have adduced as to the effect of lesions of the frontal lobes.

A similar case of wound of the frontal lobe, also without motor or sensory paralysis, is related by Bouillaud.\* The wound was caused by a bullet which traversed the upper lip and right nostril, and, passing through the roof of the orbit, emerged at the upper part of the frontal bone, near the sagittal suture.

Trousseau gives a frequently quoted case of an officer who, in a duel, received a bullet, which passed through the head in the middle of the frontal lobes. The man could speak freely, and showed no signs of paralysis of any kind. Death occurred from encephalitis.†

An interesting case of wound of the frontal lobe has been recorded by Congreve Selwyn.‡ A boy aged 4, while at dinner, accidentally fell on a cheese-knife, four inches and a half long in the blade, which penetrated the orbit above the right eye to the depth of three inches and a quarter. After removal of the knife, some brain-matter escaped, and more was discharged on the eighth day. The accident occurred in September 1821. At the date of writing (1838), the only symptoms

observable were blindness of the right eye, dilated pupil, and ptosis. "As regards the present state of his mind, all the senses are perfect, excepting the vision of the injured eye. The memory is very defective. He is incapable of applying to any pursuit requiring mental activity. His disposition is irritable, especially after indulging in liquor, or after any unusual stimulus. He has occasional pain on the injured side of the forehead, and has once had typhus fever since. His bodily health is now good, and he has the free use of the superior and inferior extremities."\*\*

But cases of injury of one or other frontal lobe, without sensory or motor affection, are very numerous. Many are given by M. Pitres, in his recent work,† to which reference may be made for exact citations; a case, by Morgagni, of perforation of the right anterior lobe by a pointed iron; a case, by Morrin, of recovery from a bullet-wound of the left frontal lobe; a case, by Padeau, of recovery after a bayonet-wound of the same region; a case, by Tavignot, of fracture of the frontal bone, and death, without affection of sensation or motion, in which the right anterior lobe was disorganised; a case of wound of the left frontal lobe by the ferrule of an umbrella which penetrated the orbit, related in the *Dublin Journal of Medicine*, 1851; a case of a bullet-wound above one of the orbits, the bullet lodging and causing no symptoms; recorded by Quesnay.

A case has been recently reported by Marot‡ of fracture of the frontal, followed by pyæmia and death, in which it was found that there was effusion into, and laceration of, the first frontal convolution, on the right side. No cerebral symptoms were observed.

The same observer brought another similar case before the Société Anatomique.§ In this, there was depressed fracture of the frontal bone and laceration of the frontal region by a piece of bone. There was no affection of sensation or motion. Death occurred a month afterwards. The laceration occupied the middle frontal convolution of the right side, at the junction of the anterior with the posterior two-thirds. The superior frontal was injured at the same level. There was loss of substance, and an irregular cavity filled with detritus and blood replacing it. There was also slight extravasation over the left frontal lobe. In the discussion which followed, M. Renault quoted a similar case, also without symptoms; and M. Petit two like instances.

I might multiply instances all demonstrating the same fact, that sudden and extensive lacerations may be made in the prefrontal region, and large portions of the brain-substance may be lost, without causing impairment either of sensation or of motion; and, indeed, without very evident disturbance of any kind, bodily or mental, especially if the lesion be unilateral. And if it be true that sudden lesions may be thus latent, *à fortiori*, it might be expected that the slowly progressive lesions of disease would be free from objective symptoms; for it is frequently said that the absence of symptoms may be accounted for by the compensation and functional substitution of other centres: a hypothesis which the negative character of sudden lesions renders altogether inadmissible.

Of cases of softening or abscess, etc., in these regions many are on record. Charcot and Pitres,|| and Pitres in his before mentioned memoir,¶ have collected numerous cases in which one or both frontal lobes have been the seat of disease without any objective symptoms. Time will not permit me to describe these cases in detail, and I will content myself with merely giving the headings: a case of hæmorrhage into the substance of the second right frontal convolution; a case, by Andral, of softening of the orbital lobule of the left hemisphere; a case, by Bergeron, of abscess of the left frontal lobe following a blow; a case, by Hertz, of abscess of the left frontal lobe; a case, by Reed, of fracture of the frontal bone followed by abscess occupying the whole of the right frontal lobe; a case, by Begbie, of abscess of the whole of the left anterior lobe in connection with an abscess of the ethmoid; a case, by Cholmeley, of abscess of the anterior part of the left hemisphere; a case, by Evans, of abscess of the left frontal lobe following a blow; a case, by Prescott Hewett, of abscess of the left anterior lobe; and a similar case by Bouilly. To these, quoted by Charcot and Pitres, may be added a recent case, reported by Lepine,\*\* of abscess of the right frontal lobe, connected with disease of the nasal fossæ.

In all these cases, there was an entire absence of sensory or motor paralysis; and in many, there was nothing recorded or nothing calling for special attention as regards the mental condition. In some of these, however, and in one or two others to be referred to, the psychological

\*\* *Revue Mensuelle*, November 1877, p. 862.

condition seems to have attracted notice. Lepine says of his case of abscess of the right frontal lobe: "He was in a state of hebetude. He seemed to comprehend what was said, but could scarcely be got to utter a word. He would sit down when he was told to do so, and when taken up could walk a few steps with assistance."

A very interesting case is reported by Baraduc,\* in which there was atrophy of the frontal convolutions in both hemispheres. The patient was an inmate of the Hospice de Ménages for six years. His muscular powers and sensation were unimpaired. He was, however, in a state of complete dementia, marching about restlessly the whole day, picking up what came in his way, mute, and quite oblivious of all the wants of nature, and requiring to be tended like a child. The lesion in this case was purely cortical, atrophic, and dependent on partial obliteration of the arterial supply. The lesion occupied the two anterior lobes, that is to say, the first, second, and third frontal convolutions, and also the internal aspect of the frontal lobes. The ascending frontal, ascending parietal, and paracentral convolutions were intact. The rest of the brain was normal, except in the region of the inferior parietal lobule of the right hemisphere (supramarginal and angular gyrus).

Another case, presenting several interesting features, has been put on record by Dr. Davidson.† A labourer received a severe blow on the head with an iron hook, which smashed and carried away a considerable portion of the frontal bone, exposing and injuring the brain as far back as the coronal suture. The injured portion of the brain, as determined *post mortem*, included, on the right side, the greater part of the superior and middle frontal convolutions; and on the left side, a piece of bone was found firmly adherent to the superior frontal convolution at its middle part, this part being disintegrated to the depth of an inch or so. With the exception of a spasmodic extension of the right arm occasionally, the only symptoms of the cerebral lesion in this case were of a psychical nature. Though the man seemed to understand what was said to him and did what he was told, "every action he performed left the impression on the mind of the observer that it was purely automatic" or machine-like.

Marked mental deficiency has been frequently noted in connection with arrested development, or atrophy, of the frontal lobes, without any objective symptoms as regards motility or sensibility. One good instance of this has been described and figured by Cruveilhier. This was a case of a girl aged 15, who had remained in a complete state of idiocy from birth. The prefrontal regions or anterior two-thirds of the frontal lobes in this case were completely wanting. But, indeed, the frequent association of idiocy with such defect of the frontal lobes is a generally recognised fact.

Whatever opinion we may form as to the positive indications of disease of the prefrontal lobes, I think it is abundantly manifest, from the cases I have cited from among many, that, in the total absence of affections of motility or sensibility, whether in connection with sudden or slowly progressive lesions of these regions, we cannot attach objective motor or sensory functions to them. With such evidence before us, to say nothing of the facts of experimental physiology, we cannot regard cases in which, with lesions in the prefrontal lobes, sensation or motion has been affected, as other than cases of co-existence or multiple lesions, whether organic or functional. Between lesions of the prefrontal lobes and such symptoms, we have no grounds for assuming even indirect causal relationship, unless they can be shown to be of very frequent, if not constant, occurrence. Such relationship we all admit in the case of tumours, which, as we know, influence regions at a distance from the actual seat of disease; or in the case of diseases spreading backwards, such as encephalitis or meningitis.

It is chiefly on the indirect or accessory symptoms that we at present rely for our diagnosis of lesions in the frontal regions. We may obtain indications from the history of some traumatic lesion, or from the proximity of some such affection as disease of the nasal fossæ; or we may have uncertain signs of pain localised in the frontal region; or there may be disturbances of the sense of smell. But, in the absence of all these—and they may be absent—the question is: whether there are any symptoms directly indicating disease of the prefrontal lobes? Even if we have to admit that such symptoms cannot be definitely specified, yet it will not have been in vain if experimental physiology has succeeded in bringing into prominence certain facts to which attention should be more particularly paid in future.

Touching the effects of removal of the prefrontal lobes in monkeys, I may be allowed to quote from myself: "Removal or destruction by the cautery of the antero-frontal lobes is not followed by any definite physiological results. The animals retain their appetites and instincts, and are capable of exhibiting emotional feeling. The sensory faculties,

sight, hearing, touch, taste, and smell, remain unimpaired. The powers of voluntary motion are retained in their integrity, and there is little to indicate the presence of such an extensive lesion, or a removal of so large a part of the brain. And yet, notwithstanding this apparent absence of physiological symptoms, I could perceive a very decided alteration in the animals' character and behaviour, though it is difficult to state in precise terms the nature of the change. The animals operated on were selected on account of their intelligent character. After the operation, though they might seem to one who had not compared their present with their past fairly up to the average of monkey intelligence, they had undergone a considerable psychological alteration. Instead of, as before, being actively interested in their surroundings, and curiously prying into all that came within the field of their observation, they remained apathetic or dull, or dozed off to sleep, responding only to the sensations or impressions of the moment, or varying their listlessness with restless and purposeless wanderings to and fro. While not actually deprived of intelligence, they had lost, to all appearance, the faculty of attentive and intelligent observation."

I have elsewhere attempted some explanation of the faculty of attention—the basis of the higher intellectual operations—and its relation to the anatomical substrata of the prefrontal lobes; but I will not enter further on these speculations at present. I would, however, call your attention to the psychical characters in some of the cases of disease and injury of the frontal lobes to which I have referred (*e.g.*, the American "Crowbar" case, Baraduc's, Selwyn's, Lepine's, Davidson's), as, in many respects, similar to those seen in monkeys after removal of the prefrontal lobes. I may also adduce the observation of Dr. Crichton Browne on General Paralysis of the Insane,‡ tending to show that the earlier symptoms, *inter alia* "general restlessness and unsteadiness of mind, with impairment of attention, alternating with apathy and drowsiness" (page 223), coincide with the morbid changes occurring at this stage, more particularly in the frontal regions.

## ON SOME POINTS IN THE CLINICAL HISTORY OF CHOREA.‡

By W. R. GOWERS, M.D.,

Assistant-Professor of Clinical Medicine at University College.

THE object of the following paper is to call attention to, and illustrate by cases, some points in the common or occasional clinical history of Chorea, which have hitherto received little notice. The points specially considered are four: the electrical condition of nerve and muscle in chorea; the proportion between the choreiform movements in their relation to the will; the distribution of hemichorea; and the relation, occasionally to be observed, between chorea and certain convulsive disorders. The patients whose cases are narrated, except when it is stated otherwise, were under my care at the National Hospital for the Paralysed and Epileptic.

### I.—THE IRRITABILITY OF NERVE AND MUSCLE IN CHOREA.

Observation on this point can only be made, with accuracy, on patients with hemichorea, in whom the irritability of the unaffected side can be taken as a standard for comparison. An examination of such cases shows that, a few weeks after the onset of the affection, there is to be observed, in most, though not in all, cases, a distinct increase in the irritability of both nerve and muscle on the affected side, the increase existing to both faradisation and to the voltaic current. The difference varied in the cases examined, from one to three *centimètres* of the secondary coil of Stöhrer's larger induction apparatus, and from two to five cells of the Stöhrer or Leclanché voltaic battery. The change was always in the same direction to both faradisation and the voltaic current. The increase in irritability was found to subside with the subsidence of the chorea. The following cases illustrate the alteration.

CASE 1. *Hemichorea: Increased Irritability of the Muscles of the affected Arm.*—A healthy-looking lad, aged 14, noticed slight unsteadiness of the right arm the day after some severe rowing, he having had an attack of severe general chorea two years previously. A fortnight after the onset of this second attack, there were slight occasional choreic movements of the right arm, varied by an occasional sudden start, and there was also slight inco-ordination on movement. There was no cardiac murmur. The electrical irritability of the muscles of the two arms was carefully compared, and was found to be greater in the right

\* *Functions of the Brain*, p. 230.

† *West Riding Reports*, vol. vi, p. 170.

‡ Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877.

\* Soc. Anat., March 1876; *Le Progrès Méd.*, Aug. 19th, 1876, p. 598.

† *Lancet*, March 10th, 1877, p. 342.

(affected) arm than in the other. A similar difference was observed to both faradisation and the voltaic current. The irritability was equal in the biceps, the difference being in the forearm and hand muscles. On the right side, for instance, the extensor communis digitorum contracted to ten cells of a Stöhrer's battery, while on the left side fourteen cells were required to produce the slightest contraction. A month later, the same difference was still present; the common extensor contracted to one centimetre less of the secondary coil of Stöhrer's larger induction apparatus, and to six cells less of the voltaic battery.

**CASE II. Right Hemichorea: Increased Irritability of Muscles of the Right Arm, subsiding with the Chorea: Subsequently Left-sided Chorea, with Increased Irritability in Muscles and Nerves of the Left Arm.**—A child nine years of age had, when seen, suffered from unilateral chorea for two months; the movements being first noticed a fortnight after a fall out of a window. There were slight choreic movements and inco-ordination, in the right arm only. On testing the muscles, it was found that the irritability to faradisation, in both flexors and extensors of the forearm, was distinctly greater on the affected side. Three weeks later, the movements had almost ceased, and, a fortnight later, had quite ceased; and on again testing the muscles, no difference could be found between them of the two sides: the increased irritability had subsided. Two months later, the child reappeared with slight left-sided chorea of a week's duration. Very distinct choreic movements were present in the left arm. No distinct alteration could be discovered in the electrical irritability of the muscles or of the nerves, even as high as the brachial plexus. A fortnight later, the child was again examined. The chorea was still well marked on the left side, and absent or almost absent on the right. Both muscles and nerves of the left arm now presented a very distinct increase in their irritability. The flexor communis digitorum contracted to three centimetres less of the secondary induction coil, and to four cells of the voltaic battery less than the right. The left extensor communis digitorum contracted to the same strength of the induced current, but to two cells less of the voltaic battery, than the right. The same increased irritability was found in the median nerve, the left acting to two centimetres less of the secondary coil and four cells of the voltaic battery less than the right.

**CASE III. Hemichorea: Increased Irritability in Muscle and Nerve on the affected Side, subsiding with the Chorea.**—A man, aged 25, came under treatment with characteristic choreic movements, limited to the left arm, spontaneous, and interfering with voluntary movements. In all the muscles compared (flexor and extensor of wrist, and abductor indicis) the irritability was greater on the affected than on the healthy side; about two centimetres less of the secondary coil of Stöhrer's apparatus being required. The left ulnar nerve was one centimetre more irritable than the other. The muscles presented the same difference in their irritability to the voltaic current as to the faradic; and in the nerves the difference to voltaism was still greater, the right responding to twelve cells and the left to eight cells. Three weeks later, the arm was almost well. Electrical examination then showed a slight excess in the irritability of the muscles of the affected side, although the difference was less than before. It could not be noticed in the extensor of the forearm, but was distinct in the flexors and in the ulnar nerve. A month later, all spontaneous movement had disappeared, and with it all increase in irritability. The ulnar nerve, indeed, seemed a little less irritable than on the unaffected side.

In another case, described below (Case v), in illustration of another important point, the same increase was observed.

The existence of this change in the irritability of the muscles in hemichorea, in which the movements were characteristic, justifies the inference that it exists in cases of general chorea. The observation is not a new one. It has been made by Rosenthal and Benedikt; but I am not aware that their statements have been previously confirmed in this country. The same observers have asserted that a marked deviation from Pilüger's law is to be observed in chorea, a greatly increased sensitiveness to the cathodal opening contraction being observed. I have not been able to detect so profound a deviation from the usual order; but I have observed the anodal opening contraction occur, not only earlier than the anodal closure, but so much earlier than normal that it occurred almost as soon as the cathodal closure contraction.

What is the significance of the increased irritability in nerve and muscle which may be assumed to exist in many, probably in most, cases of chorea, which have lasted for a certain time? I do not think that it can be regarded as a local change, consequent on the overaction of the nerves and muscles of the affected limb; for the overaction in some of the cases was far too slight to account for such an effect. The increase in irritability is to be regarded as the expression of a change in the nutrition of the nerve-fibre; and we have learned to regard the nutrition of the nerve-fibres as depending on the grey matter of the cord, probably on the nerve-cells of the anterior cornua, with which

they are connected, and of which they are in effect the processes. Indeed, it is probably not too much to assert that, in testing the irritability of the motor-nerves, the nutrition of which is unaffected by any local cause, we are really testing the state of nutrition of the motor nerve-cells of the spinal cord. The increased irritability is, therefore, the indication of a change in the nutrition of those nerve-cells, similar to that which is expressed by the granular and other changes lately found by Mr. Sankey and myself in these cells in the chorea of the dog.\* The change in their nutrition is no doubt the result of an irritation propagated down the cord upon them from the changed encephalic centre, and is similar to that which occurs in some cases of hemiplegia, from an irritative lesion in the corpus striatum; and it is an instance, if slight yet distinct, of the way in which "functional" disturbance is attended with nutritive change.

## II.—ON THE RELATION OF THE MUSCULAR DISTURBANCE IN CHOREA TO VOLUNTARY MOVEMENTS.

Two elements may be, and commonly are, distinguished in the choreic disorder of movement: first, the spontaneous movements; and secondly, what may be termed the inco-ordination of voluntary movement. The latter term is a convenient one, but its accuracy may be questioned; since it may be urged that the so called inco-ordination is simply the result of the inability of the will to quell the spontaneous spasm during voluntary movement. I believe, however, that an inco-ordination may often be recognised over and above the spontaneous spasm. But a distinction of the two elements is sufficient for the statement of the point to which I wish to call attention, which is that this inco-ordination of voluntary movement and the spontaneous spasm, although frequently proportioned, bear no necessary relation to one another, either when compared in different cases or even in different periods of the same case. In illustration, I may cite the following cases.

**CASE IV. Chorea of One Month's Duration: Spontaneous Movements slight: Inco-ordination great.**—A boy aged 6 had suffered from chorea for a month, when he came under observation. The attack began gradually without assignable cause. The affection of the two sides was equal, and consisted in very slight spontaneous movements of arms, head, and legs—so slight as almost to escape notice. On trying to execute any movement, the inco-ordination was extreme. If he tried to grasp an object, the fingers were twisted about and the hand thrown about in a wild manner. There was no cardiac murmur.

**CASE V. Repeated attacks of Chorea, following Acute Rheumatism: Much Spontaneous Movement; Little or no Inco-ordination; Increased Irritability in Muscles.**—M. W., a girl aged 18, in October 1875, came under treatment for her fourth attack of chorea. At 14, she had had an attack of acute rheumatism, in which her heart was affected. At 15, she had a severe attack of chorea, which commenced a fortnight after a fright (being knocked down by a horse). She had a second attack at 17; a third attack at 17½, which commenced the day after a severe fright at a thunderstorm. The fourth commenced a week after she had been startled by an unseen person. In every attack, the affection was general, but the left side was the more severely affected. In the last, the spontaneous spasm was constant and great, but there was very little inco-ordination of movement; she could hold an object placed in her hand quite steadily. She had a loud mitral systolic murmur. This patient came under treatment again a year later with a fifth attack, limited to the left arm. In this the spontaneous movements were distinct, though not extensive; but there was no inco-ordination of voluntary movements. In all the muscles of the affected arm, the irritability was increased to both faradisation and the voltaic current, the increase of the former amounting to two centimetres of the secondary coil.

**CASE VI. Second Attack of Chorea: much Spontaneous Spasm: no Inco-ordination.**—Lydia B., aged 18. Second attack of chorea. She had never suffered from rheumatic fever, but her father had died from it. The first attack had commenced two years previously without assignable cause, lasted six months, and affected the right side only. The second attack commenced three months before she came under treatment; for three weeks the right hand only was affected, then the left also became affected, and for several weeks the left side was worse. At the commencement of the attack, speech was much interfered with. At first, the chorea was worse in the morning and better in the evening. When seen, the mind was unaffected, face free from movement, the arms were the seat of considerable chorea; twitching and fidgety movements constant. There was, however, scarcely any inco-ordination of voluntary movement. She could pick up an object, as a pen, without any difficulty, and hold it out at arm's length for a quarter of a

\* *Medico-Chirurgical Transactions.*

minute with perfect steadiness. The legs were free from movement. There was no cardiac murmur.

**CASE VII. Chorea: Three Attacks: much Spontaneous Movement, but no Inco-ordination.**—Mary Y., aged 12, a healthy-looking child, had a first attack of chorea when nine years of age, which commenced three days after a fright. The attack lasted only a few weeks. A loud systolic apex murmur was present. She had never had rheumatic fever. A second attack of chorea occurred nine months later, and also lasted a few weeks. She continued free from the affection for two years, and then came again under observation with a third attack. In this there was much spontaneous fidgetty spasm in both hands, but hardly a trace of inco-ordination. She could pick up a small object from the table quite steadily. The mitral murmur continued loud: heard both at the apex and at the angle of the scapula.

**CASE VIII. Variation in proportion of Spasm and Inco-ordination at different periods of Attack.**—A little girl aged 12, when first seen at University College Hospital, had slight chorea, of a week's duration, and confined to the left arm. There were very slight spontaneous movements, characteristic in form. There was great inco-ordination, out of all proportion to the spasm, so that it was with difficulty that she could pick up an object. The grasp of the left hand was distinctly weaker than that of the right. A week later, there was much more clonic (choreic) spasm, marked in both foot and hand. The inco-ordination, however, was much slighter; she could pick a very small piece of paper from the table without any difficulty. There was no murmur at the apex or base of the heart, but just within the apex was a long systolic murmur: heard in a very limited area, not conducted. A month later, she was nearly well, and the murmur could only be heard with an occasional beat of the heart.

These cases prove, I think, the assertion that, in chorea, inco-ordination of voluntary movement bears no relation to the spontaneous spasm, but varies independently. It is clear that this variation must depend on one of two causes; either the power of the will to overcome the spontaneous spasm is subject to variations altogether irrespective of the degree of that spasm; or else there is, as I believe, an inco-ordination to be recognised which varies independently of the spontaneous movements. I believe that it will be found that, when such a disproportion exists, the inco-ordination is in excess of the spontaneous spasm early in an attack, and the spontaneous spasm is in excess of the inco-ordination late in an attack and during relapses.

The independent variation in these two elements in chorea suggest that they may depend on an affection of distinct and separate regions of the nerve-centres. It is not easy to conceive that so considerable a variation as was noted in some of the above cases, can be due to a variation in the affection of one region.

[To be continued.]

## ON THE GENERAL UTILITY OF SPONGES AS SURGICAL DRESSINGS, AND ON TEREBENE AS A SURGICAL AGENT.

By FURNEAUX JORDAN, F.R.C.S.,

Surgeon to the Queen's Hospital; Professor of Surgery at Queen's College; Consulting Surgeon to the Women's and the West Bromwich Hospitals.

I FULLY recognise the value of the antiseptic treatment as taught by Mr. Lister. A method of treatment which enables us to open important cavities and make deep incisions, for diagnostic and other purposes, without danger, constitutes an epoch in surgery as great as the introduction of lithotomy, amputation, or anaesthesia.

Sometimes, however, unavoidable circumstances prevent our using antiseptic precautions. The operating surgeon is frequently called upon to perform even important operations with but little assistance. He may be called upon, especially in country districts, to remove (say) the breast with only three pairs of hands in the room, one pair being confined to the management of anaesthesia.

There are certain localities also, as the face and the mucous outlets and their vicinity, where functional exigencies prevent the adoption of a treatment which, although of inestimable value, involves much detail, complicated apparatus, the isolation of large surfaces, and long periods of non-interference.

For the last few years, I have used sponges as dressings after many operations and injuries. At one time, there was a great dread of sponges, even for operative purposes—a dread which was tersely expressed thus: "Whenever and wherever you see a sponge, throw it into the fire." The introduction of more efficient antiseptic fluids has

changed all this. In reality a sponge conveys, renews, or maintains antisepticity with signal convenience and efficiency. A soft, cleansed, moist antiseptic and sufficiently large sponge may be put over, or occasionally even within, the parts which have been recently injured or operated upon with benefits so marked as to deserve printed commendation. Such a dressing apparently secures all the conditions which favour the healing process; and all that we can do is to control conditions. We have no surgical charms, royal touch, or prayers which are able to heal.

A sponge exerts a soft, uniform, diffused, elastic, and measurable pressure. Slight pressure will keep a wound clean; moderate pressure keeps up efficient drainage of all deep-seated fluids, and renders the ordinary drainage-tube, as a rule, unnecessary. The drainage (and pressure) of a sponge is diffused and complete; the drainage of a tube is local and incomplete. In many cases, where I have used a tube with a superjacent sponge, I have found, on removing the first sponge after some days, all the parts healed, except the locality of the tube. In similar cases, where the tube has not been used, the healing has been complete. There is one structure which, in my experience, strongly resents the presence of an India-rubber tube passed through its substance: it is the female breast, multiple abscesses arising in the vicinity of its tract.

Moderate sponge-pressure also keeps the deep parts in apposition, and thus promotes the deeper solid union—a greater virtue no dressing can possess. A little more, though not at all severe, pressure arrests hæmorrhage from all except the larger vessels; even the latter might, if necessary, be held in check for a considerable time. In operations and injuries, where hæmorrhage is free and from many and not large vessels, as in wounds of the palm, indeed in any operation or injury involving the hands and feet, the advantages of a sponge and bandage are clearly seen. In operations on the breast, especially where axillary glands require removal, I look on a big sponge as my best friend. In some cases such as these, a bit of sponge put inside the wound (Mr. Lister's writings first suggested this to me), the margins being drawn together, or a large sponge placed thereon, instantly stops all bleeding. Here I should change the first dressing, as soon as the probability of primary and reactionary hæmorrhage had passed away, so that deep union might not be hindered. There is probably some physical peculiarity in sponge which tends to arrest hæmorrhage, independently of mere pressure. Protracted pressure with lint or cotton, sufficient to arrest hæmorrhage, would cause sloughing; it is not so with sponge-pressure. Sponge "hites" the skin, and thus keeps the superficial parts in place, while its elastic pressure keeps the deep parts together. I will now merely hint at some other of its qualities. Sponge may be kept very wet or slightly damp, hot or cold, small or large, by merely altering the character and the amount of the fluids which may be applied to it; all this is possible without removing the sponge. The lotion may be nearly boiling, or it may be constantly iced. Fluid may be applied with any frequency; it may be medicated with any approved agent. Lotions which give deposits, as those containing lead, are not so suitable, as they harden the sponge—a condition which can rarely, if ever, be necessary. If the sponge-dressing require to be prolonged more than a few days, the lotion must not be of a character or a strength to unduly irritate the skin.

Turkey sponge is better for smaller wounds and operations; in larger lesions, the honeycomb is more manageable. Sponge-dressings may be removed frequently, or, which is much more important, very infrequently. The softness and bulk of damp sponge protect from movement, friction, blows, or other injury. Sponges take any shape, may be adapted to any surface, or cut to any size. Two or more (stitched together or not) may be used when one is not large enough or only small ones are available.

It is well to have separate suitably shaped and prepared sponges for dressing; but, if this be overlooked or be inconvenient, the operation-sponges may be used. Sponges which have been used, if completely cleaned and disinfected, are even better than new ones.

How long should we continue the sponge-dressing? Not long; until all danger of urinary and recurrent bleeding has ceased; until deep union is fairly established and there is little fear of the separation of parts; until (which is much the same thing) the discharges have become slight and the wound is mainly superficial. All these results I very frequently find on removing the first dressing, which has remained some days—three, four, six, eight, or ten.

In amputations of the limbs, sponges, one or two, may be readily made to cover the incisions, support the deep parts, check hæmorrhage, drain, and act as splints. In removal of the breast and tumours generally, the sponge-dressing has special advantages. The sponge should be large; say, in a woman of medium size, ten or eleven inches long, five or six wide, and four or five thick. It should be placed

directly over the stitches or strapping; indeed, it is one of the merits of the sponge that it can be placed over any other contrivance. If strips of plaster be needed to relieve tension, they should be long—say from over the shoulder to near the groin—when the slight moisture of the sponge will not spoil their adhesion. A few neat and firm turns of wide, thin, smooth bandage are better than a large number in several ways, especially in the medication or antiseptication (may I say?) of the sponge. During the few years I have used sponge-dressing, I have not had a single instance of early recurrent or later reactionary, or of secondary hæmorrhage. I scarcely ever tie a vessel. One or two may be twisted or compressed a few minutes by spring-forceps; but patient pressure for a time with relays of well-wrung sponges within the wound rarely fails to stop primary hæmorrhage.

In the deep excision of cancers from mucous outlets—a branch of surgery in which it falls to my lot to have much experience—I should be much at a loss if I had not at hand my large sponge with its antiseptic, styptic, compressing, and draining properties. A few months ago, I removed a cancerous penis as far down as the triangular ligament in the perinæum (splitting the scrotum to do so, the man preferring to retain the testes); a sponge with a catheter passed through its centre, stopped the bleeding, dressed the wound, and kept it antiseptic, all at once.

I need not detail every operation in which sponge-dressing is of benefit; I will briefly refer to a few only. I have just had striking evidence of its utility in trephining. Twenty-one days ago, a young man was brought into the Queen's Hospital with a cut, and therefore a comminuted and depressed, fracture of the right parietal bone, caused by a falling slate. Brain was oozing out, and as much as would fill a walnut-shell escaped. Left hemiplegia was marked, but not complete. I trephined, and removed numerous fragments and a bit of felt hat, leaving a gap two inches long and an inch and a half wide. The soft parts were very loosely adjusted, and well covered and overlapped by a soft sponge kept constantly moist with terebene, and fixed by one strip of adhesive plaster twenty inches long and three inches wide. On this, the fourteenth day, his state could not be more favourable.

In wounds generally, in compound fractures, after operations for caries or necrosis, after opening abscesses, superficial or deep, the sponge-dressing is of ready utility.

After operations for hernia, a large antiseptic sponge under a few turns of spica bandage forms an ideal dressing, which at once gives elastic-truss pressure, cleanliness, drainage, and antisepticity.

After lithotomy, when there is free bleeding, there is no mechanism which equals in accessibility, simplicity, and efficiency an elongated bit of sponge, a kind of sponge-tent, passed by the side of an elastic tube or catheter. I have now in the hospital a man, aged 75, who is convalescent from lithotomy. The stone was very large, the incision necessarily free, the hæmorrhage great, and the patient naturally feeble; after a few spoonfuls of iced water, I put a large elastic catheter through the wound, and by its side a sponge-tent of the size of my finger. In a few moments, the bleeding ceased, not to return, the urine shortly came through the catheter. All went on well, save that severe signs of senile exhaustion appeared after seven or eight days; these were successfully checked by repeated alteration in position, and even partially clothing the patient: the risk of a permanent fistula, from getting up too soon, seemed better than death. In lithotomy wounds, as elsewhere when the sponge is put within the wound, it speedily creeps into every corner, crevice, or recess from which blood may flow. It is on this principle that an ordinary uterine sponge-tent, passed along the floor of the nose, as recorded by a surgeon whose name I forget, checks epistaxis immediately, without time, trouble, or apparatus.

In the later stages of injuries and operations, and in surface lesions generally, I find terebene a most useful dressing, pure or mixed with water. It is an excellent addition to the sponge-dressing, which it readily keeps moist and soft. Occasionally, however, if used with firm pressure and under many layers of bandage, it causes a little pimply redness of the skin; this is of slight importance, as it never leads to erysipelas or deeper inflammation. The remarkable experience of Mr. Waddy of Gloucester, who used only one dressing in operations, with frequent additions of pure terebene, deserves more attention than has been given to it.

Terebene, which was introduced by a well-known officer of health, Dr. F. T. Bond, is not poisonous internally; it is astringent and hæmostatic, but not escharotic. It is a powerful disinfectant; as a deodorant, it is without an equal: it is something more than a deodorant, it diffuses an agreeable and soothing odour. It may be used without diluting, mixing, shaking, stirring, or other preparation, or it may be mixed with water, and very readily with olive oil. With a third or half of olive oil, it forms a surface-dressing of very general utility. Lint and tow absorb it readily. For burns, ulcerations, sloughing conditions, the

various gangrenes and open cancers, terebene does all that a dressing can do, and entirely removes all ill odour from the parts from the room. Terebene is a very suitable dressing for cavities that require to be temporarily stuffed, as after the removal of carious or necrosed bone. Its non-poisonous character and its fragrance especially adapt it as a dressing after partial or complete removal of the upper jaw.

To return for a moment to the subject of sponge-dressings. Now and then, under exceptional circumstances, it is probable that surgeons have left a sponge in a surgical dressing. Since the above notes were put together, I have seen the surgical application of sponges recommended in an American serial. Quite recently, an able surgeon, Mr. Chiene, has advocated sponges as a cheapening adjunct to the antiseptic method. I simply desire to point out the advantages of a general and systematic use of constantly moist antiseptic sponges in checking and preventing hæmorrhage, in adjusting, uniting, cleaning, draining, antiseptising, and protecting wounds.

## ON EFFUSION INTO THE PERITONEAL CAVITY ANALOGOUS TO LATENT PLEURISY.\*

By JOHN SMITH, M.D.,

Physician to the Dumfries and Galloway Royal Infirmary.

IN the BRITISH MEDICAL JOURNAL of September 16th, 1876, Dr. George Johnson published four cases of serous effusion into the cavity of the peritoneum, which he characterised as a class of the affection which, so far as he was aware, had not been recorded by writers on the practice of physic. He also considered that they bore by their peculiarity an analogy to cases of so-called latent pleurisy, in which we find a copious pleuritic effusion without a previous history of, and unaccompanied by, pain or febrile disorder. I have to record two cases which have come under my treatment, and which appear to bear the same analogy as those referred to by Dr. Johnson.

CASE I.—Jane M., aged 22, was admitted to the Dumfries and Galloway Royal Infirmary on May 15th, 1875. She was unmarried, and had always been healthy until about three months before, when she contracted typhoid fever, which lasted about four weeks. Three weeks or so after rising from the fever, and about a week after she had menstruated, she observed swelling in the lower part of the belly, which increased rapidly. She had no pain or uneasiness, and pressure or handling did not cause her any annoyance. On examination, the patient lying on her back, the abdomen was found much enlarged, having a broad flattened appearance, and bulging considerably and equally in both flanks. Percussion elicited resonance in the anterior and upper part, and dulness in the sides. Change of position altered the percussion-sound, being dull at the most dependent part and resonant at the upper. Palpation could detect no solid tumour, and the fluid wave was quite easily seen and felt. The heart, lungs, kidneys, and liver were, so far as could be ascertained, healthy and acting normally. There was no increase of temperature, and the pulse was natural.

After consultation with my colleagues, this was considered a case of ascites, and she was ordered hydragogue cathartics and diuretics. After giving these a fair trial without apparent benefit, she was ordered syrup of the iodide of iron and full diet, and to have gentle exercise. A short time afterwards, she commenced to improve; and, about four weeks after the supportive treatment began, she left the house much better in health, with the abdomen much reduced in size, but still containing a considerable amount of effused fluid. Several months after she left the Infirmary, her medical attendant wrote concerning her, that the abdominal enlargement had entirely disappeared.

CASE II.—Jane A., aged 28, consulted me in July 1875 for a swelling of the abdomen, which she had observed about three weeks previous to my seeing her. She had several times within the last twelve months observed a similar swelling immediately after her menstrual period; but it never became so extensive, and always went away. She had always been otherwise healthy, and menstruated regularly. From the commencement of the swelling until recently, she had not experienced the slightest amount of pain or uneasiness. Two or three days previously, however, she began to have a distensive feeling, which had gradually increased to severe pain; and her breathing had been rather difficult. The abdomen was much distended, of a rounded symmetrical form, resonant on percussion at the anterior and upper part, and quite dull at the lower and lateral. On altering the position of the patient, the bulging and dulness changed to the most dependent part; and the level of the fluid could be distinctly made out in whatever position she

\* Read at the Autumnal Meeting of the Border Counties Branch.

was placed. The fluctuation-wave was easily felt. The heart and lungs were healthy; and the liver, so far as could be ascertained, was natural in size and action. There was no trace of jaundice; the urine was natural in appearance and free from albumen; the pulse was 102, and the temperature normal. Owing to the severity of the symptoms, I suggested tapping as the surest and most expeditious way of giving relief; but, this being objected to, I ordered forty grains of the compound jalap powder to be given. On visiting my patient on the following morning, I found her somewhat relieved; the bowels had acted very freely, and the urine was more abundant. I then ordered the following diuretic.

R Potassæ acetatis ʒii; spiritus ætheris nitrosi ʒvi; syrupi scillæ ʒi; decocti scoparii q. s. ad ʒvi. A teaspoonful in cream of tartar water to be given every six hours.

Under this treatment, she gradually improved; the pain ceased, and the abdominal enlargement speedily lessened. After continuing the diuretic for about a fortnight, I substituted for it ten grains of the carbonate of iron (saccharated), to be taken three times daily after meals, and ten-minim doses of the tincture of digitalis thrice daily, an hour before meals. The patient was also ordered good nourishment, and to have gentle open-air exercise. Within three months from the commencement of my treatment, no ascites could be detected; and, although she has frequently since consulted me for dyspepsia and general debility, no effusion into the peritoneum has returned.

The accumulation of serum in the peritoneal cavity is generally understood to depend on one of two causes—first, and most commonly, on some obstruction to the return of blood from the peritoneal blood-vessels; and second, on some modification of the action of these blood-vessels, and probably of the lymphatics contained in the peritoneal membrane. That the cases which Dr. Johnson has published, and those that I have here recorded, approach in their nature to the second class, cannot be doubted; but the almost total want of evidence of inflammatory or tubercular action characterises them as a very rare or previously unrecognised affection. Several cases of latent pleurisy have come under my notice—cases in which the first symptom of the disease was the discomfort occasioned by the presence of effused fluid, and into which the most searching inquiry from the patient could elicit nothing betokening pleuritic pain or other symptoms of pleurisy. From what I have observed in these cases and the analogous cases of peritoneal effusion, I am led to think that the accumulation is rather due to a peculiar state of the constitution, whereby the power of absorption is abridged, while the progress of exhalation is unchecked, than to any local cause. Dr. Johnson has applied to the cases he has recorded the term subinflammatory effusions, attributing them to a subinflammatory process of a local nature. As a type of what may be termed subinflammatory effusions, we may instance the common complaint of hydrocele, which is purely a local affection, the result of some change in the tunica vaginalis testis, whereby the proper balance of power between absorption and secretion is lost. In such cases, no constitutional treatment will restore to that membrane its normal equilibrium of action; and nothing short of local interference will suffice to effect a cure, which fact goes far to prove their local origin. In the two instances I have specified, from the history of the cases, both occurring at a time when the constitution was enfeebled, the one after fever and the other after menstruation, and from the beneficial results of constitutional treatment, I am led to the conclusion that their origin was more from the loss of constitutional than of local power. I am persuaded that, as in cases of hydrocele no constitutional treatment would have the necessary topical effect, so in cases similar to those I have here described no local interference would be effectual in setting up and maintaining normal action.

Believing with Dr. Johnson that it is highly important, for correct diagnosis and successful treatment, that such cases should be distinguished, I have placed my experience before the profession, with the hope that by so doing others may be enabled to recognise and successfully treat similar cases.

## SURGICAL MEMORANDA.

### ANTISEPTIC SURGERY.

DR. THOMAS'S contribution to the statistics of antiseptic surgery is welcome; but I must decline to allow him to manipulate my table so as best to suit his special pleading. My statistics consisted of fifty-five amputations and excisions, not of thirty-five amputations only. It is true I included four amputations of the forearm, inclusive of one at the elbow-joint, to which Dr. Thomas takes exception; but, as the latter proved fatal, I thought it best to include it. The table also contained a

case of removal of a loose cartilage from the knee-joint, and an operation for ununited fracture of the forearm, because such operations are prone to some of the evils resulting from septicity; and I must, therefore, request to be allowed to reconstruct my table as consisting of fifty-five operations, with five deaths, showing a mortality of 9.09 per cent., and not, as given by Dr. Thomas, of thirty-five amputations, with four deaths, showing a mortality of 11.42. It is manifest, however, that Dr. Thomas extracts the amputations alone in order to compare them with the more favourable results obtained by one of the surgeons in the Glasgow Infirmary styled "F.", during the same period, who had thirty amputations, with one death, giving a mortality of 3.22 per cent.

Having made his selection and added his contribution from the Glasgow Infirmary, Dr. Thomas proceeds to remark: "A glance at these tables will show the great superiority, so far as results are concerned, of Mr. Lister's method over Mr. Bradley's."

Similarly, I will take the liberty of remarking that, if Dr. Thomas will turn to the *St. Bartholomæw's Hospital Reports* for 1874, he will find sixteen consecutive amputations tabulated by Mr. Callender, without a single death, and, the following year, forty-four consecutive amputations, with but one death, which should equally clearly convince him of the great superiority of Callender's method over Lister's; a conviction which must be distressing to Dr. Thomas, since, by parity of reasoning, he must admit that this superiority is due to open dressing and avoidance of Listerism.

I did not, however, furnish my statistics with the intention of proving that I had the smallest percentage of deaths, but for the purpose of seeing how far the deaths were due to septic, and therefore removable, causes. I found that the five deaths were respectively due to typhoid fever, hæmorrhage, diathetic causes, shock, and mental depression; and, unless Dr. Thomas is prepared to maintain that Listerism is protective against such ills as these, I cannot admit that an honest examination of the two tables "shows the great superiority of Mr. Lister's method" over my own.

This part of my argument, which is the very gist of the whole matter, Dr. Thomas completely ignores, and goes on with his comparison as though nothing of the kind had been said.

S. MESSENGER BRADLEY, Manchester.

### CATGUT LIGATURE.

IN the JOURNAL for March 23rd, Mr. Messenger Bradley refers to a case in which he tied the hind (third?) part of the right subclavian artery with a catgut ligature, and, from the issue of this case, he arrives at conclusions respecting the safety of that material which, I think, ought not to pass without some comment.

"The patient", he says, "died of cardiac disease on the eighth day following, and, on examination, it was found that the ligature had, with the exception of a short interval about one line in length, completely cut its way through all the coats of the vessel. There was no occlusion whatever of the artery, nor even any coagulum, so that doubtless the hæmorrhage would have been very fierce and uncontrollable had the man survived longer".

This is a very singular statement. If the condition of the artery were really as described, how is it that uncontrollable and probably fatal hæmorrhage did not take place during life? There was nothing whatever to prevent it. Mr. Bradley then says he thinks the case "goes far towards establishing the correctness of the opinion that catgut is an unfit agent for securing arteries in their continuity". In what way does it show that the condition of the artery would not have been as bad, or even probably worse, if silk had been used instead of catgut?

Next, we are told that "catgut is efficient and safe in deligating the vessels severed in amputation, for the reason that, the limb being removed, less blood is sent down the divided arteries, and so but little stress comes upon the encircling ligature (it is otherwise when a ligature is applied for the cure of aneurism), and, as a consequence of this, it yields, and so, permitting the re-establishment of the stream, prevents the formation of a coagulum". Where is the evidence that there is less stress upon the ligature after amputation? May it not be argued with more plausibility that, after ligature for aneurism, the blood speedily becomes diverted into enlarging collateral channels, and the stress is, therefore, diminished; whereas, after amputation, there is no necessity for this diversion, and, during the critical period, the full impulse continues to fall upon the point ligatured? At all events, in this case, it seems impossible that the ligature could have yielded so as to permit the re-establishment of the stream without causing fatal hæmorrhage, if it had, as we are told, completely cut through all the coats of the vessel, with the exception of a short interval.

It has long been taught—and the teaching is as true as ever—that, when an artery is properly tied, the internal and middle coats, being brittle, are cleanly cut through, while the external coat, being tough, is gathered up into a cord within the noose of the ligature, and forms for a time a sufficient barrier to the escape of blood. Plastic effusion then soon takes place from the divided ends of the inner coats and into and around the tissue of the constricted outer coat; coincidentally with which a coagulum is formed above and below the ligature, unless this is prevented by the proximity of some large branch or by some abnormal condition of the blood itself.

When both these processes are complete, there is little or no risk; but, if no coagulum form, safety must depend entirely upon the perfect and speedy organisation of the plastic material. The question arises, therefore, whether this adhesive process will be best promoted by the use of catgut or of some other material, such as silk or twine.

I believe carbolised catgut to be preferable, for the following reasons. It does not cause local irritation; it is capable of gradual solution and absorption, and its ends may, therefore, be cut off short. It has the same immediate effect upon the coats of the vessel as other materials, and, if of sufficient thickness, it will hold long enough for the natural hæmostatic processes to take place, while it will, in most cases, be dissolved without ulcerating through the external coat. Silk or twine, on the other hand, are in themselves irritants; being insoluble, they can only escape by ulceration and its attendant suppuration, processes essentially antagonistic to the perfection of adhesive union. To insure the exit of the ligature, it is necessary to leave one end protruding through the wound, and this serves not only to keep up a communication with the outer air, but to conduct pus or other morbid secretions from the superficial parts directly down to the tied artery itself, which can never, therefore, so long as the ligature remains, become completely surrounded by a sheath of adhesive lymph. This may be comparatively unimportant when a good coagulum forms; but I submit that, in those dangerous cases where the coagulum is absent or imperfect, it may sometimes make all the difference between life and death. My own experience in fifteen cases, referred to in the *JOURNAL* of November 10th, 1877, is entirely favourable to the catgut ligature. No untoward accident referable to the ligature occurred in any of them; and, in three instances where I had the opportunity of examining the vessels after death, I found the deeper parts of the wound securely closed and protected by reparative material, although diffuse suppuration or sloughing was going on nearer the surface.

Catgut requires more care in its application than silk, or the first knot may easily slip while the second one is being tied; and, to insure complete safety, a third knot should always be made. Is it not most probable that, in the cases in which the circulation has been re-established in the vessel shortly after operation, the knot has not been tied with sufficient care, and has opened out under the pressure of the current of blood. It is most unlikely that such an accident should happen with a ligature of sufficient thickness, if it be tied tightly enough to divide the inner and middle coats, and securely enough to prevent all risk of its slipping.

JAMES R. LANE, F.R.C.S.

#### CATGUT DRAINS.

IN the *JOURNAL* of March 9th, Mr. Bradley states that a skein of catgut ceases to act by capillarity when it becomes saturated "by the contiguous fluids". This statement appearing inconsistent with the laws of capillarity, I was led to investigate the question, and, after repeated experiments, I found that, on the contrary, the more thorough the saturation the more perfect the drainage—a skein of catgut proving as effective a drain at the end of four days as after thirty minutes. Of course, if a narrow vessel be used, the surface will fall considerably in a few minutes, thus decreasing the flow, owing to the increased work required to raise the water over the edge of the vessel; and, in such a case, it is evident that the flow would cease entirely when the amount of work required became equal to the capillary force.

PATRICK M. PLAYFAIR, The University, Edinburgh.

#### CLEANING CATHETERS.

THE plan proposed by Mr. Davy in the last number of the *JOURNAL*, for cleaning catheters by drawing a bristle through them, has much to recommend it. But it is an objection to such a plan that it is not applicable to the catheters usually made, with openings or "eyes" at the side, at a distance from the point. For many years, I have found that I could clean catheters sufficiently by using the common wire stilet, having the end twisted into a small eye, through which a thread is passed, or a piece of string, according to the size of the catheter. The wire should be long enough to reach to the tip of the catheter. By

moving this backwards and forwards as a piston, in a basin of warm water, the remains of the urine or other matters within the tube are effectually pumped out through the eyes at the side. About twenty-five years ago, I had a set of catheters made, with the wire stilet for each one having an eye at the point. With these, the catheters can be cleaned without much trouble. In some cases of retention of urine, I have found this kind of piston or pumping action useful in withdrawing the contents of the bladder when distended with blood, or in cleaning the catheter when the tube is plugged by a clot.

E. L. HUSSEY, Oxford.

## REPORTS AND ANALYSES

AND

### DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### GROUT'S PATENT INFANTS' FOOD-WARMER.

WE have recently had the opportunity of testing one of Grout's "Food-Warmers", and now bring it before our readers as likely to prove of inestimable value to all mothers and tenders of invalids. It consists of a double box to contain boiling water, having in its interior room for two or three bottles, and closing with a padded lid. When the apparatus is filled, the bottles with the milk or food *cold* are placed inside and the lid closed; it quickly becomes warm, and will keep so for twelve hours; so that the nurse finds the milk quite ready to give to the infant at any time in the night.

Some of the advantages are, that there is no expense of night-lights, etc.; it requires no attention in the night; and the food never gets burnt. It can also be used by day, thereby obviating the need of a nursery fire. The warmer cannot get out of order, and can take any ordinary feeding bottles. Another advantage will be its great utility in long journeys. Three bottles can be placed in the box, which is easily carried by its handle, and so the infant can have its regular food throughout the journey without any trouble. For invalids also, the food-warmer will prove most useful, for the divisions can be taken out and any larger vessel put in the box, and food, such as beef-tea, etc., kept hot all day. The prices vary from 10s. 6d. to 25s.; and it can be obtained of Swan Nash, 253, Oxford Street.

#### NEW MEDICINAL PREPARATIONS.

MR. MARTINDALE, pharmaceutical chemist, of 10, New Cavendish Street, Portland Place, has forwarded us several valuable specialities prepared in his laboratory. Among them, we would particularly draw attention to a solution of the alkaloids aconitia, atropia, morphia, and veratria, in oleic acid. This is rapidly absorbed, and forms a strong anodyne liniment, which can be diluted by the addition of rectified spirit or oils. It is supplied under the name of *oleanodyne*. The glass capsules of nitrite of amyl encased in silk, containing one, two, and three minims, are an ingenious mode whereby this volatile but valuable therapeutic agent may be employed. When used, all that it is necessary to do is to take the ends of the capsule between the thumb and forefinger of each hand, snap it in the centre, and inhale. He also forwards us a novel preparation in the shape of salicylate of iron, presented in the form of a purplish powder. This drug might be usefully administered in debility after rheumatic or arthritic attacks.

TREATMENT OF ERYSIPELAS BY SILICATE OF SODA.—Dr. Alvarenga of Lisbon records forty-eight cases of erysipelas of the scalp, face, and limbs, both fixed and erratic. He asserts that with the aid of the above mentioned remedy the disease does not last more than four or five days. The silicate of soda—the same that is used for immovable apparatus—is diluted with eight times its weight of distilled water, and neutralised when it is acid with soda. The solution is spread with a brush morning and night on the affected parts, and allowed to dry in the air. After four or five days, when the fever, tumefaction, and redness have diminished, the use of the silicate is suspended, and the affected parts are covered with wadding steeped in oil of sweet almonds.

## BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

## BRITISH MEDICAL JOURNAL.

SATURDAY, MARCH 30TH, 1878.

### PHYSIOLOGICAL TEACHING AT TRINITY COLLEGE, DUBLIN.

WHEN, either by accident or design, an important medical school, educating a large number of students and officered by a full staff of accomplished professors, is placed in such a position that the most elementary instruction in practical and experimental physiology cannot be given within its walls, it becomes a matter of serious regret from an educational point of view. When we add to this that not one of its professors can undertake any original research within the institution with which he is connected, involving any observation on an animal which the most sensitive person could suppose to be calculated to give pain, it may be said to be still more depreciated in value scientifically. Such a medical school can educate students of medicine but very imperfectly; it can add absolutely nothing to human knowledge in a large department of chemistry, toxicology, therapeutics, experimental pathology, or physiology. It will seem almost incredible to say that this is the position to which the Medical School of the University of Dublin is now reduced by the deliberate act of its own professors, accomplished, if we are rightly informed, by a casting vote of one.

As our readers are aware, the Act which passed in 1876 to regulate experimental researches on animals practically requires that such researches shall be carried on only in certain places registered by the Home Secretary (or in Ireland by the Chief Secretary to the Lord Lieutenant); otherwise no efficient supervision or control could be adopted by the inspectors, and the Act becomes inoperative. Whether it be for original research or for purposes of instruction, it is necessary that some apartment to which the inspector can at any time have access shall be "registered". Unless this prime condition of the Act be complied with, no original research can be undertaken; neither can even the most elementary instruction, such as showing the circulation in the web of the frog's foot, be given legally to students.

This step as to the registration of lecture-rooms or laboratories has been taken in London, at Oxford, at Cambridge, at the Scotch Universities, and at some of the medical colleges in Dublin. In fact, a considerable number of our most important medical educational institutions have shown a disposition to meet the authorities fairly, and co-operate in carrying out an Act of Parliament framed in a spirit of extreme humanity.

About a fortnight since, the Council of the University of Dublin passed a resolution to the effect that it was desirable that some places within the University or its medical school should be registered under the Act. The question was at a later period referred, as we are informed, to the professors of the medical school for their consideration. Whether from a natural disposition to recalibrate against laws passed by "the English House of Commons", or from timidity lest they may be assailed by the "anti-vivisectionists", the professors have by a majority of one expressed an opinion against the desirability of having any place registered under the Act.

Inasmuch, therefore, as the authorities have declined to register any private house or private laboratory, the medical professors of Trinity College, Dublin, have placed themselves and the medical school in which they teach in this absurd position. Not one of them can insti-

tute any original research in any of the subjects already spoken of; nor can they demonstrate to their pupils the most elementary phenomena connected, for instance, with the circulation of the blood. It is not a question of vivisection, but of any experiment or research relating to antidotes for poisons, dietetics, animal chemistry, therapeutics, etc. Whatever may be the reasons which have prevailed in bringing about this decision, it has placed the institution in a most unenviable position of retrogression, and most painfully lowers its position among medical schools, not only in the United Kingdom, but throughout the world. Indeed, it may be expected that some of the more intelligent students will themselves take the matter up and petition the ruling authorities not to allow the teaching of biological science to be so completely extinguished in Trinity College, as it must be if nothing be done to fall in with the law as it at present exists; otherwise they would have to look to other schools for the education which they cannot obtain in that which should be, and in many respects is, a model school. As regards original research, it seems a hard case that really able and earnest men like Professors Emerson Reynolds, Purser, and Macalister should be prevented by those who may take less interest in the progress of scientific medicine from pursuing inquiries and adding to necessary knowledge, in a manner worthy of the country and university to which they belong, by being prevented from engaging in original biological inquiry in scientific medicine and the ancillary subjects. A medical school which has not complied with the terms of the Act is not one in which physiology can be taught efficiently, and from this point of view it may be doubted whether the licensing bodies are justified in recognising its physiological teaching or accepting its educational certificates. This is a point of view which concerns also the General Medical Council. That body meets on April 10th; and it may be the duty of those who warmly disapprove and view with deep regret the course adopted (among whom, we understand, are some of the most eminent members of the University), to bring the subject formally under the notice of the Council, where it can be adequately discussed from all points of view. We hope that meantime all sides of the subject will be duly weighed, and the decision brought under review, when we think it would be felt that an unwise course has been adopted, which it is not too late to retrace.

### RECENT RESEARCHES ON INFLAMMATION.

WE have lately placed before our readers the results of investigations into the nature of the inflammatory process recently undertaken in the laboratories of Virchow and Stricker; the object of study in the one case being the inflamed bronchial mucous membrane; and in the other, inflamed tendon. It may be convenient to complete our references to the subject by calling attention to some of the latest work done in the now well-beaten field of keratitis.

When a frog's cornea is cut out and placed entire in the field of the microscope, being a transparent and not very thick object, it can be examined throughout its whole depth with a fairly high power. By moderate staining, large nuclei can be seen in its substance. If an inflamed cornea be subjected to the same treatment, it is to be supposed that any changes which take place in the nuclei or the granular substance that surrounds them—histologists not yet being agreed as to whether this latter is cellular or an amorphous precipitate—will become apparent; and if any cells exist in the inflamed cornea which do not exist in the healthy structure, that it will be easy to trace not only their presence but their source. This apparently satisfactory object of study has, therefore, become classic, but the results are widely different from those which one might at first sight be induced to expect; for there is nothing that has been described in the inflamed cornea by one pathologist that has not met with direct contradiction from some other. Let us take, as an example, a point that might seem capable of an easy and definite solution—the fate of the large flattened nuclei so easily demonstrated in the cornea. Although Ranvier described, a

few years ago, a new method by which in keratitis the division of these nuclei into several round smaller bodies could be satisfactorily shown, we have quite recently Mr. Dowdeswell stating, as the result of some painstaking studies in the laboratory of University College (*Proceedings of the Royal Society*, vol. xxv, p. 390), that "the most careful scrutiny of his preparations fails to detect any difference whatever as regards their forms or aspects, between the fixed corpuscles of inflamed corneas and those of normal corneæ prepared in a similar way"—nuclei, of course, included. And for the further confusion of students of pathology, we find Cohnheim and Stricker (the two foremost representatives of the diametrically opposite opinions held regarding one of the chief phenomena of inflammation, the origin of pus-cells) engaged in bringing out important works on general pathology, in which their irreconcilable opinions are consecrated and perpetuated. Stricker (*Vorlesungen*, 11 Abth., Vienna, 1878) lays it down as indisputably proved by a long series of observations that the nuclei of the cornea and the granular network in which they seem to be imbedded, under the "stimulus" of inflammation, "proliferate" into new cells. Cohnheim, on the other hand (*Vorlesungen*, Band 1, Berlin, 1878), maintains that "we are still a long way off any proof that pus-cells originate otherwise than as emigrated colourless blood-corpuscles; and that the most that can be said is that pus-cells probably increase in number by undergoing division". The opinions of both these authorities are supported by numerous followers; the sides on which the latter are ranged being evidently determined, in the majority of instances, by the spirit that prevails in the school or laboratory in which they have carried out their investigations.

An examination of the memoirs in which their researches are recorded shows that there is still much uncertainty attending many of the methods employed by pathologists in these inquiries. It is only thus that we can explain how the persevering and conscientious labours of so many workers fail to secure unanimity on even the elementary questions that are involved. To take some examples which may illustrate our meaning: Walb found that solution of carmine can be injected into the living cornea without producing much acute inflammation, and that at first the cornea corpuscles (that is, the nucleated network) are stained. After some time, red carmine-coloured giant-cells are found in the network; and it seemed reasonable to infer that the giant-cells resulted from a proliferation of the corpuscles. But Senfleben observed that, when carmine is injected into a dead rabbit's cornea and the latter is placed into the peritoneal cavity of a living rabbit, the same giant-cells are formed; and he thence concludes that they are formed by the massing together of colourless corpuscles from the living animal, which enter the interstices of the dead tissue. We may add that it is evident that a third explanation is not excluded, so long as the process of their formation is not followed in all its stages.

Amongst the more noteworthy of these later experiments may be instanced those described by Dr. Ernst Fuchs in Virchow's *Archiv*, 1876. In order to test whether certain nuclei found in the inflamed frog's cornea are due to proliferation of fixed corpuscles, or are migratory colourless blood-cells, he excised the corneæ of living frogs, cauterised them after they were excised, inserted them in the anterior chamber of the eyes of pigs removed from animals recently killed, and closed the incision by which they were inserted. After they had remained in this cavity for various periods he observed, on examination, that a much greater number of nuclei were visible in the frog's corneæ so treated than are usually seen in the frog's cornea; and in addition, evidence that there are various kinds of cellular elements in such corneas was obtained. Dr. Fuchs infers that the excised and cauterised frog's corneæ (cauterised after being excised, it is to be remembered) became inflamed in the chamber of the pig's eye, and that all extraneous sources from which the numerous cellular elements seen

could be derived being excluded, the corpuscles had proliferated. Without raising the question as to the propriety of applying the term inflammation to any possible changes that may take place in an excised cornea placed in a dead eye, a critic might with much reason object to the imperfect scope of the investigation. Before laying any weight on the appearances seen in the excised and cauterised cornea, we should first have a series of observations on frogs' corneæ excised and placed in pigs' eyes without being cauterised, and also on the corneæ of entire frogs' eyes similarly treated. The fact seems to be, that the appearances visible in an inflamed cornea depend, to a greater degree than seems yet to be generally appreciated, on the agent used to produce inflammation, and on the methods by which the cornea is prepared for examination. Whilst in a cornea moderately inflamed by nitrate of silver or a fine seton, then excised and stained by gold, such nuclei as are preserved are usually seen entire (Mr. Dowdeswell, in twenty corneæ so treated, did not find the nuclei divided in one, although, even in gold preparations, such division has been observed and figured by several histologists), in corneæ punctured and stained in purpurine (Ranvier's method) the division of the nuclei into smaller pieces is easily observed. Whilst in gold preparations the beautiful purple network described as the "corpuscles" comes out in even exaggerated relief in the various stages of inflammation produced by nitrate of silver or a seton, on the other hand, a cornea cauterised by caustic potash, excised and stained in silver, and afterwards allowed to swell in acidulated water, shows an appearance of a totally different kind. In the latter case, instead of a network of finely granular matter, we have a network formed by the juxtaposition of numerous small epithelioid cells, and in the central or nodal points patches of such cells, several cells in breadth.

Stricker, in the volume to which we have referred, represents this appearance in a coloured plate. The cellular elements shown are similar to those figured by himself and his pupils at various times during the last seven years. This newest representation illustrates a very successful preparation of a cat's cornea inflamed from twenty to twenty-four hours; and is described as the "cell-network divided into small nucleated fractions". It would, indeed, be difficult to imagine that in twenty hours' inflammation, the colourless blood-corpuscles which enter the cornea could arrange themselves in the regular epithelioid fashion which is here portrayed, and have all of them acquired the same exaggerated and uniform size.

We should not omit, in this connection, to recall the fact that Dr. Thin has explained this appearance on the theory that the destructive action accompanying inflammation of the cornea so alters the tissues that cell-outlines, always present but not usually seen in silver preparations, become visible; and Dr. Klein appears quite recently to have taken a similar view. In a note in the *Quarterly Journal of Microscopical Science* for 1877, after confirming the appearances described by Stricker as obtained by silver-staining corneæ which have been inflamed by caustic potash, he remarks that the method "demonstrates the normal structure in an exceedingly beautiful manner". But we must not forget that Stricker himself countenances no such view, and considers the appearance as strictly pathological.

#### THE MEDICAL DEPARTMENT OF THE ARMY.

THAT Parliament and the press continue to evince an interest in the affairs of the Army Medical Department, is a healthy sign of the times. It may be safely asserted that no branch of the military service is, at this moment, so unfit to bear the least strain of war. Indeed, it is but too painfully manifest that its present weakness is such that, at one of our largest military stations, not ten miles from London, there has just been a serious breakdown of the department, owing to a glaring insufficiency in the number of medical officers required for the perform-

ance of the ordinary routine duties of the garrison. This is a fact, the full details of which are now in our possession. The civil practitioners of Woolwich having been appealed to, these gentlemen are doing their best "to keep things going". But to any one acquainted with the nature of the duties devolving upon army surgeons, it will be at once apparent how, with such hasty and crude arrangement as this, the physical efficiency and *morale* of the troops can hardly fail to be less or more injuriously affected.

We are not now going into an analysis of all the causes leading to the occurrence of this ominous incident. Suffice it to say, in the meanwhile, that, when in the seemingly desperate but futile attempt "to save appearances", to obviate alarm and hide the woeful dearth of army surgeons, the senior surgeon-majors are being forced to execute the most subordinate duties of the department, hitherto always discharged by the subaltern ranks, the actual condition of this service may at least be imagined if not quite realised. And all this, and much more equally bad, is happening at Woolwich and all over the United Kingdom, at the Cape, in our other Colonies, and in India; whilst Mr. Hardy assures the House that there are only eight vacancies in the Army Medical Department!

What must happen were we to be immediately embroiled in a great and prolonged European war? What but disaster as regards the Army Medical Department? And what else? Well, should such be the probable fate of that department *ut nunc est*, concerned as it is, with the maintenance of the physical efficiency of the army and of much of its *morale*, the "what else", it requires no prophetic gift to foretell.

"The Bare Statement" which we recently republished cannot receive a too careful study from those who may now be investigating the condition of the medical department with a view to the necessary remedies being speedily applied. This statement, in a somewhat less comprehensive form than its present, was first published by us nearly a year ago; and since that time, we have had ample opportunity of judging as to its correctness. It is of no use any longer wilfully ignoring the fact, that the Army Medical Department is the subject of serious organic disease as well as of grave functional disorder. This is an undoubted fact, and one which no keen-eyed and wise observer, anxious for its restoration to health and efficiency, can possibly fail to perceive and admit. The *Army and Navy Gazette* thinks that it may be the want of "feathers, belts, and lace" that is playing the mischief with the department. The *Daily Telegraph* says that the army-surgeons are always making "a fuss about trifles". Mr. Hardy, after nearly four years as War Minister, cannot see what these gentlemen have to complain of. He has, however, appointed a small committee to inquire and report. This committee is of such purely official constitution, including Sir W. Muir as its sole medical member, that it has not commanded general confidence: it has, however, recognised the gravity of the situation, and is making such extended inquiries among the schools and in the service as will, we hope, lead it to wise conclusions. At any rate, we shall hope for the best.

It is announced that yellow fever is extremely prevalent at Rio de Janeiro.

THERE is some reason to believe that the College of Surgeons and the College of Physicians of London will resolve not to proceed with their conjoint scheme, unless the Government Bill for the Amendment of the Medical Acts be so modified as to make it compulsory on the examining bodies of Scotland and Ireland also to frame and carry into effect conjoint schemes for minimum examinations.

WE understand that the Council of the Pathological Society have it in contemplation to fill up the number of vacancies in the list of honorary members of the Society. The additions will, as is usual, be carefully selected from foreign medical men of eminence. The question of adding the names of one or two eminent Englishmen has also been mooted.

DR. HOWARD of New York gave a demonstration, at St. Mary's Hospital, in the operating theatre, of his method of restoring animation by artificial respiration, on Tuesday last, at 3 P.M. His method has been much approved by many eminent medical men. We are preparing for publication an illustrated report of it.

THE Council of the Metropolitan Counties Branch is taking active steps towards the formation of district sections, with a view to supplying the wants of the outlying suburbs of the district in the way of scientific and social medical organisation. We some time since urged this course upon the Branch, and the scheme was then taken up, but allowed to drop. It has now been revived, and is being carried through with so much vigour and judgment, as to have been speedily brought into working shape. Districts will be formed in the north, east, south, and western parts of the extensive and thickly populated territory of the Branch. There are about 1,200, we believe, members of the Association within the districts, or about one in every two members of the profession. Local secretaries have undertaken to act, and a scheme of organisation has been prepared, which is based upon that efficient plan in operation in the South-Eastern Branch, to which we have often had occasion to refer. By this plan, all the districts are supplied with local centres for scientific and social meeting, and the activity and efficiency are developed of the fertile principles of professional association and of local self-government which underlie the prosperity and usefulness of the Association.

At the last meeting of the Council of the Metropolitan Counties Branch, an appeal was read from the Harvey Tercentenary Committee, of which the like has, as we have announced, been addressed to all the Branches, and we believe also to the Committee of Council of the British Medical Association, as well as to all the medical corporations and universities. The Metropolitan Council unanimously voted a sum of ten guineas from their funds; an example of judicious, if restricted, liberality which will probably find many parallels in the other similar bodies which have been addressed.

Two new wards, each containing twenty-four beds, have been opened in the Hôtel-Dieu, Paris. The two clinical professors, whose courses of lectures have been interrupted since the opening of the new hospital, will now be enabled to resume them.

THE preliminary report of the Pyæmia Committee of the Pathological Society has been forwarded to the Local Government Board, who, it will be remembered, have made a Government grant towards the expenses of the investigation; and it is also expected that the Committee appointed to report on the conditions and pathological changes in the vessels in Bright's disease, will do so before the end of the session.

THE last meeting of the Pathological Society, of which we publish a report in another column, was one of very great interest, and in every way worthy of the new phase of scientific activity on which the Pathological Society has entered during the last two years with much vigour and success. The complaints which we formulated just before that time on several occasions, that the proceedings of the Society were rather those of an anatomical society which discussed purely dead-house specimens in a disconnected and unscientific spirit, was followed by a very speedy reform under the auspices of Dr. Marchison, which has placed the Society in the foremost rank of active scientific working bodies. The discussion at the last meeting bore upon the pathological conditions and processes belonging to the lymphadenoma, or as Dr. Gowers proposes that the state in question shall be called, lymphadenosis. This obscure and surgically interesting condition is still very imperfectly understood, and is by some pathologists still considered as though it were synonymous with leucæmia. The extremely interesting communications of Dr. Wilks, Dr. Greenfield, and Dr. Gowers, throw a great deal of light upon the pathological conditions and processes connected

with lymphadenosis; and it is a specially notable point in Dr. Greenfield's communication that, in all but one of the series of cases which he brought forward, there was nothing like a condition of leucocythæmia.

THE President of the Royal College of Surgeons has summoned an extraordinary meeting of the Council for Monday next, to consider of the Government Bill for the Amendment of the Medical Acts.

THE Council of the Pharmaceutical Society proposes holding a *conversazione* at the South Kensington Museum in May next.

THE many friends of Dr. Black of St. Bartholomew's Hospital will sympathise with him in the irreparable loss he has sustained by the death of his son, Lieutenant W. E. Black, in the foundering, on Sunday last, of H.M.S. *Eurydice*; on which occasion, Staff-Surgeon James Leech Whitney and Surgeon Robert Murdoch also perished. This is the second son whom Dr. Black has devoted to and lost in the naval service of the country. Surgeon Murdoch was a member of the British Medical Association.

THE Crown Prince of Austria has caused a letter to be sent to Professor Flower to express His Royal Highness's best thanks for the services rendered by the Professor during his visits to the Museum of the Royal College of Surgeons of England.

THE MEDICAL ACT AMENDMENT BILL AND THE TITLE OF DOCTOR. WE have before pointed out the hardship inherent in the present state of things as affecting the students of the metropolitan schools and diplomates of the London examining bodies, by the recent decisions of the Royal College of Physicians of London. A person who has studied in the metropolitan schools, and availed himself of their great opportunities of teaching, and has subsequently obtained a diploma of the three principal licensing bodies of the metropolis, and has thus become fully qualified both as a physician and surgeon, is debarred from the use of the title of Doctor. That title, however, is the rightful appanage of the graduates of the principal licensing bodies of Scotland and Ireland, and also of the graduates of the Queen's University in Ireland. It is not generally contended that by reason of the education of, say, the graduates of the Queen's University, or of the University of Durham or of St. Andrew's, they are more perfectly equipped as medical men than are the students of the London and provincial schools, who become diplomates of the three great licensing bodies of England. Nevertheless, it results from the present state of things, that whilst the great majority of medical men licensed in Ireland and in Scotland achieve a legal claim to the title of "Doctor", those who are educated in the great centres of England, whether at London, Manchester, Liverpool, Bristol, or other schools, have no opportunity of acquiring that title, and have thus far an official, and possibly often social, disadvantage as compared with their more fortunate Irish and Scotch brethren. We are inclined to think that, in any general revision of the scheme of examinations for the three kingdoms, such as is at this moment under consideration, some regard ought to be had to the subject of the grievance which has been discussed in our columns, by which the great proportion of English medical men are debarred from the use of the title of "Doctor".

#### FEEES AT THE LONDON SCHOOLS.

THE course which the teachers attached to the metropolitan schools propose, of raising considerably the fees for the course of medical teaching, is very naturally prompted by the steady increase in the cost of teaching inevitably attached to the improvement in methods and the extension of subjects in modern medical education. This cost is likely to go on increasing rather than diminishing. The expense of material and apparatus for histological and practical classes in all the subjects of scientific medicine, and the improved system by which students are now required to study facts and learn manipulations, instead of merely sitting on benches and gazing at diagrams while the amalgamated con-

tents of collated text-books are poured into their ears, involve considerable outlay in increased supervision of studies, as well as materials and instruments of work. Nevertheless, we may point out that this determination may have an unfortunate influence on the future of the London medical schools. If this "unsurpassed" system of teaching rise to the highest standard of cost, of difficulty, and of intellectual labour, while, as a result, its acolytes, when duly qualified, are still not technically "doctors", while the more cheaply equipped graduates of other schools are duly dubbed with the magic title to which so much importance is attached, and while a perfect reciprocity of practice is granted to the practitioners of Ireland and Scotland, it is to be feared that an increasing proportion of students of the English schools will prefer to seek those centres of education where they can consult economy and at the same time satisfy the longing for the higher title.

#### NON-COMBATANTS.

THE *Golos* publishes a telegram from their correspondent at Adrianople despatched on the 12th instant, stating that an entire sanitary corps of doctors, consisting of twelve persons, has been swept away by typhus, and, owing to the excessive mortality among the remainder of the medical staff, many of the sick and wounded have been left without attendance. The hospitals are full, and two thousand typhus patients are billeted upon the townspeople. Thirty-five doctors were sent from Warsaw and twenty from Odessa to take the places of the victims to the fearful epidemic which is raging. We referred lately to the statistics of the excessive mortality among the medical officers of the British army, and this report emphasises the perils of "non-combatant" medical officers in a very striking manner. It may be observed that the notice in the *Golos* is made to speak of medical officers as though they were "stores" to be shipped off to order; and, in fact, another telegram states that all medical officers have been requisitioned *en masse*, and forwarded to the fever-stricken districts of the war.

#### THE CASE OF THE REV. A. J. DODWELL.

THIS case is likely to cause much discussion in legal as well as medical circles from its peculiar nature. It frequently happens that a man is brought in by a jury as of unsound mind and the verdict subsequently set aside, but we do not remember where, after the jury have pronounced a man irresponsible for his actions, that the verdict has been over-ruled. The question is, what will the Government do with Mr. Dodwell? Dr. L. Forbes Winslow and Dr. Winn have seen him twice, and sent in their report to the Home Secretary, stating that they could detect no symptoms of insanity. It appears that the conduct of the accused during his residence in Newgate has been exemplary and most rational. He premeditated for some months the act for which he is now suffering. He is indignant at the question of his sanity being raised, and complains of being pronounced as *non compos mentis* without any medical witnesses having been called to support such an allegation, not even Mr. Gibson, the surgeon of the gaol. He considers that anything is more preferable than to be stamped as a criminal lunatic and incarcerated as such for life in a living tomb. He entirely repudiates any intention of having contemplated murder. He is a man of determined purpose; and if he have once taken an idea into his head, he will endeavour to carry it out to the utmost of his ability. He had written several letters to the authorities, stating that it was his intention to break the law in order to have his case properly discussed in the Court of Appeal. He appears to have been driven to desperation and ruin by what he considers to be an injustice. He does not labour under any delusion. He occupies his time in Newgate in writing Latin poems, being a man of highly cultivated and classical attainments.

#### UNAUTHORISED DEATH-CERTIFICATES.

THE national death-register, since the Births and Deaths Registration Act of 1874 came into operation, affords most valuable, although indirect, information as to the amount of unqualified medical practice in different parts of the country. At the present time, this subject has an exceptional interest. The death-register shows how many causes of

death are certified by registered medical practitioners, how many by coroners, and how many are uncertified. Causes of death are uncertified from three causes: either because the deceased person has been attended by a qualified but unregistered practitioner, these cases being but few; or because the deceased has been attended by an unqualified practitioner; or because the deceased has died without any medical attendance. The proportion of the latter cases varies in different localities, and is, of course, largest among the lowest classes in large towns and in very sparsely populated districts, where the distance from the nearest medical practitioner is often very great. As a rule, however, except in such districts, it may be generally assumed that, if the proportion of uncertified deaths exceeds 2 or 3 per cent., it arises from the fact that a considerable proportion of the medical practice is in the hands of unqualified practitioners. We have recently had occasion to examine the death-register of Dartford, Kent, for example, and observed that more than 10 per cent. of the causes of death are uncertified. Now, in such a district, it is impossible to suppose that many persons die without medical attendance; and, on inquiry, it appears that there is in Dartford a person who styles himself an "eclectic physician", and, moreover, assumes the title of "Dr.", who has a considerable practice, and in cases of deaths among his patients furnishes a printed certificate of the cause of death to the relatives, who take it to the registrar. This cause of death is, in accordance with instructions, entered in the death-register as an uncertified cause of death. Under the present state of the law, the difficulties in the way of prosecuting such an unqualified practitioner are well nigh insuperable; and, unless the local coroner could be persuaded that a few inquests in such uncertified cases would be useful, at any rate in informing the public that such and such a practitioner is unqualified, the attempt to suppress such practice seems hopeless. It is to be hoped that the provisions of the new Medical Act Amendment Bill will supply a better remedy for the evils of unqualified medical practice than at present seems probable.

#### TOO MUCH ZEAL.

AN unpleasant occurrence has taken place at the Paris Faculty of Medicine. By the rules, the students are forbidden to take away any parts for dissection; but notwithstanding this formal regulation, several parts had disappeared from the dissecting-rooms of the École Pratique. The Academical Council met and decided to remind the pupils of the regulations on this point by placards affixed to the walls; and at the same time, the curators had orders to look better after the students. A few days afterwards, a student was taken in the act. M. Vulpian, the dean, after having consulted the Academic Council, has expelled him and announced the fact to all his fellow-students by placards in the École de Médecine and the École Pratique.

#### SPONTANEOUS GENERATION.

M. COLIN read, at a recent meeting of the Paris Academy of Medicine, an interesting paper on the successive development of virulent foci during the incubatory stage of anthracoid diseases. His conclusions, if accepted, would overthrow the theories of M. Pasteur, whose admirable experiments on anthracoid infection are well known to our readers. M. Pasteur, consequently, proceeded to make a vigorous attack on M. Colin's paper, refusing to receive his conclusions on the ground that the experiments of other workers have no value if they are not conducted according to M. Pasteur's method. Finally, M. Colin asked for a commission to verify the facts advanced by him; and the Academy appointed MM. Pasteur, Colin, Bouley, Davaine, and Vulpian, to report on the results submitted to them by M. Pasteur and M. Colin.

#### THE SUSSEX MEDICAL FRIENDLY SOCIETY.

THE twentieth annual report of the Sussex Medical Friendly Society, just issued, is very interesting, as showing the difficulties attendant on the establishment of such a Society, and the success that waits on persistent effort. The Society had its origin at the annual meeting of the East Sussex Medico-Chirurgical Society, held at Hastings on July 4th,

1857, at the instance of some gentlemen who were of opinion that considerable benefit would be likely to accrue from a local society founded on the principle of mutual benefit, on a plan similar to that followed by societies already then established in Kent and Surrey. By the end of the first year, the Society consisted of thirty members, and increased steadily until 1860, when it numbered thirty-nine. From various causes, such as the absence of novelty and the appearance of any good result from the funds subscribed, its numbers, in 1864-5, fell to twenty-five, and in June last the Society was composed of twenty-seven members. The part of the report relating to finance is very encouraging. The receipts from all sources amount to £966. The demands for relief have been few—only three in thirteen years just passed, and none previously to the commencement of that time. The sums expended in meeting those applications amounted to £320. The cost of management has been very slight indeed—only £61, or about £3 a year. The remainder of the sums subscribed have been invested. A proposition to transfer the centre of management to Brighton will be carried into effect, so soon as the numerous practitioners of that town shall have joined the Society.

#### TAMPERING WITH A PATIENT.

MR. JUSTICE LOPES, at the Lancaster assizes, recently passed the severe sentence of ten years' penal servitude on John James Coupe, lunatic asylum attendant, for inciting a man named Jackson, a patient at the Lancaster County Lunatic Asylum at Whittingham, to murder and rob two other attendants. For this purpose, he furnished the patient with a piece of sharpened iron, and taught him how it was to be used, arranging also time and place and the plan of Jackson's escape. Jackson fortunately related the whole affair to Dr. Holland, the superintendent, and in consequence Coupe was discovered in the neighbourhood under circumstances that left no doubt on Jackson's story.

#### THE GERMAN SURGICAL CONGRESS.

THE seventh congress of German surgeons will be held in Berlin on April 10th to 13th. At the last annual meeting, it was decided that discussion on malignant tumours should take place this year; and Dr. Thiersch undertook to draw up the necessary propositions. As, however, the propositions have not been received in time for distribution among the members of the German Surgical Society, Dr. von Langenbeck, as president of the committee, has decided that the discussion on the entire subject shall be deferred until 1879, and that at the forthcoming congress the following arrangement of subjects only shall be considered. 1. Etiology of tumours, and especially of malignant new growths: *a.* Heredity and congenital predisposition; *b.* Origin of tumours after chronic irritations and chronic inflammatory processes; *c.* Influence of other diseases on the origin and recurrence of tumours (psoriasis, eczema, acute exanthemata, lupus); *d.* Relations of congenital and acquired syphilis, and especially of syphilomata (gummata) to the formation of sarcoma and cancer; *e.* Origin of tumours in consequence of single wounds and injuries; *f.* The communicability of carcinoma; *g.* The relation of certain physiological conditions to the origin and return of tumours (pregnancy, lactation, puberty, uterine involution); *h.* Depressing mental affections. 2. Diagnosis of tumours: *a.* Ulcerated syphiloma and cancer; *b.* Syphilitic ulceration of the skin and mucous membranes, and cancer; *c.* Phagedenic chancre and superficial epithelioma. 3. The various degrees of malignity in the different anatomical forms of carcinoma and sarcoma, and according to their seat in the various organs and regions of the body. 4. Malignant course of growths, which at other times are held to be benign in a clinical sense (lipoma, fibroma, enchondroma). 5. Spontaneous cure of tumours, especially cancer (by absorption, calcification, or sloughing). 6. Duration of cure after removal of tumours with or without loss of blood: *a.* Permanent cure; *b.* Time of appearance of local return; *c.* Time of appearance of recognisable disease of the lymphatic glands; *d.* Time of occurrence of metastasis after operations for cancer; *e.* Do metastases occur more frequently and sooner, after or without

operation? 7. Results of treatment of malignant tumours: *a.* Influence of the method of operation; *b.* Influence of the treatment of the wound; *c.* Results of electrolytic treatment; *d.* Results of parenchymatous injections of non-irritant fluids; *e.* Results of the use of internal remedies; the dietetic treatment; *f.* Are there any remedies which, used locally, have a specific effect on the elements of the new growth, so as to destroy them without affecting the healthy tissues? 8. Contributions to the general statistics of tumours, especially malignant new growths.

#### MANCHESTER ROYAL INFIRMARY.

OUR Manchester correspondent writes:—Mr. Thomas Windsor has resigned the post of Ophthalmic Surgeon to the Manchester Royal Infirmary, which he has held for the comparatively short period of five years. He was the first to hold the appointment, and was induced to become a candidate at the general wish of a large body of the medical profession in Manchester. His rare skill and his profound learning render his resignation a great cause of regret, for certainly in many respects it will be almost impossible to fill his place. There are already several candidates in the field, amongst whom is Mr. E. A. Birch, who has for some time been Mr. Windsor's assistant at the Infirmary.

#### A LARGE HEART.

DR. SOURDES of Nancy obtained, at the medico-legal necropsy of a man who died suddenly, a heart which exceeded in size and weight all the recorded instances of *cor bovinum*. According to the *Revue Médicale de l'Est*, except in one case where the weight of the heart exceeded 1000 grammes (2 lbs. 3 oz.), the recorded weights have varied between 500 and 680 grammes (1 lb. 1½ oz. and 1 lb. 8 oz. av.). The one in question weighed, on the day of the necropsy, 1480 grammes (3 lbs. 4.2 oz. av.), and after it had been prepared and placed in spirits for some days it still weighed 1250 grammes (2 lbs. 12 oz. avoirdupois).

#### THE SUDDEN DISUSE OF STIMULANTS.

THE Reverend T. H. Chope of Hartland, North Devon, in writing to the *Times* on Monday, combats the general opinion that any sudden abstinence from alcoholic stimulants is injurious to health, especially if the abstainer be a person of advanced age. To support his statement, he instances an old widow, eighty-two years of age, who had through life been accustomed to drink gin and beer previously to her eightieth year. She suffered from occasional attacks of gout in her left hand, and also a running foot-sore. Two years ago, she adopted the total abstinence principle, with the result that the gout ceased to visit her and the foot-sore healed. Now, in her eighty-third year, the old lady is in good health.

#### HOSPITALS FOR OUR SEAMEN ABROAD.

FROM a recently issued Parliamentary paper, relating to the hospital accommodation for British seamen in Foreign ports, we learn that in some ports there is a hospital tax. This is sometimes levied for the support of hospitals established by the Government of the country, and in others for the support of hospitals founded either by the foreign residents or by a foreign Government in places where no native hospitals exist, or because of the insufficient accommodation afforded by the native hospitals. The ports are divided into three classes: 1. Where there is no hospital for seamen; 2. Where there is a native hospital; 3. Where the hospital is established by a foreign Government. In the case of the first, the medical attendance is limited to private practice. The charges are often heavy, and the skill of the practitioners uncertain. The native hospitals are often totally unfitted for British seamen, notably in South America, where the doctors are generally ignorant of the constitution of foreigners, and the religious bigotry of the directors mars the good which otherwise might be done. The British Government undertakes the protection of hospitals at a few ports, at many of which a tax has been successfully levied; at others, where there exists no power to tax, an attempt has been made

at voluntary taxation, but without success. In some instances, where the merchants and shipmasters lent their aid to the effort, it worked well; in other ports, with only a small foreign element, it has proved a failure. It may, therefore, be said that the voluntary system has failed, and that the self-supporting system without a guaranteed income has only been partially successful. Success alone has attended the hospitals supported by taxation where there is power to enforce it.

#### THE DISINFECTION OF THE LATE BATTLE-FIELDS.

ACCORDING to advices from Vienna, the Austrian Delegation on Saturday last unanimously adopted a motion to refer to the common Ministry a petition of the Association of Officials and various Insurance Companies, praying the Government to take steps for disinfecting the battle-fields of the late war. The Delegation at the same time requested the Ministry to use their endeavours to arrest, by means of an international understanding, the danger which threatens the general health of Europe from the vast number of corpses lying unburied in Roumania and Bulgaria, and with this view to take steps for immediately organising an international sanitary commission.

#### BERNOUILLI ON CROUPAL BRONCHITIS.

BERNOUILLI relates, in the *Deutsches Archiv*, vol. xx, a case of primary croupal bronchitis attacking a compositor, sixteen years of age, who had suffered as a child from scrofula and had the signs of stenosis of the mitral valves. After the patient had suffered for a long time from simple bronchial catarrh, and expelled daily three or four fibrous casts, there could only be discovered, in connection with this, one painful place on the left side below the axillary line, where *râles* were perceptible. After two or three days, these symptoms disappeared, but they returned again at the end of one, four, and eight weeks. These casts were thrown up especially during the night. Bernouilli has found the treatment of croupous bronchitis with inhalations to be without any success, and so also the treatment by emetics. He recommends that the patient be ordered to take deep respirations in order to excite the impulse to cough, and thus expel the casts mechanically.

#### PRESERVATION OF THE BRAIN.

M. ORÉ of Bordeaux employs the following method for preserving the brain. He removes the membranes with great care, and plunges the brain into alcohol, 90 deg. Four days afterwards, he passes pieces of cotton between the convolutions. The alcohol is changed every five days for twenty or twenty-five days. He then wraps the brain in three folds of linen placed one over the other and kept in place by India-rubber bands, and places it in a stove heated to 45 deg. or 50 deg. cent. (113 or 122 Fahr.) during fifteen or twenty hours, taking care to place the preparation in the lower part of the stove at some distance from the gas furnace which warms it. The linen envelopes are removed the brain is then covered with several coats of white India-rubber varnish. The brain thus prepared is then submitted to the galvano-plaster process.

## SCOTLAND.

THE winter session of the Scottish medical schools all ended this week, when the prizes were delivered, as usual, to the successful students in the various classes.

WE understand that Dr. P. Heron Watson, as one of the suite of the Earl of Rosslyn on his mission to the marriage of the King of Spain, has been made a Companion of the Order of Charles the Third.

AT a meeting of the managers of the Edinburgh Royal Infirmary, on Monday last, Mr. John Chiene was elected surgeon to the institution, in succession to Dr. Patrick Heron Watson, whose fifteen years' term of office has expired. This leaves a vacancy in the post of assistant-

surgeon, for which there are several candidates spoken of, among others, Dr. Cadell, Dr. P. H. McLaren, Dr. Bishop, and Dr. C. W. McGillivray.

#### EDINBURGH ROYAL MATERNITY HOSPITAL.

AT the annual meeting of the subscribers of this institution, the report read by the Secretary showed a most satisfactory year's work—206 patients were attended in the house, and 308 outside, at their own homes, with only one death, which occurred in a patient sent, in an almost moribund condition, from the Royal Infirmary. The report detailed the advance that had been made in the building of the New Maternity in Lauriston Place, of which it was proposed at present only to build the front and one of the wings, owing to a want of sufficient funds to complete the whole building immediately. It was anticipated that so much of the building would be completed and ready for occupation within a year from the present time. It was pointed out that one feature deserving increased support was the fact that the hospital is open to all women who apply, whether married or unmarried, and from any part of Scotland or elsewhere. The expenditure for the whole work of the year had only been £524.

#### DANGEROUS EMPLOYMENTS.

A REPORT has been published from Dr. Russell on a fatal case at Glasgow, in which he urges the probability that the disease from which the patient died was of foreign origin, communicated by the air in which she worked. Entering more fully on the subject, Dr. Russell urges legislative action in the matter of unhealthy employments, and states that, but for an accidental circumstance, within one week three adults, previously in perfect health, employed in one occupation, seized with illness and dying in a few days without medical attendance, admittedly from an unknown cause, would have been buried and their bodies placed beyond recovery.

### IRELAND.

A MAN named Woods died, on the 23rd instant, in the County Derry, at the advanced age of 103 years.

DR. WILLIAM FRANCIS MARA died at Athy, on the 23rd instant, of typhus fever, contracted in the discharge of his professional duties.

#### OVARIOTOMY IN IRELAND.

MR. LAFFAN of Cashel has added another to the list of successful ovariectomies in this country. He operated, on the 1st instant, upon a patient aged 36. The tumour was large, unilocular, and free from adhesions. Bichloride of methylene was used, and thymol spray employed. The case is reported as now convalescent.

#### CHARGE AGAINST DR. O'HARE OF BELFAST.

AT the Crown Court, Antrim, before Judge Lawson, last week, Dr. O'Hare, to whose case we lately referred, was indicted for forging a writ, and, pleading guilty, was sentenced to twelve months' imprisonment. The accused had become seriously ill since his confinement, and had been paralysed for the past month.

#### BELFAST WATER-SUPPLY.

AT present, there are about four and a half million gallons per day of water supplied to the town, which allows twenty-two gallons per head for a population of 200,000. It is expected that an arrangement will shortly be entered into between the Carrickfergus Commissioners and the Belfast Water Commissioners, in reference to the Lough Mourne and Copland scheme. When this is completed, together with the present works in course of erection, it is estimated that Belfast will have a total daily supply of between eight and nine million gallons, or thirty gallons per head for a population of 280,000. Regarding filtration, should circumstances require it, the Commissioners have taken steps to carry out the necessary works.

#### A FAIR WEATHER POLICY.

AT a recent meeting of the Drogheda Union Guardians, a communication was received from the Local Government Board, enclosing the return of Dr. Kelly for the quarter ending December 31st, and pointing out that no cases of vaccination occurred during all that time. The Board wished to know if there was any reason for this, or unwillingness on the part of the people to comply with the Vaccination Act. The only explanation suggested by the guardians was that the parties who had children to vaccinate were waiting for finer weather, which appeared to be considered sufficient excuse, as no action was taken in the matter.

#### TRALEE BOARD OF GUARDIANS.

AT a meeting, held on the 20th instant, a letter was received from Dr. Richard Harold, resigning his appointment as medical officer of Brosna Dispensary District, which post he had held for the past twenty-seven years, the duties being laborious, and requesting superannuation. If the district was, however, divided, he offered to become a candidate for a portion of it. The guardians have accepted his resignation, and we trust will grant him the retiring allowance to which he is so justly entitled after his long services.

#### CORK IMPROVEMENT SCHEME.

A LOCAL Government Board inquiry was held at Cork, on the 20th instant, by Dr. MacCabe, in reference to an application of the Cork Corporation to put the Artisans' Dwellings Act into operation, by clearing seven areas in the city for building purposes. Five of these areas are unhealthy, and the houses not fit for habitation; whilst the remaining two are healthy, but are included to make the scheme more comprehensive. The consulting medical sanitary officer gave evidence in support of the scheme, and stated that in many instances the houses were unfit for habitation, were not provided with the proper sanitary accommodation, and were overcrowded. Evidence was also given in a report of Dr. Curtis, furnished some time ago when he was dispensary medical officer for the locality, which, referring to a certain portion, stated that, whenever an epidemic occurred in the city, it always broke out there; that the houses were in a fearful condition, and dangerous to the occupants; that the sewerage was bad, and that it was an abominable pest-hole. He believed that, if the fever-hospital records were consulted, it would be found that there were more cases of cholera and fever admitted from that place than from any other part of the city. The cost of the scheme, including the purchase of the houses, removing them, opening up new streets and sewers, etc., has been estimated at £51,500.

#### ST. MARK'S OPHTHALMIC HOSPITAL.

THE governors have appointed Dr. Hudson, Physician in Ordinary to the Queen in Ireland, Consulting Physician to the Hospital, in room of the late Dr. Stokes. Dr. James Little, Vice-President of the College of Physicians, has been also appointed Second Consulting Physician in conjunction with Dr. Hudson; and Dr. Edward H. Bennett, Professor of Surgery in the University, Second Consulting Surgeon in conjunction with Mr. George H. Porter, Surgeon in Ordinary to the Queen in Ireland. Mr. Baker has been appointed Surgeon-dentist to the institution. All the above offices are honorary.

#### STEWART INSTITUTION FOR IMBECILES.

THE annual meeting of this excellent institution was held on March 14th in the Molesworth Hall, presided over by Lord James Butler, Vice-Chairman of Council. From the report of the Managing Committee we learn that the subscriptions last year amounted to £784 12s. 6d., being £128 os. 6l. beyond the amount obtained the preceding year; and the donations to £987 3s. 8l. The new buildings at Palmerstown are still in the hands of the contractors, but are approaching completion; and if the necessary funds are forthcoming, will most probably be ready for occupation in the course of the year. So many applications for admission of inmates of all ranks of society have been held

over, pending the completion of the buildings, that there is no doubt that the institution when ready will afford the means of relief to numbers of families, to an extent not contemplated by those who are unaware of the anxiety and care entailed by the existence of an imbecile or insane member. The Committee point out that, unfortunately, there are but too many of the inmates who, beyond kindly care, shelter, and protection, can derive but little benefit from being in the institution, and they desire to impress on the subscribers that it is the backward children, *les enfants arriérés*, those who are incapable of being taught elsewhere, and who suffer most from neglect and ill-treatment, who will derive most benefit from the ministrations provided for them in the institution, where they may be educated and sent out useful members of society, instead of being allowed to grow up in misery and degradation, to be the authors of crime and of misfortune to all who come into contact with them. Dr. Kidd, in seconding a resolution to sell the Lucan premises, with a view of helping on the completion of the new building by the money obtained, thought it could not too frequently be brought before the friends of the charity, that when they spoke of the educability of idiots they did not pretend that they could educate all idiots, or that they could restore any of them that were utterly idiots to an extent so as to be perfect individuals. But there was a large class of idiots who were not commonly looked upon as idiots, and in an institution such as theirs they could be educated in a manner impossible elsewhere, and could have their faculties so developed as to be quite capable of taking a place in society, and become useful and happy individuals, instead of being a burden to their friends and a source of mischief to society. There was an excessive proportion of hopeless cases, and he regretted that, when patients were voted for, the votes were not given for those who would receive the most benefit from the institution. Referring to the new building, he observed that they would be able to accommodate three hundred inmates; and in making the arrangements they were obliged, in accordance with the requirements of the Commissioners of Lunacy, to provide a certain amount of cubic space, which they had not exceeded. The expense of the building, he thought, would not exceed £80 to £85 per head for each inmate, which was extremely moderate. A vote of thanks to the chairman terminated the proceedings.

#### ABUSE OF DISPENSARY TICKETS.

AT the usual monthly meeting of the Queenstown Dispensary Committee held recently, the subject of certain visiting tickets issued by a member of the Committee was under discussion. On inquiry, it was ascertained that the parties who received medical advice and medicine in the cases complained of were not fit recipients for dispensary relief. It was suggested by several of the committee that the issuer of the tickets should be the plaintiff if the matter were brought into a court of justice; but no steps were taken to prevent any further tickets from being issued by the same person. We have before pointed out that there are two methods for putting an end to this nuisance of issuing tickets to parties for whom they are not intended, which, if carried out, would be a great boon to the hardworked dispensary doctor; viz., either to render liable for the medical attendance whoever gives the ticket, or to take from him the power of signing tickets for the future.

**DONATIONS, ETC.**—Mrs. Thompson has given £100 to found a bed in memory of her husband, the late Dr. Thompson, in the Cripples' Home, Bray. The Hospital for Incurables, Donnybrook, will receive a bequest of £700 from the late Mrs. O'Grady; and £100, being the second instalment out of property left by the late William Hogan for charitable purposes.

**WEST KENT MEDICO-CHIRURGICAL SOCIETY.**—The sixth meeting of the twenty-second session was held on Friday, March 1st, at the Royal Kent Dispensary, Greenwich Road; W. Johnson Smith, F.R.C.S., President, in the Chair. Dr. A. L. Galabin read a paper on Operative Measures for the Relief of Congenital Atresia Vaginae. The next meeting is to be held on Friday, April 5th, at the same place. Dr. J. C. Thorowgood will read a paper on the Use of Mercury in Certain Inflammations.

#### ARMY MEDICAL SERVICE.

WE are glad to be able to state that, in connection with the inquiry of the War Office Committee now sitting to examine into the causes of the present unpopularity of the Army Medical Department among the students of the medical schools, the Secretary of State for War has addressed a communication to the authorities of the medical schools of Great Britain and Ireland, asking why it is that candidates do not come forward in sufficient numbers for the army medical service; and requesting them to offer suggestions for the improvement of the service, which he expresses himself as anxious to effect. We cannot but applaud so judicious a step on the part of the Secretary of State for War, which indicates a conviction that the War Office must depart from its former policy of ignoring the views expressed by our Parliamentary Bills Committee on this subject, as set forth by its deputations, that a satisfactory settlement of this question cannot be attained without consultation with the heads of the medical schools, and the settlement of the terms of service in the army on a basis compatible with its efficiency, at the same time offering sufficient inducements to make the service popular with the younger members of the profession.

A meeting of the lecturers and teachers in the various schools was held in the King and Queen's College of Physicians of Ireland on Wednesday last; the President of the College, Dr. Gordon, in the chair. Dr. Edward Hamilton, who is widely known throughout the profession as taking a deep interest in the department, stated that the object of summoning the meeting was to consider the best means of replying with unanimity to the very straightforward and candid inquiry of the Minister for War. He considered that there were five main distinct causes which combined to produce the existing difficulty in obtaining candidates; and, although there might be many minor causes, he advised that the replies to Mr. Hardy's query should be confined to these specific heads. These were as follows.

1. The existence of the ten-years system.
2. The uncertainty of warrants; and the difficulty that frequently arose in their interpretation, owing to the ambiguous language in which they are couched.
3. The abolition of the regimental system.
4. Medical officers not being placed on the same footing with their brother "combatant" officers as regards sick and ordinary leave.
5. The want of a system of retirement at the rate of £1 *per diem* after twenty years' full-pay service.

The meeting unanimously approved of adopting the course suggested.

#### MEDICAL TEACHING IN THE UNIVERSITY OF OXFORD.

A MODERATE and carefully drawn memorial has been prepared this week, for submission to the Royal Commissioners on the University of Oxford, respecting the relations between the University and the medical profession. It is pointed out in this memorial that the contributions to the science of medicine, and the influence of the University on the profession, are at present practically insignificant; and this is attributed to the absence of any adequate organisation in the University for medical teaching, or the promotion of medical science. The belief is expressed that a more intimate connection of the University with the profession would give to the University wider interests, and stronger claims upon national sympathy; would improve the general culture of the profession, and help the progress of medical and biological science. It is pointed out that European universities, with scarcely an exception, recognise the preparation of young men for the medical profession and advancement of medical science, as among the most important of academical functions; and that such obstacles as have been alleged to stand in the way of medical education at Oxford appear to be surmounted in other universities similarly situated. On these grounds, the present state of things at Oxford is regretted; and the Commissioners are asked to consider how far, and in what way, the imperfection may be remedied, so far as it begins with an avoidable cause. This memorial has been, in the course of the last day or two, signed by many eminent professors and teachers of medicine in London, as well as by members of the University of Oxford, generally interested in its welfare and in the perfection of its academical arrangements. The adhesion of those members of the medical profession who feel interested in the subject may be communicated to Dr. Frank Payne, Wimpole Street, one of the graduates of the University who are interesting themselves in the effort to improve the relations between the University and medical teaching, and the promotion of medical science.

## HARVEY TERCENTENARY MEMORIAL FUND.

THE following letter has been sent during the past week to the various British Universities, Medical Corporations, Medical and other learned Societies, and to the Committee of Council and the various Branches of the British Medical Association.

"It is an approved custom in civilised countries to recognise and mark distinguished services to mankind by the erection of statues or other public monuments. There is in England no such national recognition of the services of Harvey, the discoverer of the circulation of the blood, who, by his labours resulting in that discovery, laid the foundation for all progress in physiology. The third centenary of his birth is now approaching, and it is felt that this will be a proper opportunity for erecting a statue of Harvey at Folkestone, where he was born. A movement to effect this object has been initiated at a public meeting held at Folkestone, and the project has been warmly espoused in London and elsewhere.

"Under these circumstances, we, the members of the London Executive Committee of the Memorial Fund, feel that we may appeal with every confidence of support to all classes of the community, especially to the Universities, to the Medical Corporations and Schools, and to the Medical and other learned Societies of the United Kingdom. We therefore ask that you will kindly bring this matter under the notice of (the Committee of Council of the British Medical Association), and seek to obtain for this project the kind co-operation and assistance of your Council in providing the necessary funds for the erection of the proposed statue.—We have the honour to be, sir, your obedient servants.

"George Burrows, M.D., Prescott Hewett, *Honorary Treasurers*.—William W. Gull, M.D.; James Paget; Richard Quain, M.D.; G. Owen Rees, M.D.; John Simon; Ed. H. Lushington; D. H. Stone.—George Eastes, M.B., 69, Connaught Street, Hyde Park Square, London, W.; W. G. S. Harrison, B.A., Town Clerk, Folkestone, *Honorary Secretaries*."

A considerable addition to the fund has been made during the week. A special list of subscribers will be printed in the *Times* on Monday next, which is the three hundredth anniversary of the birth of Harvey.

At the West Surrey District meeting of the South Eastern Branch held at Guildford last week, the sum of seven guineas was subscribed by the members to the Memorial Fund. At the East Kent District meeting held the same day at Dover, it was resolved that the Council of the South-Eastern Branch should be requested to accede to the request of the Executive Committee of the Fund by a subscription from the Branch. On Wednesday last, the Metropolitan Counties Branch voted ten guineas to the Fund, and subscriptions in aid of the object were requested from the members. If the various Branches to which the letter of the Executive Committee has been forwarded respond in the same liberal spirit, the result cannot fail to be a very handsome addition to the Memorial Fund. At the same time, we would urge the individual members of the profession on this special occasion to send donations and prevail upon their friends to do the same, in order that the subscription-list may be shortly closed, and the necessary instructions given for the completion of the statue.

## HOSPITAL AND DISPENSARY MANAGEMENT.

## ROYAL SURREY COUNTY HOSPITAL, GUILDFORD.

A CORRESPONDENT of the *Charity Organisation Reporter* of March 21st says:—"At the annual meeting held on February 28th, the report was read, stating that the out-patients had increased to three thousand and fifty, and that this large number unduly taxed both the funds of the hospital and the powers of its medical staff. The hospital is at present working at a loss of about £250 *per annum*, and the expense of the out-patient department is about £372. With a view to meet this expense, and also ease the medical staff, the Committee propose to the governors to charge one shilling on each letter brought by an applicant. (These letters are available for one month, and, if the patient require visiting at his own home, he has to produce two letters.) There was some discussion as to whether this proposal was as good as reducing the governors' letters by one-half; but, being strongly urged by the Committee, the proposal was carried by twenty-one to nine. There is unfortunately no provident dispensary in the neighbourhood; but, as the want of one was alluded to in the course of the discussion, there seems a chance of one being originated. It would seem that the above vote will require confirmation by the Court of Governors six weeks hence."

## REPORTS OF SOCIETIES.

## PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MARCH 19TH, 1878.

CHARLES MURCHISON, M.D., D.C.L., F.R.S., President, in the Chair.

## DISEASES OF THE LYMPHATIC SYSTEM.

THE discussion on the diseases of the lymphatic system was illustrated by a large series of microscopic sections by Drs. Whipple, Gowers, Greenfield, Mr. Nunn, and others. The PRESIDENT suggested that the discussion should be deferred until the different speakers and exhibitors had been heard: a suggestion adopted forthwith.

*Leukæmic Viscera*.—Dr. WILKS commenced by referring to the original preparations of Dr. Hodgkin, which were exhibited. He said that Dr. Hodgkin wrote the first distinct paper on the disease, though so marked a disease must have been noted, more or less, from all time. This paper was published in the *Medico-Chirurgical Transactions* for 1832, vol. xvii. In it the disease was clearly defined for all time. It was illustrated by six specimens, of which five were those of viscera, and of these four were exhibited. The first case was a boy aged 9, who died of dropsy and peritonitis, in whom the mesenteric glands were like pigeon's eggs. There were also tubercles in different viscera. The second case was a boy aged 10, who had an enlarged spleen, and died of general anasarca. The glands of the neck were enlarged without any softening. Other glands were enlarged, the liver was large, and the spleen full of deposit. In the third case, the glands of the neck and groin were enlarged, firm, and white, from morbid hypertrophy of the gland structures. The spleen was enlarged, with small white opaque spots in it. The fourth case was that of a man aged 50, in whom the glands of the neck, groin, and axilla were enlarged, as were those of the mediastinum. Other glands were large, and the viscera contained tubercles. Dr. Hodgkin said that all were agreed that the enlargement of the absorbent glands in this disease was a primary affection of these bodies, and not a secondary change. It consisted of a general hypertrophy of all the tissues of the glands, without any tendency towards suppuration or the formation of pus. The spleen was usually affected, resembling miliary tubercle. The disease had not been clearly defined before, but had been confounded with malignant disease. It was not a form of cerebriiform cancer, as Sir Robert Carswell had thought. Dr. Bright observed the changes in the spleen, and thought it a form of malignant disease, but he distinguished it from cancer and from scrofulous disease. The white matter in the spleen closely resembled suet. In 1853, Dr. Markham described a case of Hodgkin's disease before the Society; and Dr. Bristowe thought it was neither malignant nor scrofulous. The disease, however, had malignant characteristics, as these enlarging glands had been known to eat their way into the trachea and the bronchi. In one case which he knew, a man broke his leg in going upstairs, and at last it was found that his bones were destroyed by infiltration into the interosseous spaces. Had the disease any relation with tubercle, or with lardaceous disease? In his own first communication on this disease, he called his paper "Lymphatic Diseases with Allied Diseases". Was the blood affected? Virchow's definition was then given. In the splenic form, the cells were large; in the lymphatic form, the cells were small. In lympho-sarcoma, there was no increase in the number of white blood-corpuscles, while in Hodgkin's disease leukaemia was undoubtedly present. He should also like to hear of its relations to bone-marrow, and, still more, to suppuration. A case occurred at University College Hospital, where leukaemia was present while an abscess formed, and disappeared on its healing up. The term leukaemia was often loosely used, and applied to conditions where white blood-corpuscles were seen in excess of the normal number.

*Lymphadenoma and Leucocythæmia*.—Dr. GREENFIELD exhibited specimens, drawings, and microscopic sections from these maladies. The first case was one of lymphadenoma. It occurred in a man twenty-six years of age. He had first an attack of eczema, and then a lump formed in his neck; it grew, and then diminished in size several times, till the glands became involved. There was weakness, with loss of flesh, and the belly swelled. On *post mortem* examination, it was found that the glands of the neck, axilla, and groin were swollen, while the spleen weighed fifty-one ounces. The man died from the pressure of enlarged glands upon the recurrent laryngeal nerve. Many other glands were involved. The second case was that of a boy aged 12, who had a swelling on the left side of the neck, then under the axilla, and finally in the groins. There was a high temperature, extending to 103, 104, and 105 deg. Fahr. He died ulti-

mately of asthenia. The cervical glands were found hard, as were those of the axilla, and there was nodular infiltration of the chest-walls, which extended down to the nipple. The glands on the right side were also enlarged, but not to the same extent. The thymus was enlarged and infiltrated. The spleen was large, and the liver had nodules in it; there was infiltration along Glisson's capsule. In the third case, of a man, the glands on the left side of the neck grew rapidly; then those of the right side; then those of the groins. The spleen was large. In the fourth case, also a man, there was a mass of enlarged glands in the left groin as big as a cocoa-nut. Then the glands along the iliac vessels and aorta enlarged. There were two masses close to the sternum, consisting of enlarged mediastinal glands. There was irregular infiltration of the left pleura, just as if candle-fat had trickled over it. He died of exhaustion. The spleen weighed twenty-five ounces, but was simply hypertrophied. The fifth case was that of a man aged 33, who had a lump under his left ear, which extended into the posterior triangle. He had abdominal pain and ascites, and became much emaciated. At the necropsy, the cervical glands were found not to be confluent; and there was no enlargement of the glands on the right side. The peritoneum was affected, resembling tubercular peritonitis. The spleen was unaffected. On microscopic examination of the glands in eight cases, it was found that the chief change was the fusion together of the glands and gland elements by a growth of fibrous tissue, causing them to be white and hard. In some, the growth was soft and pinkish; in others, the material was pigmented; in a few, it was caseated. The growth was an indurative overgrowth of the retiform tissue, which invaded the rest of the gland structures, until they were all lost in the new growth. Large multinucleated cells were found adhering to the reticulum. As to the spleen in eight cases: in one it was unaffected, in two it was enlarged by increase of the splenic pulp, while in the other five there was the typical growth. First, there were bands of fibrous tissue resembling cross sections, which grew chiefly around the arterioles. Then, neelike masses developed, which destroyed the splenic pulp by rapid induration and growth of giant-cells. The changes in the liver were much the same, the growth being chiefly in the walls of the portal canals; there was rapid caseation in some instances. This growth caught tracts of lobules which underwent fatty degeneration. The capillary network remained good, though the liver-cells underwent fatty degeneration. In the capillaries near the new growth there were often masses of protoplasm growing from their epithelioid lining, and possibly taking part in the new growth. He showed specimens from a case of leucocythæmia, in which there were numerous hemorrhages. The child died, and hemorrhages were found in the kidneys, the heart-walls, and elsewhere. In one case of lymphadenoma, the white blood-corpuscles were increased in number. In others, there was anemia only. In two cases, microcytes, small red blood-corpuscles, were found when the temperature was high. Was this high temperature due to inflammatory action, inflammation bearing a different meaning now from what it did in Dr. Hodgkin's time? Was there some inflammation of the glands with pyrexia in the latter stage, the cachectic stage of Trousseau? The pyrexia was intermittent. In leucocythæmia, the so-called growths really consisted entirely of white blood-corpuscles.

*Leucocythæmia and Lymphadenoma.*—Dr. GOWERS showed two cases of lymphadenoma. One was a man with a tumour in the neck, and enlargement of the other cervical glands and of the glands in the axilla. There was slight anemia, with excess of white blood-corpuscles, forty in each field. The other was a girl who had enlarged cervical glands, and of the glands of one axilla several years ago. The latter were removed; and since then, there had been a very slow growth. Charts of the blood-corpuscles were shown. Sections of the spleen in lymphadenoma were shown. Pigment was accumulated on the margins of the growths, but not within them. Many growths were obviously around arteries, and probably all were so: hence it was probable that, as Dr. Hodgkin had suspected, the growth originated in the Malpighian follicles and periarterial tissue, and not in the splenic pulp. This certainly confirmed Malpighi's idea, that the follicles were part of the lymphatic system. As to changes in the spleen, Dr. Gowers said, of ninety-seven cases of Hodgkin's disease, in fifty-seven (60 per cent.) there were splenic growths; in 20 per cent. the spleen was normal; and in the other 20 per cent. there was simple hypertrophy. What was the nature of the change causing the apparent hypertrophy of the pulp in splenic leucocythæmia? There was evidently a growth in the position of the pulp; but it was recently said that this was really a diffuse invading growth from the Malpighian follicles. In cases intermediate between lymphadenoma and leucocythæmia, there was a follicular growth; but, apart from this, a great increase in the pulp itself could be recognised, causing the enlargement of the organ. The Malpighian follicles in such cases, as in one shown, might suffer lardaceous degeneration alone; hence it was probable that the pulp itself was the

real seat of the change in leucocythæmia. Other sections illustrated the changes in the glands; and especial attention was called to the great increase of fibrous tissue around the arteries. In proportion as the glands enlarged, the intercellular stroma increased, causing induration. Was the secondary glandular enlargement in splenic leucocythæmia a growth or the accumulation in them of white corpuscles? If the latter, its occurrence should be proportioned to the degree and duration of the excess of white corpuscles in the blood; but no such relation could be traced. In most cases of extreme blood-change, the glands were not enlarged; hence Virchow's view that the change was a growth, was probably correct. Sections of growths in the organs were also shown. What was the relation between the lymphatic diseases? The French writers classed them all as one disease; certainly there were intermediate forms between the well-marked varieties. They were a continuous series; and yet distinctions were acknowledged betwixt the broader forms. To ascertain how far the obvious distinctions were borne out by other details, Dr. Gowers had compared one hundred and fifty-four cases of primarily splenic leucocythæmia with one hundred cases of primary gland-disease. Two-thirds of the cases of splenic disease and three-quarters of the cases of gland-disease occurred in males. As to the age at which death occurred, leucocythæmia differed from lymphatic gland-disease. Thus, in leucocythæmia, the death-rate, rising from four per cent. under ten years, culminated betwixt the thirtieth and fortieth years, during which thirty per cent. of the deaths occurred; while the line of death-rate in primary disease of the lymphatic glands reached a high point betwixt the twentieth and thirtieth years, recedes during the next decade, and rose again betwixt the fiftieth and sixtieth years, falling low during the decade when the other culminated. The glands most commonly affected in leucocythæmia (the mesenteric) were those least affected in lymphadenoma. As to the relations to intermittent fever, it was found that there was little connection betwixt lymphadenoma and aguish districts, while a large proportion (twenty per cent.) of the cases of leucocythæmia had either lived in malarial districts or had had ague. As to the nomenclature, "Hodgkin's disease" was a neutral term, but was not in use on the Continent; and here even, lymphadenoma was the term which seemed most likely to survive, but was applied to the growth. Would not lymphadenosis form a good term for the general disease?—In answer to a question put by the PRESIDENT about the proportion of white blood-corpuscles in the blood of the two patients exhibited, Dr. GOWERS said they were increased in one case, but not in the other.

The discussion was adjourned.

## HARVEIAN SOCIETY OF LONDON.

THURSDAY, MARCH 7TH, 1878.

W. B. OWEN, Esq., Vice-President, in the Chair.

*Use of Thymol.*—Dr. A. WILTSHIRE made a communication on the use of thymol. He said it made a good ointment mixed with vaseline; but the quantity must be small, otherwise it was very irritating. It was a much more powerful germicide than carbolic acid. It was also deodorant and disinfectant. It could also be used as a lotion dissolved in alcohol and water.—Mr. OWEN, Drs. STEWART, FOTHERGILL, GIBBON, EDIS, MALCOLM, MORRIS, and GRIFFITH took part in the discussion which followed; after which Dr. WILTSHIRE replied.

*Treatment of Syphilitic Disease of the Brain and Nervous System.*—Dr. T. S. DOWSE read a paper on this subject. It did not include congenital syphilitic affections. Acquired syphilitic diseases of the nervous system yielded readily to appropriate treatment. The actual injury done to the nerve-structures could never be repaired. He related a case where the moral character was much affected by such disease, and restored again as the patient recovered generally. The treatment should be early and active. At a certain stage, both mercury and iodide of potassium were useless, indeed harmful. It was when the urine was albuminous and there was general depression. Here good food and stimulants were indicated. Alcohol was very useful at such times. Each case must be treated by itself for success. He thought mercury the remedy *par excellence* for syphilis, and dissented from the present view that it was only adapted for the early stages; while iodide of potassium was the remedy for the later changes. Some patients could only tolerate one or other of these remedial agents, and the treatment must be conducted accordingly. Baths containing iodide of potassium were often of service when other methods of administering this drug had failed. In acute congestive syphilitic disease of the brain, it was necessary to lower the vascular activity. For this end, chloral was serviceable. Cooling spirit lotions to the head were useful. The patient, however, should be fed well. If an epileptic seizure occurred,

it was well to give purgatives. When depression set in, then active stimulant treatment becomes necessary. He strongly advocated the resort to galvanism in comatose conditions. The general management of these diseases consisted of rest and quiet. Headache should always receive immediate attention. For neuralgia of the fifth nerve, hot solutions of chloral were most useful.—Mr. OWEN, Mr. EDMOND OWEN, Drs. GIBBON, GRIFFITH, and WILTSHIRE spoke on the paper; after which Dr. DOWSE replied, and the meeting adjourned.

#### GLASGOW CLINICAL AND PATHOLOGICAL SOCIETY.

TUESDAY, MARCH 12TH, 1878.

JOSEPH COATS, M.D., President, in the Chair.

**Tumour of the Ankle.**—Dr. JAMES DUNLOP showed a tumour of the size of a hen's egg, which he had removed from the outer aspect of the ankle of a woman aged 45. The tumour had grown for two years, and was closely adherent to the periosteum, though not attached to the bone. Dr. Foulis had examined it, and found it to be composed of small spindle-shaped cells.

**Urethral Calculus weighing Six Drachms.**—Dr. DUNLOP showed a calculus which he had removed from the prostatic portion of the urethra by lateral lithotomy (with the rectangular staff). The patient, a lad aged 19, stated that twenty months before admission he began to suffer from the symptoms of stone in the bladder; and that, after eight months' duration, these symptoms were suddenly complicated by obstruction to the flow of the urine, following prolonged exercise in dancing at a country gathering. Thereafter the urine merely dribbled away, and symptoms of distension of the bladder were present. Occasionally, the urine was bloody. On admission, an attempt was made to pass a sound, but this was found to be impossible, even under chloroform; a hard body was felt, both with the sound and with the finger *in recto*, lying in the prostatic and membranous parts of the urethra. The urine was fetid, ammoniacal, purulent, and bloody. At the operation (on February 6th, 1878), the stone was easily removed, and the extraction was followed by the escape of a large quantity of urine. There was almost no hæmorrhage at the time; but, on February 14th, a free flow of blood took place from the wound, and this recurred on February 16th and February 19th. No bleeding point could be seen; and Dr. Dunlop, therefore, tied in a full-sized catheter, and plugged the wound with strips of lint soaked in perchloride solution. The patient made a good recovery. The catheter was removed on the 8th day, no irritation having followed from its use, and the wound was now quite healed. The calculus was composed of a nucleus of uric acid, round which was a layer of oxalate, the outermost coating being of phosphates.—Dr. GEORGE BUCHANAN said the structure of the calculus showed that it had been formed in the bladder, and had then escaped into the urethra. The hæmorrhage had probably come from the enlarged prostatic veins. He had never seen secondary arterial hæmorrhage after lithotomy. It was remarkable to what a size calculi might grow in the urethra, without causing obstruction to the flow of urine. They became encapsuled in a sort of false pouch by the dilatation of the urethra.

**Calculus encysted near the Root of the Penis.**—Dr. KNOX showed two calculi closely faceted upon each other, total weight three drachms and a quarter, removed by him from near the root of the penis of a man aged 22. At the age of 2, the patient had received a blow over the seat of the calculus, and for many years there had been obscure symptoms of vesical disorder. When seen by Dr. Knox, there was a hard lump at the right side close to the corpus spongiosum, and in this lump a harsh crepitation could be made out. Nothing could be made out with the sound; the urine was alkaline and phosphatic. An incision was made over the lump, and the stone extracted; the corpus spongiosum was found to be involved in the cyst-wall, and there was a free flow of blood. Dr. Knox learned that, at the age of 5, the patient had passed one or two small calculi *per urethram*.—Dr. H. C. CAMERON had seen three cases of prostatic calculus. In one case now under his care, he had pushed a calculus into the bladder and there crushed it; the debris were phosphatic. In the second case, three hundred calculi were removed by lithotomy; and in third case fifty calculi had been taken out. In all the cases which he had seen, the calculi were multiple and faceted, and composed of phosphates.

**Early Ocum.**—Dr. JAMES DUNLOP showed an ovum expelled at the third week; and he alluded to the opinion expressed by a German writer, that, when expelled under diseased conditions, the ovum was usually entire, whereas ova expelled in circumstances of criminal intention were usually broken up.

**Rotary Lateral Curvature of Spine.**—Dr. DAVID FOULIS showed five spines with rotary lateral curvature; and also Judson's apparatus for illustrating the subject. Dr. Foulis stated that, having had his atten-

tion directed to the subject, he had carefully examined all the spines in the *post mortem* room, and he had been surprised to find that, of forty-five adults, the spine was more or less twisted in thirty cases, while in the remaining fifteen the spine was perfectly straight. The method he employed was, in the first place, to clean the front of the spine from all loose tissue, and then, the body being placed quite straight, a thin wooden rod was employed to gauge the straightness of the spinal column. In the slighter cases, the twist was confined to the bodies of the vertebrae; in the more advanced cases, the spinous processes were also displaced, always to the same side as the bodies. The deviation was not limited to any one part of the spine, nor to either side; there were always slight compensatory curves present. The facts seemed to him to confirm Mr. Adams's theory, that faulty posture while at work was the starting-point of many cases of spinal curvature.—Dr. MACEWEN said that on one occasion he examined the spines of fifteen patients in one of his wards, and detected a trifling deviation of the spinous processes in twelve cases.—Dr. CAMERON thought that in the younger patients the curvature (usually to the right side) was probably due to faulty habits in sitting at study, etc.; while in later life the irregular slight curves exhibited by Dr. Foulis were probably the result of the nature of the occupation.

**Case of Croup.**—Dr. EBEN DUNCAN showed the larynx and exudation from a case of croup. He had examined the mucous membrane and the exudation for micrococci, and failed to find any; but, after soaking the cast (of exudation) in water, he found some micrococci in the fluid. He thought micrococci were more of a *post mortem* than of a *pre mortem* nature, and that the micrococci found in the mucous membrane of the throat in diphtheria might have spread into it from the exudation. In many cases, the exudation was decomposing during life, and in these there might be micrococci developed before death. He thought the term diphtheria rather vague. There was no one sign pathognomonic of it.—Dr. JAMES B. RUSSELL said that he had been much struck in examining large masses of statistics from all parts of the country, to see how the disease set down as croup ranked itself with the lung-diseases, while the disease called diphtheria was evidently akin rather to the typhoid and other fevers. He was aware that, in individual cases, there was often difficulty in distinguishing between the two diseases; but, taking the great mass of figures, he was driven to conclude that there must be some difference.

**Sarcoma of the Eye.**—Dr. THOMAS REID showed an eyeball removed by him from a man aged 33. When admitted to the Eye Infirmary, the patient complained of defective vision in the right eye; the pupil was normal, and reacted to light; one or two dilated veins were seen on the sclerotic at the side of the eyeball; the outer half of the field of vision was extinct, and the remainder defective. With the ophthalmoscope, an opaque crescentic body was seen behind the lens; the retina near it was detached. After enucleation, sections were made, and a brownish friable tumour was found enveloped in the detached retina a little behind the ciliary body. It was of the size of a filbert. The microscopic structure was that of alveolar sarcoma. Dr. Reid said that he attached great weight to the presence of dilated veins on the sclerotic over the tumour as diagnostic of sarcoma. He thought enucleation should be performed early in such cases.

#### GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MARCH 1ST, 1878.

EBEN WATSON, M.D., President, in the Chair.

**Midwifery Forceps.**—Dr. J. T. WHITTAKER showed a form of revolving midwifery forceps, the principle of which consisted in the application of both blades at once, this being effected by means of a ball and socket joint in the middle of the instrument, which enabled the one blade to move round the other. He also showed a styler for rupturing the membranes.—Dr. W. L. REID made some remarks on the long forceps, and exhibited a new form of that instrument with the intention of supplying four deficiencies which exist, he alleged, in the present forms: 1. By means of a perineal curve to a limit of traction exactly in the axis of the pelvic inlet; 2. By means of a swivel-joint at the handle to permit of the head accommodating itself to any kind of abnormality in the cavity; 3. By means of antero-posterior blades (to be applied obliquely, however) to have the handles an exact index to the position of the blades and in the same axis; and 4. By means of a pelvic nerve in the shanks instead of the blades to admit of its being used to rotate the head from the occipito-posterior to the occipito-anterior positions.—Dr. DAVID CHRISTIE of Donegal also showed a new form of long forceps, in which he applied traction by means of hooks, and regulated pressure in one of the handles.

**Arrest of Uterine Hæmorrhage.**—Dr. D. CHRISTIE explained an in-

genious and simple method of arresting uterine hæmorrhage. This consisted of an India-rubber bag, which was smeared with glycerine and introduced into the uterus; water was pumped into it, and by its distension and pressure the hæmorrhage ceased. A tube connected with the bag had its distal extremity raised two feet, and when an uterine contraction took place the water which was expelled through the tube was received into a tumbler or other small vessel. In the event of the contraction not being maintained, the water ran back by syphon-action into the bag, and the bleeding was controlled. Dr. Christie had used this successfully in *post partum* hæmorrhage and placenta prævia.—A discussion followed, in which Drs. WALLACE ANDERSON, HUGH THOMSON, STIRTON, HUGH MILLAR, and MURDOCK CAMERON took part.—It was decided to refer the three specimens of forceps to a Committee, who were requested to report upon them.

#### OBSTETRICAL SOCIETY OF DUBLIN.

SATURDAY, MARCH 9TH, 1878.

THOMAS DARBY, F.R.C.S.I., President, in the Chair.

*Milk-Fever.*—Dr. MACAN read a paper on this subject, in which he gave an exhaustive *résumé* of the theories held regarding the etiology of milk-fever from the time of Willis, who attributed it to the accumulation in the blood of easily fermentable menstrual particles, which had failed to escape as milk from the breast, or as lochia from the uterus. The term "milk-fever" was, he said, of great antiquity. But, in these days of critical investigation and general scepticism, the propriety of the term, nay even the existence of any such disease, had been called in question. His conclusions on the subject were the result of thermometric observation of 423 pregnant women in the Rotunda Hospital. In 114 of these, the rise in temperature during the whole period of observation never exceeded 1 deg. Fahr. And, if Wunderlich's fever-limit of 100.4 deg. Fahr. be accepted, there were 196 cases in which the temperature never rose to fever-height. In 32 cases, the only cause for a rise in temperature was a painful condition of the breasts. In many of these, the fever lasted over twenty-four hours, the longest duration being five days. The temperature was often greatly out of proportion to the pulse: temperature 104.4 deg. Fahr., with pulse 108; or temperature 103.5 deg. Fahr., with pulse 92, as occurred in two of Dr. Macan's cases. In septic infection, on the other hand, the pulse was too quick for the temperature. This difference was important from a diagnostic point of view. The conclusions which he drew from his statistics may thus be briefly stated. 1. No rise in temperature necessarily accompanied the first secretion of milk. 2. Pain and distension of the breasts might cause fever, but it was different from the so-called milk-fever; the latter seldom lasted twenty-four hours, whilst the former, coming on some days sooner, often did. 3. In the fever due to distension of the breasts, the pulse was sometimes slower than the temperature would lead us to expect. 4. In cases of fever, the mere presence of full breasts was not sufficient justification for at once concluding that no serious puerperal affection was present.—Dr. DENHAM asked if this fever was more frequent in primipare than in multipare. He thought the fever was due to the constitutional disturbance occasioned by the unwanted physiological processes going on in the system, rather than to the swelling of the breasts. Frequently the fever preceded, not followed, the secretion of milk. He thought it of importance to distinguish cases of fever with filling breasts from those in which the rigor came on with diminished lochia and flaccid breasts. The former were seldom of importance, whilst the latter should always be regarded as serious.—Dr. KENNEDY thought difference in temperament an important factor in the production of this fever, in addition to which, civilised habits might make a natural process of secretion be attended by fever. The same varieties, he said, were noticed in the natural processes of menstruation; some women were always feverish at such periods.—Dr. MACSWINEY alluded to an article by a New York physician, in which he ascribed what is called "milk-fever" to a mistaken mode of treating the parturient woman. The fever, he said, was one of irritation, and existed in direct proportion to the degree of starvation.—The PRESIDENT had seen breasts overflowing with milk before parturition took place; and recalled one case of an unmarried girl who suffered from symptoms similar to those of milk-fever, which ended in abscess of the breast.—Dr. MACAN, in reply, said the real question at issue was the cause of the fever. There could be no question as to its occurrence, but only as to the explanation of its cause. Numerous circumstances in the puerperal state might excite a fever similar to the so-called milk-fever, viz., surgical fever following the trauma of labour. Cracked nipples also might cause a temperature of 105 deg. Fahr. The President mentioned that he had seen a case of abscess of the breast in a virgin give rise to all the symptoms of milk fever. When symptoms of inflammation of the

breast, such as pain on pressure and redness of the integuments, were found in women after delivery, accompanied by fever, why should we not conclude that the fever is due to inflammation of the parenchyma of the gland?

#### SURGICAL SOCIETY OF IRELAND.

FRIDAY, FEBRUARY 15TH, 1878.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

*Amputation of Thigh for Ununited Fracture.*—Dr. WHEELER exhibited the leg and thigh of a man, which he had amputated by Mr. Teale's method, the rectangular flap operation. In a railway accident near Wigan in 1874, the patient received a simple oblique fracture about the middle third of the left thigh, which did not unite in consequence, he says, of a racking cough from which he was suffering at the time. To relieve this, his uvula was snipped off, without, however, affording any relief. Subsequently, a variety of methods were adopted to effect the union of the fragments. Twice they were pegged; once resected. For a considerable time, he wore a starched bandage, and was able to go about. He also described being beaten with a spoon over the seat of fracture, for the purpose, no doubt, of setting up a more healthy inflammation. When admitted into the City of Dublin Hospital, the lower fragment overlapped the upper by about five inches; the limb was, therefore, shorter, though as well nourished as the other. The knee was ankylosed. There was no pain in the limb, and the freest possible motion could be produced at the seat of fracture, it being quite easy to turn the fragments at right angles to each other. Over the upper fragment, he retained voluntary power, and could with it bulge up the skin of the thigh. He would not allow any means of saving the limb to be tried, unless Dr. Wheeler could promise him a movable knee-joint as the result. This being impossible, he insisted on having it removed, which was done on Tuesday last, as above stated. On examining the specimen, it was evident that a second fracture had occurred lower down in the thigh-bone, which had united. There was a considerable layer of muscle between the fragments, and round their extremities an adventitious membrane had been formed. The patient was doing well since the operation.

*Minute Aneurism of the Aorta.*—Dr. MOSS exhibited a very minute aneurism, which he removed from the body of a man of H.M.S. *Tophaz*. Whilst lifting a cask, the man felt something give way, and died in a minute and a half. The *post mortem* examination showed a small aneurism about the size of a pea to exist at the left side of the aorta, half an inch behind and to the left side of the right coronary artery. The opening was only of the size of a pin's head. Dr. Moss thought the case interesting from the small size of the aneurism, and the rapidity with which it proved fatal. The specimen was preserved in thymol, which he recommended as the best antiseptic fluid.

*Multiple Polypi in Uterus.*—Dr. KIDD showed six polypi which he had removed from the uterus of a girl aged 25. The patient's sister was also under his care, from whom he had removed twenty-nine polypi in four operations, performed at intervals of a few months. After the removal of the polypi, the interior of the uterus was swabbed out with fuming nitric acid. The cases were interesting, he thought, from the fact that most writers state that uterine polypi occur in almost all cases singly, and also from the apparent family predisposition to polypi.

*Farre's Tubera Circumscripita of the Liver, and Sections under the Microscope.*—Mr. RICHARDSON read a paper on this subject; and, after briefly mentioning Farre's explanation of the cupping of the tubers, drew the attention of the Society to some microscopic sections of the tubers made through their centres at right angles to the surface, exhibiting a cordlike band of fibrous tissue, which he thought was mainly instrumental in producing the central depression, though he did not deny the part played by the general contraction and the diminution in the amount of the cancer-juice. This band he compared to the cord tying down the button on a chair.

*Excision of the Hip.*—Dr. BARTON read the notes of a case of excision of the hip in a boy aged 4½, who had suffered from old-standing hip-disease, which suppurated. On opening the abscess, a quantity of offensive smelling gas and pus bubbled out. Dr. Barton excised the head of the bone, and gouged away a quantity of carious matter. The acetabulum was covered with granulations; no special antiseptics were used, but the wound was kept freely open, and frequently washed out with a weak solution of chloride of zinc. The limb was now one inch and three-eighths shorter than the other, but the motion in both foot and knee were perfect, and the thigh could be flexed on the abdomen to an angle of 60 deg. The boy, who before the operation was nearly wasted to a skeleton and dying from exhaustion, was now plump and strong, and able to walk with a crutch. Dr. Barton then showed the Society a boy on

whom he had operated four years ago under very similar circumstances. He was able to walk without crutch or assistance of any kind, with only a slight halt, supporting the whole weight of his body on the affected limb, which was two inches short, in consequence of the section having been made below the great trochanter. The case was remarkable as being the first successful excision of the hip in Ireland.—Some discussion took place as to the stage of the disease at which the operation was most advantageously performed. Dr. Barton considered it best suited to the third stage, and thought it unjustifiable until all other methods had failed and the patient's life endangered from the constitutional disturbances.—Several of the members related similar cases, the results of which, however, were not all so satisfactory as those of Dr. Barton.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, FEBRUARY 16TH, 1878.

EDWARD HAMILTON, M.D., President, in the Chair.

*Disease of Knee-joint.*—Dr. T. EVELYN LITTLE, on behalf of Dr. E. C. THOMPSON, Surgeon to the County Tyrone Infirmary, presented a specimen of extensive disease of the upper end of the tibia and neighbouring parts. The patient was a girl aged 3, whose right knee was "strained" thirteen months ago. The joint swelled, became painful, and matter formed. The limb underwent contraction, the leg being bent at right angles to the thigh. Startings of the limb occurred, the inguinal glands became enlarged, and an abscess discharged through a sinus below the tuberosity of the tibia. Resection being inadmissible, the limb was amputated by the double flap operation at the lower third of the thigh. As regards the soft parts in the leg, sinuses were found leading to diseased bone and to the knee-joint. The knee-joint itself contained pus; its capsule was thickened; the cartilages were in places ulcerated and absorbed; the floor of the joint was perforated through both articulating facets of the tibia; and vascular synovial fringes lay free in the joint. As regards the bones, the patella and femur were comparatively healthy (as were their cartilages also); but there was extensive disease of the upper cancellated tissue of the tibia, in which, indeed, a small sequestrum lay. Dr. Little considered that the focus of the disease was originally below the joint, *i.e.*, on the tibia, basing this opinion on—1. The site of the abscesses; 2. The relatively intact condition of the femur; and 3. The rapidity of the formation of abscess and sinuses.—Dr. E. H. BENNETT, recalling the observations of Chassaignac, Cruveilhier, etc., looked upon the affection as primarily an osteo-myelitis in the head of the tibia.

*Peculiar Multiple Fracture of Femur.*—Dr. E. H. BENNETT showed a very deformed femur, fractures of which had occurred subsequently to disease of the knee-joint. In early life, the subject of the injuries suffered from destructive disease of the left knee, which invalidated him for many years. Firm osseous ankylosis of the joint resulted—the tibia, patella, and femur being welded together, with subluxation of the tibia backwards, and ankylosis of the patella to the outer femoral condyle. The man was intemperate and got falls, which caused fracture of the shaft of the femur on two occasions. In both fractures, there was inversion of the lower fragment. The patient died of malignant disease of the stomach, aged about 70.

#### THAMES VALLEY BRANCH.

MARCH 14TH, 1878.

W. PRICE JONES, M.D., President, in the Chair.

*Spinal Lesion in a Child.*—Mr. G. FARR WHITE related a case of spinal lesion occurring in a child three years of age, and supposed to be the result of getting wet. There was, in the first instance, general pyrexia, but no vomiting. Later on, the head was thrown back on the spine; there were muscular spasms, and both legs were drawn up on the abdomen; the right seemed especially weak. The case ended in permanent paralysis of the right leg. Mercurialunctions and purgatives seemed to do most good. Sedatives, such as chloral, chlorodyne, bromide of potassium, etc., were of little service; while galvanism and strychnia in the chronic stage yielded negative results.

*Laceration of the Scalp.*—Mr. FARR WHITE described a case of laceration of the scalp about the region of the left temporo-parietal bone, accompanied by paralysis of the right arm, pain in the neck, and spasms down the right side when the front or back of the right shoulder was touched. There was no fracture of the skull, nor bleeding from the nose or ears. The left pupil was slightly dilated, though sensitive to light. The tongue was protruded in the straight line. There was great shock; and consciousness, with vomiting, did not occur till four hours after the accident. There was paralysis of the bladder for six days after the accident. During sleep, there was very stertorous

breathing, and the respiration was excessively slow. There were no head-symptoms, and the nerves of special sense were unaffected.

*Paroxysmal Hematuria.*—Dr. FENN of Richmond communicated particulars of four cases of paroxysmal hematuria which had been under his care.—Case I. A woman, aged 49, was seen in her fifth attack, which existed eight weeks. The first attack occurred sixteen years before. The complications were tonsillitis and subacute rheumatism.—Case II. A woman, aged 22, had a fourth attack, the duration of which was two weeks. The first attack occurred three years before. The complications were muscular pains and debility.—Case III. A young man, aged 18, had a fifteenth attack, which lasted a day. The first attack took place four years before. Anemia and subacute rheumatism existed as complications.—Case IV. A boy, aged 14, had the first attack, the duration of which was six weeks; it was complicated with mitral disease and rheumatic enlargement and tenderness of the finger-joints. The urine possessed the usual characters as described by all observers. In colour, it was very dark and opaque; the quantity was in excess. There was a copious brown deposit, exhibiting under the microscope a few misshapen blood-corpuscles or none at all, granular matter (hematin?), uric acid, and oxalate of lime crystals in abundance.—The author suggested the following sequence of events in this pathological condition: 1. A rheumatic or neurosal diathesis; 2. Defective assimilation, and consequent formation of unstable blood-elements; 3. A paroxysmal or continued disturbance of the nerve-ganglia which regulate the functional activity of the blood-glands; 4. A consequent rapid retrograde metamorphosis and imperfect oxidation of the blood-elements, shown by 5. An excess of *débris* thrown off by the kidneys in the form of unaltered hematin-granules, uric acid, and oxalate of lime. The prognosis was uniformly favourable. The treatment was unsatisfactory. In the prolonged cases, all styptic and astringent remedies seemed to fail. The chief indication then left was to nourish the patient as well as possible, and insist upon rest and warmth at the commencement of the attack.

## ASSOCIATION INTELLIGENCE.

### THAMES VALLEY BRANCH: ORDINARY MEETING.

A MEETING of this Branch was held on March 14th, at the Griffin Hotel, Kingston: Dr. PRICE JONES in the Chair.

*Communications.*—The following communications were made.

1. The CHAIRMAN brought forward a case of Epithelioma of the Tonsil.
  2. Mr. G. FARR WHITE related a case of Spinal Lesion in a Child Three Years old.
  3. Mr. FARR WHITE described a case of Laceration of the Scalp.
  4. Dr. FENN described four cases of Paroxysmal Hematuria.
- Dinner.*—The members (nineteen in number) afterwards dined together.

### SOUTH-EASTERN BRANCH: WEST SURREY DISTRICT.

THE second ordinary meeting of the session 1877-8 was held at the Surrey County Hospital, Guildford, on Thursday, March 21st. Present: HENRY TAYLOR, Esq., in the chair, and sixteen members.

*Next Meeting.*—It was proposed and carried that the next meeting be held at Epsom on Thursday, October 24th, 1878.

*Ladies as Members of the Association.*—A resolution was proposed and carried unanimously: "That, in the opinion of this meeting, it is not considered advisable to admit women as members of the British Medical Association."

*The Secretary* was re-elected.

*Communications.*—1. Mr. HENRY SMITH (London) read a paper on Surgical Interference in Malignant Growths. He divided his paper into two parts: 1. With reference to the question generally, how far the surgeon is justified in removing, or attempting to remove, growths of an unmistakably malignant character; 2. As to the line of treatment which should be adopted when the surgeon interferes with cases of malignant disease involving the shaft of a long bone.—A discussion followed, in which Drs. Holman, D. J. Francis (late of Northampton), and Messrs. Knowsley Thornton, A. Napper, C. W. Childcott, C. J. Sells, and H. Smith took part.

2. Mr. T. M. BUTLER showed a specimen of Diseased Kidneys in a child ten years old.

3. Mr. HENRY TAYLOR showed a Tumour of the Pituitary Body taken from a child seven years old; the child was only ill four days before death; also a large solid Tumour of the Ovary.

*Dinner.*—Eighteen members and friends partook of a most excellent dinner at the White Lion Hotel; the usual loyal and other toasts being duly honoured.

## NOTICE OF EXTRAORDINARY GENERAL MEETING.

NOTICE is hereby given, that an EXTRAORDINARY GENERAL MEETING of Members of the Association will be held at the Queen's Hotel, Birmingham, on Tuesday, the 2nd day of April next, at Three o'clock in the afternoon:

1.—To consider Requisition, of which the following is a copy.

*To the President and Committee of the Council of the British Medical Association.*

Gentlemen,—We hereby request you to make arrangements for submitting the following resolutions to an early special general meeting of the British Medical Association.

"1. That this meeting is of opinion that the Reports of the Proceedings of the Committee of Council should be published in as complete and intelligible a form as is consistent with the conduct of business; and that in no case should important resolutions affecting the general interests of the Association be omitted."

"2. That this meeting desires to express its opinion that in the selection of a house for the Association, it is desirable that the Council, Committee, and consulting rooms should be separate from the printing and publishing offices."

II.—To consider the privileges of Lady-members.

By order of the Committee of Council,

FRANCIS FOWKE, *General Secretary.*

London, March 13th, 1878.

## COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, London, on Wednesday, the 17th day of April next, at Two o'clock in the afternoon.

FRANCIS FOWKE,

*General Secretary.*

36, Great Queen Street, London, W.C., March 25th, 1878.

## SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE next meeting of this Branch will be held at Carmarthen, on Thursday, April 4th.

Members desiring to read papers, etc., are requested to forward the titles to Dr. Sheen, Cardiff, before the 28th instant.

ANDREW DAVIES, M.D.

ALFRED SHEEN, M.D.

*Honorary Secretaries.*

March 11th, 1878.

## WEST SOMERSET BRANCH.

THE spring meeting of this Branch will be held at the Railway Hotel, Taunton, on Thursday, April 11th, at 5 P.M.

The following question has been settled by the Council as the one on which members should be invited to express their opinion at the said meeting after dinner:—"Is the Use of Water desirable in Dressing Wounds?"

The Secretary requests that early notice be sent to him of the title of any communication intended to be brought forward at the meeting.

W. M. KELLY, M.D., *Honorary Secretary.*

Taunton, March 16th, 1878.

## NORTH OF ENGLAND BRANCH.

THE spring meeting of this Branch will be held at Hexham, on Thursday, April 25th.

Gentlemen who are desirous of reading papers, introducing patients, exhibiting pathological specimens, or making other communications, are requested to signify their intention to the Secretary at their earliest convenience.

G. H. PHILIPSON, M.D., *Honorary Secretary.*

Newcastle-upon-Tyne, March 12th, 1878.

## SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT MEETING.

A MEETING was held at the Crystal Palace Hotel, Upper Norwood, on March 14th, 1878: R. M. MILLER, M.D., in the Chair. Twenty-seven members were present.

*Next Meeting.*—It was agreed that the next meeting should be held at Reigate, on October 10th, Dr. HOLMAN in the Chair.

*Secretary.*—Dr. GATTON was re-elected Secretary.

*Communications.*—1. The SECRETARY read a paper by Dr. Philpot on an Outbreak of Diarrhoea at Upper Norwood.

2. Mr. GOLDING-BIRD read a paper on the Treatment of Scrofulous Lymphatic Glands by the Electrolytic Caustic.

3. Dr. HOLMAN drew the attention of members to the important points to be decided by the General Meeting at Birmingham, on April 2nd.

4. Dr. POOLE read a paper on the Non-alcoholic Treatment of Post Partum Hæmorrhage.

5. Mr. SIDNEY TURNER read a Case of Abdominal Tumour.

6. Mr. SIDNEY TURNER read a Case of Opium Poisoning.

*Dinner.*—Fifteen members sat down to dinner.

## CORRESPONDENCE.

### THE JOINT COMMITTEE ON STATE MEDICINE.

SIR,—I observe that, in this week's JOURNAL, it is announced that I lately "resigned the membership" of the Joint Committee on State Medicine of the British Medical and Social Science Associations. It was the secretaryship which I have had the honour of holding since the Joint Committee was formed in 1867, which I resigned, as, owing to repeated illnesses during the last fourteen months, I had not been able to discharge the duties of the office with satisfaction either to the Committee or to myself. But, unless it is desired that I should retire from the Committee, I hope to be allowed to continue a member of it, and, with returning health, to make up, in some small measure, in that humbler capacity, for my many shortcomings as secretary. But, however this may be, I do hope that the threatened disaster of Messrs. Clode and Michael's retirement from the secretaryship may be averted, as I cannot but think it would be fatal to the usefulness of the Committee.—Yours, etc.,

A. F. STEWART.

March 27th, 1878.

## UNIVERSITY INTELLIGENCE.

### THE UNIVERSITIES OF SCOTLAND.

THE Royal Commission appointed early in 1876 to inquire into the management, constitution, etc., of the Scottish Universities have just issued their report. It is of very great length, extending to four volumes of blue books. At the end is a summary of the principal recommendations contained in the body of the report, and which are submitted for the consideration of the Crown in Council. From this summary, we extract the following notes from among the parts which especially interest the medical profession. It is proposed, in Section 18, that every candidate for a degree in medicine shall, before commencing his professional course, be required to pass a "first examination" in Latin, Mathematics, English, and either French or German. The two modern languages may be taken up in lieu of Greek. In Section 19, it states that no one shall be examined in Human Anatomy or Physiology, or any purely medical subject, until he has passed an examination in Natural Philosophy, Chemistry, Botany, Physiology, and Zoology, as constituting the second and third groups of the fifth or natural science department for the degree of M.A. Section 20 proposes that the final examination for the medical degree shall be confined to the practical subjects of medicine and surgery, both systematic and clinical, obstetrics, pathology, therapeutics, and medical jurisprudence (including hygiene); and that no candidate shall be admitted to examination in these subjects unless he has passed in the other subjects of the medical curriculum.

Section 21 proposes that the degree of M.B. shall not be conferred without a degree in surgery, the degree to be granted in surgery along with the Bachelorship of Medicine being that of Bachelor in Surgery (Ch.B.), which has been recognised as a registrable title by the Medical Practitioners' Act (1876); and that the examination fees to be paid by candidates for the double degree shall be twenty guineas, to be paid in instalments. Section 22 proposes that the degree of Master in Surgery (C.M.) shall be made attainable separately at a future time under similar conditions to those which now apply to the degree of Doctor of Medicine (M.D.). Section 26 proposes that no attendance at the university before passing the "first examination" shall be available for any degree, but that a power of dispensing with this rule, in special cases, be reserved. Section 28 proposes that, in each university, provision for the

teaching of French and German shall be made through the recognition by the University Court of Lecturers in these languages. Sections 31 and 32 suggest that, in the Universities of Glasgow and Aberdeen, there shall be instituted (among others) Professorships of Pathological Anatomy. Section 33 proposes that, in Edinburgh, the name of the Chair of General Pathology shall be changed to Pathological Anatomy, and that a Lectureship on Mental Diseases shall be instituted. In Section 36, a number of provisions for assistance and apparatus are proposed to be attached to several of the Chairs; *e.g.*, to the Chair of Physiology two assistants, one at £150 and the other at £100 a year; also a sum of £1000 for the purchase of apparatus and material of a permanent kind, with an annual sum of £100 for maintenance and provision of new material. To the Chair of Botany, two assistant-demonstrators, at £100 each, if the class number one hundred, and more, if necessary; and that, in Edinburgh and Glasgow, the classrooms of Botany be enlarged. There are similar provisions for assistants to the Professors of Natural History, Pathological Anatomy, Practice of Physic, and Clinical Surgery and Medicine. Section 39 provides that the Court of Curators in Edinburgh shall be enlarged by the addition of two members: one to be elected by the General Council, and the other the President of the Royal Society of Edinburgh for the time being, *ex officio*. Section 42 proposes that the patronage of the Chair of Botany in Edinburgh be transferred from the Curators to the Crown. Section 59 proposes that means be provided for enabling the University of Edinburgh to carry out its scheme for providing new buildings for the accommodation of the medical and scientific departments; and that the dissecting-room at Aberdeen be extended to suit the requirements of the Medical School. The report, before concluding, carefully points out which of these recommendations require the authority of Parliament to give them effect, and which of them may be carried out by the Universities themselves.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

**VACCINATION.**—Mr. Goodall of Silverdale has been awarded by the Local Government Board a Government grant for superior vaccination, amounting to £60 13s. This is the fourth award of a similar kind which has been received by this gentleman.

### THE CASE OF MR. BUCK.

THE following letter, dated March 23rd, 1878, has been handed to us: "Local Government Board, Whitehall, S.W.—Gentlemen,—I am directed by the Local Government Board to acknowledge the receipt of your letter of the 14th instant, respecting the claim of Mr. Buck, Medical Officer for the No. 3 District of the Saffron Walden Union, to a fee for attending on the child of a poor man named J. Wright. I am directed to state that the subject will receive the attention of the board.—I am, gentlemen, your obedient servant, HUGH OWEN, Junior Assistant-Secretary."

The letter is addressed to the Chairman and Secretary of the Poor-law Medical Officers' Association.

## MILITARY AND NAVAL MEDICAL SERVICES.

**SURGEON-MAJOR FALWASSER** has been placed by Mr. Hardy at the disposal of the St. John Ambulance Association to instruct classes at Chelsea. The steam-yacht of Lord Conyngham has also been made available for the purposes of the Association in the conveyance of men, nurses, and material.

### NAVAL MEDICAL SERVICE.

**SIR,**—As it is evident the Naval Medical Service still does not find favour amongst the schools, as shown at the recent examination for candidates for the department, and as it is well known that the last warrant, though a step in the right direction, fell far short of the recommendations that were offered to the Admiralty to quell the discontent which still continues, a few suggestions from one who has been some years in the service may be of service at the present time, when my lords must see the futility of temporising any longer. The principal points in the annexed scheme are those of retirement and the doing away of compulsory half-pay, which are of the greatest interest to us all. The promotion of surgeons to staff-rank and staff-surgeons to fleet-rank—the former after ten years' service and the latter after twenty years' service—is only what ought to be. These concessions,

together with the minor ones of cabin accommodation for fleet-surgeons, limitation of the time for holding appointments, and the selection of Director-General (which post few would wish to see done away with), would tend, in my opinion, to lessen the discontent reigning supreme at present through the ranks of the medical officers of Her Majesty's Navy.—I am, sir, your obedient servant,

A MEDICAL OFFICER ROYAL NAVY.

**Retirement.**—Inspectors-general to be compulsorily retired, as at present, at the age of sixty, on £2 *per diem*, without any qualification as to service whatsoever. Deputy inspectors-general to be compulsorily retired, as at present, at the age of sixty, on £1 : 13, without any qualification as to service whatsoever. Fleet- and staff-surgeons to be compulsorily retired at the age of fifty-five, on £450 *per annum*, without any qualification as to service, with the exception of half-pay time granted at an officer's own request, a deduction being made at the rate of £5 *per annum* for every three months of such time. Fleet- and staff-surgeons to be allowed to retire at the age of fifty on £400 *per annum*, with the same conditions as to half-pay time as the foregoing. All medical officers to be allowed to retire after twenty years' service on £300 *per annum*, with the same conditions as to half-pay time as the foregoing. All medical officers, if placed on the retired list through ill-health before attaining twenty years' service, to be retired as at present, but counting all compulsory half-pay time; if under fifty years of age, but having attained twenty years' service, to be allowed the option of retiring on £300 *per annum*, or as at present, but counting all compulsory half-pay time; if under fifty-five years of age, but over fifty, to be allowed the option of retiring on £400 *per annum*, or as at present, but counting all compulsory half-pay time. The same deductions to be made from the retired pay of officers placed on the retired list through ill-health for half-pay time granted at own request. Half-pay time granted while passing through a course at Netley to count towards retirement.

**Promotion.**—Surgeons to be promoted to staff-surgeons after completing ten years' service from the date of their entry into the service. Staff-surgeons to be promoted to fleet-surgeons after completing twenty years' service from the date of their entry into the service. Inspectors and deputy inspectors-general to be promoted, as at present, by selection.

**Director-General.**—The selection for this post to be made from the ranks of the active list of medical officers, and the time passed in office to count towards retirement.

**Appointments.**—All appointments to be held for a period of three years at least, and on no account to be exceeded, or for a commission.

**Cabin Accommodation.**—Fleet-surgeons to have special cabins told off, as at present in the case of chaplains, commanders, and paymasters.

**PUERPERAL ANTISEPTICS.**—Three papers by Langenbuch, Schülein, and Richter, in the *Zeitschrift für Geburtsh. und Gyn.*, report the extensive adoption of antiseptic measures for the prevention of puerperal infection in their respective hospitals. Richter's observations were made in the Charité Hospital at Berlin, where, especially after complicated labours, injections into the uterus were made for prophylactic purposes, and were continued throughout the puerperium. In all, about three thousand injections were made. The carbolic solution most frequently employed was a 2 per cent. solution. At first, a 3 per cent. solution was used; but, if repeated frequently, it was reduced to 2 per cent., as the former often caused carbolic acid to appear in the urine. Considering the numerous complications, the results were very favourable, being a mortality of 1.6 per cent. of all the women delivered, and of 4.83 per cent. among the cases in which the injections were used. Schülein, in the University Obstetric Clinic of Berlin, in the winter semester of 1876-77, treated two hundred and six out of two hundred and eighty-seven lying-in women immediately after delivery by prophylactic injections of the uterus with a 3 per cent. solution of carbolic acid. This injection was employed whenever in the lying-in bed frequent rises of the pulse and temperature occurred. A glass tube was at first used, and a double current catheter afterwards. Under this treatment, with eighty-one cases of illness among the two hundred and six, or 28 per cent., the deaths amounted to only seven, or 2.4 per cent.; only one occurring from septic causes, one in a woman on whom Cesarean section had been performed. Langenbuch has since 1872 employed drainage of the puerperal uterus in order to afford a free outflow of the secretions. His experience shows that this treatment is quite innocuous. In one case, the drain remained nineteen days *in utero*. He recommends this treatment where septic infection already exists, in order to prevent a new invasion of septic material; and also as a prophylactic measure when the cases seem to offer a doubtful prognosis.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, March 21st, 1878.

Dickson, Hammer, 26, Nelson Square, S.W.  
Fuller, Leedham Henry, 73, Denbigh Street, S.W.  
Hughes, David Arthur, 42, Leamington Villas, W.  
Marsh, Joseph Henry, Greenhithe, Kent  
Michell, Henry Sisman, Chelsea Dispensary, Sloane Square

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—At the ordinary monthly examination meetings of the College, held on Tuesday, Wednesday, and Thursday, March 12th, 13th, and 14th, 1878, the following were the successful candidates.—For the Licences to practise Medicine and Midwifery.

Burke, Andrew Joseph  
Collis, Robert William  
Denson, Joseph Leopold  
Dimond, John Elliott  
Edge, James Joseph  
Minchin, Robert William

For the Licence to practise Midwifery.

Alford, George Ernest  
Fogarty, Thomas Frederick W.  
Grew, Francis Blaney  
Hall, James Campbell

### MEDICAL VACANCIES.

The following vacancies are announced:—

**ALICE DALE INFIRMARY**, Cape Colony—Obstetric Physician. Salary, £500 per annum, with house, servants, and horse. Applications to be made on or before May 1st.

**ASHTON-UNDER-LYNE DISTRICT INFIRMARY.**—House-Surgeon. Salary, £80 per annum, with board and lodging. Applications to be made on or before April 17th.

**BOURNEMOUTH GENERAL DISPENSARY AND COTTAGE HOSPITAL.**—Resident Medical Officer. Salary, £120 per annum, with rooms, coals, gas, and attendance. Applications to be made on or before April 18th.

**BRISTOL GENERAL HOSPITAL.** Physician's Assistant. Salary, £50 per annum. Applications on or before April 19th.

**DEWSBURY AND DISTRICT INFIRMARY.**—House-Surgeon. Salary, £80 per annum, with board. Applications to be made on or before April 1st.

**EASTERN DISPENSARY OF BATH.**—Resident Medical Officer. Salary, £100 per annum, with furnished apartments, coals, gas, and servants. Applications to be made on or before April 16th.

**EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN.**—Resident Medical Officer. Salary, £60 per annum, with board, lodging, and washing. Applications to be made on or before April 11th.

**GERMAN HOSPITAL, Dalston.**—Honorary Assistant-Surgeon. Applications to be made on or before May 1st.

**LANCASTER INFIRMARY AND DISPENSARY.**—Salary, £120 per annum, with apartments, coals, gas, and attendance. Applications to be made on or before April 3rd.

**LEEDS PUBLIC DISPENSARY.**—Junior Resident Medical Officer. Salary, £80 per annum, with board and residence. Applications to be made on or before April 10th.

**MANCHESTER ROYAL INFIRMARY.**—Resident Surgical Officer. Salary, £150 per annum, with board and residence. Applications on or before the 31st instant.

**NARBERTH UNION.**—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.

**QUEEN'S HOSPITAL, Birmingham.**—Honorary Physician. Applications to be made on or before April 13th.

**ROYAL CORNWALL INFIRMARY.**—House-Surgeon, Secretary, and Dispenser. Salary, £200 per annum, with furnished rooms, coals, gas, and attendance. Applications to be made on or before April 24th.

**ROYAL FREE HOSPITAL, Gray's Inn Road.**—Senior House-Surgeon. Salary, £104 per annum, with board and residence.—Junior Resident Medical Officer. Applications to be made on or before April 3rd.

**ROYAL UNITED HOSPITAL, Bath.**—Resident Medical Officer. Salary, £100 per annum, with board and lodging. Applications to be made on or before the 30th instant.

**ST. MARY'S HOSPITAL, Paddington.**—Assistant-Surgeon. Applications to be made on or before April 4th.

**ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington.**—Pathologist and Medical Tutor. Applications to be made on or before April 8th.

**ST. THOMAS'S HOSPITAL.**—Ophthalmic Surgeon. Applications to be made on or before April 6th.

**WARNEFORD, LEAMINGTON, and SOUTH WARWICKSHIRE HOSPITAL.**—House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before April 16th.

**WEST SUSSEX, EAST HANTS, and CHICHESTER GENERAL INFIRMARY AND DISPENSARY.**—House-Surgeon. Salary, £80 per annum, with board, lodging, and washing. Applications on or before the 30th instant.

### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

#### MARRIAGE.

**SAWDO.—RAWSON.** On November 28th, 1877, at Hull, Frederick John Sawdon, M.B., etc., C.M. (Edin. Univ.), to Ann Eliza, second daughter of the late William Rawson, Steamship-owner, Hull.

### OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

### MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.**—Medical Society of London, 8.30 P.M. Mr. Squire, "Case of severe general Eczema treated by Phosphorus Alone" (living specimen); Mr. Teevan, "On the selection of an Operation for Stone in the Bladder".

**TUESDAY.**—Pathological Society of London, 8.30 P.M. Adjourned Meeting to consider Disease of the Lymphatic System. Specimens will be exhibited by Dr. R. Jones, Dr. Whipple, Dr. Goodhart, Mr. Nunn, Dr. Hoggan, Dr. Coupland, and Mr. Porter. Will be on view at 8 P.M.

**WEDNESDAY.**—Obstetrical Society of London, 8 P.M. Specimens: A Fetus whose Head was ruptured by means of the Forceps, by Dr. Cory; Cancerous Polypi removed during Pregnancy, with Microscopical Sections, by Dr. Galabin. Papers: Mr. Lawson Tait, "Two Cases of repair of the Female Bladder and Urethra"; Dr. Hickinbotham and Dr. Skinner, "Cases of Rupture of the Uterus";—Royal Microscopical Society, 8 P.M. Mr. J. W. Stephenson, "On a New Form of Object-glass".

**THURSDAY.**—Harveian Society of London, 8 P.M. Mr. Henry Morris's Report on Diseased Kidney. Dr. Griffith, "A case of Congenital Displacement of Heart" (living specimen); Mr. Teevan, "On the importance and means of effecting an early Diagnosis of Stone in the Bladder".

### LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

#### THE WOMEN'S QUESTION.

Under this head, an erudite correspondent draws attention to the following curious extract from the will of Mr. Thomas Axe, of Orchard, in the county of Somerset, which he recently copied from a tablet in the fine old church of Ottery St. Mary, Devon. It will, no doubt, be read with some interest by the "lady-doctors", for whom good "Maister Thomas Axe" appeared to have great respect. The will, which is dated July 20th, 1691, directs, amongst other good bequests, that of the profits of premises at Blandford, three-twelfths be given to some man or woman of exemplary life and some skill in physic and surgery, who should industriously endeavour to help all the poor of Ottery St. Mary gratis, in cases of sickness and accident, till better advice could be had. Testator's kindred were to be preferred for the office, the clerk's wife next, the vicar's wife before any other, if she should be very fit, or as fit as Mrs. Alford, the late vicar's wife. Maister Axe also directs all the profits of his "houses in Southwarke" to be divided into twelve parts, to be applied as set forth; then came marriage portions, etc., and one-twelfth to be given to the person before described to buy "drugges and plaisters".

**SIR.**—Could you kindly inform me whether chloroform is in some cases supposed or known to cause a skin-rash? A medical friend has had two cases lately, in which chloroform, in his opinion, was followed by an erythematous eruption. Both took the anæsthetic very well, with no subsequent sickness.—I am, yours truly,  
Gower Road, near Swansea, March 9th, 1878.  
D. G. P.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the **BRITISH MEDICAL JOURNAL**, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**ADVERTISERS are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the JOURNAL Office or any stated address other than a Post Office.**

#### THE BARBER FUND.

SIR,—I beg to acknowledge the following further contributions to this fund.

Dr. Tuckwell, Oxford..	..	..	£1 1 0
Dr. Smith, Ecclefechan, North Britain..	..	..	1 1 0
Dr. Fletcher, Earl Soham	..	..	1 1 0
G. Richard Pitcairn, Esq., Littleborough	..	..	1 0 0
E. G. Rendle, Esq., Sharrow, near Sheffield	..	..	5 0 0
A Friend	..	..	5 0 0

Latham House, Crickhowell, March 26th, 1878.

PHILIP E. HILL.

"DISPATCH", in making a suggestion of the kind, should append his name to the letter.

#### THE BRITISH MEDICAL ASSOCIATION AND THE LADY QUESTION.

SIR,—Pending the extraordinary meeting of the British Medical Association next month, I think it is only right that I should inform Dr. Markham, and others who are inclined to think as he does, and who forget that the by-laws of the Association are simply and solely for its guidance, that I have now ample legal counsel to sustain all that I have said, and my interpretation of the by-laws is in accordance with all societies' laws which have not an interpretation clause. According to civil acts, regulating such courts as our county courts, a clause of interpretation exists, so that *he* may be interpreted *she*, and the singular the plural, in case of need, etc. I deny, therefore, that *he* in our by-laws can be so construed, without the interpretation clause, as to include *she*. With these few words of explanation, your readers will see I have not entered upon the discussion without data to support even the expulsion of Mrs. Anderson and Mrs. Hoggan. It would then be for them to apply for a *mandamus* to the Court of Queen's Bench, and show their grievance and maintain what they, no doubt, call "their rights."—I am, etc.

Northallerton, March 25th, 1878.

HENRY BROWN, L.R.C.P., L.R.C.S.

#### MEDICAL ACTS AMENDMENT BILL.

SIR,—In the Medical Acts Amendment Bill introduced into the House of Lords last week, the registration of properly qualified dentists is sought for, and measures are indicated whereby the public may be more securely protected against the charlatanism of unqualified medical practitioners, but it contains no reference to the advisability of the registration of qualifications in public health. Does the course of medical study demanded at the present time by any of the licensing bodies include the various branches of hygiene? No. To meet this deficiency, several of our universities have recently instituted examinations in the subject. Why should the degrees or certificates obtained after such examinations not be registrable? Is it less important that local authorities should be without the means of ascertaining who have submitted successfully to an adequate examination test in matters relating to public health, than that the public should have the means of knowing who possess special diplomas in dentistry? I do not mean to insinuate that the present race of medical officers of health is incompetent. Many of them are masters in sanitary science; but the fact that they have educated themselves up to the highest pitch of excellence, is no proof that all practitioners, however eminent they may be as physicians or surgeons, are necessarily well qualified for the post of medical officer of health. Would it, then, not be advisable for the General Medical Council, or for the Committee of the British Medical Association, to again bestir themselves in this matter, and take measures whereby a clause would be introduced into the Bill to enable a degree or certificate in public health to be registered as an additional title by persons whose names are already on the *Medical Register*?—I am, Sir, yours, etc.,

JOHN CUNNINGHAM, M.B., S.C.Sc.Cert.Camb.

SIR,—Permit me to respectfully suggest to your Parliamentary Bills Committee the expediency of introducing into the above Bill a provision by which dentists would be restricted from employing anaesthetics without the presence of a qualified medical practitioner. I am fully aware that many dentists understand how to administer nitrous oxide; but I contend that the course of study gone through by those gentlemen who take a dental diploma does not qualify them to offer any opinion as to the existence of "fatty heart" or other contraindication to the use of anaesthetics. It is not long since a death took place owing to nitrous oxide having been administered to a patient (a medical man) labouring under "fatty heart". If dentists are allowed to give nitrous oxide without the presence of a physician or surgeon to-day, they will venture on ether and chloroform to-morrow, the more especially as "patients from the country", foreigners, and others may confound an L.D.S., who calls himself surgeon-dentist, with the qualified surgeon who follows dentistry, and who has gone through a more extensive physiological training.—I am, Sir, yours very truly,

FRANK THORPE PORTER, L.R.C.S.I.

15, Upper Merrion Street, Dublin, March 23rd, 1878.

MR. J. MARSHALL (Dover).—The subject in question is to be discussed at a special general meeting of the Association on Tuesday next, at which Mr. Marshall will be able to express his views, and where they can be discussed by those concerned.

#### CONSULTING PHYSICIANS AND GENERAL PRACTITIONERS.

SIR,—I should like to have your opinion on the following matter. A. and B. are medical practitioners in a large town in the south-east of England, of nearly the same age and standing, and old friends. A. is a "consulting-physician", being M.D.Lond.; B. is a general practitioner. About a year ago, A. was called in in consultation on a case in the family of a regular patient of B.'s. Very recently, B. discovers that A. is, and has been for some time, attending B.'s patient *alone*, without any intimation or notice of any kind to B. Now, I ask, is such conduct right? is it professional? is it honest? And, I should like to ask further, is it customary in other places?—Yours truly,

II.

\* \* Our correspondent's letter does not contain all the data necessary for the formation of an opinion. Does A. confine himself to consulting practice? or does he also undertake private practice, as many London graduates do? Is he attending the case by the express desire of the patient or otherwise?

HYGEIA.—It is impossible, by reason of the way in which the question is put, to answer it satisfactorily.

**CORRESPONDENTS** are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### ATTENDANCE ON THE FAMILIES OF MEMBERS OF THE PROFESSION.

SIR,—Whilst agreeing with many of the suggestions of a "Junior" in your last impression, I must take exception to the second clause having reference to attendance on medical men and their families. As one who has had considerable experience both "in giving and receiving" friendly and gratuitous service, I can conceive nothing more calculated to degrade our profession in the eye of the public than that suggested by "Junior". I cannot for a moment admit the case of clergymen paying others for preaching for them as parallel, as for the most part such services are rendered by men who, having no benefice, act as temporary substitutes. I do not, indeed, doubt that there are cases on record of rich men taking fees of poor clerical brethren; but this would, I submit, be no example to copy—not "doing as we would be done by"—and I have often wondered at the want of kindly and Christian feeling which withholds a retired clergyman from voluntarily supplying the place of a poor brother in ill health, to whom a change might be beneficial, but who cannot afford to pay a *locum tenens*. But this is not within our province to discuss, and I would fain hope that there are many, as I know there are some, honourable exceptions to this rule.

I can conceive no greater barrier to the growth of the kindly feeling which should exist between medical men than the practice of charging each other for advice. Imagine meeting your neighbour, when suffering from some slight ailment, asking him to look at your tongue, feel your pulse, and suggest a plan of treatment, and behold, next post brings a bill for 5s. or 10s., according to your friend's estimate of the value of his services. This would deprive of what I have always considered one of the greatest pleasures of my professional life, and, I may add, of what is generally regarded as a compliment to professional opinion. So far from my experience corroborating that of "Junior", "medical men in their inmost soul object to the present system", I can truly say that no medical man who has ever attended myself or family has ever acted in any way as though he expected a fee; but, on the contrary, has expressed himself as most pleased at having been able to render the service; and I have always acted in the same manner. I have, indeed, known a bill sent for attendance on a medical man's child, but such conduct was deemed most unprofessional. Of course, the gratuitous and honorary nature of the attendance does not prevent the receiver giving a suitable *honorarium*, according to his own pecuniary capacity and the length of the service, especially in cases of confinement, troublesome attendance, and long journeys. In one instance when I was asked, but declined, to send in a bill for attendance on the child of a leading London physician, I received a present far exceeding in value any money consideration I should have claimed of an ordinary patient.

I reside in a large city, and am at the present moment suffering from slight indisposition. A medical friend comes to see me, and a short time since I attended him. One of our leading physicians also saw him in consultation, but the question of payment has never once occurred to either of us, and if offered would be declined. There are other ways of showing our appreciation of kindness than by tendering "sordid dust", which, however necessary for the maintenance of existence, is not yet, I trust, the primary object of the right-minded members of our noble profession. I feel far more happy in my friend's "unpaid" hands than I should be if he were expecting to be paid, for he is constrained by a far higher influence than "cash"—viz., "love" for a fellow-creature and his glorious art. "Junior" must have fallen upon an unfortunate, and, I hope, singular place, as he got "badly attended" gratuitously. He does not specify whether the attendance was deficient in quantity or quality. If the latter, that was not the result of non-payment; but if the former, I can only say it is contrary to my experience both as giver and receiver, for I make a point of being extra attentive in such cases, and so has every one acted towards me.

I send my card in confidence, and would not object to signing my real name, were it not for my reference to another part of "Junior's" letter—viz., respecting gratuitous advice to non-professional persons, which, I regret to say, is given here freely by men occupying good social positions—one a hospital surgeon and in good practice—and this is done in the face of three hospitals and dispensaries, provident and improvident, and special institutions innumerable. This ought not to be, and is only an indirect way of advertising.

I see no objection to an arrangement being made on an equitable scale for attending the less wealthy classes by contract, although I am afraid that the complaint of our friend "Junior", of being "very badly attended", would often be made, and lead to occasional unpleasantness and change of doctors. Who is to decide the amount of a "day's pay" or a "week's pay" in the case of small tradesmen, who are often worse off than mechanics, artisans, or clerks? But I expect "Junior" will see cause to change his mind on many of these questions before he has become

March 5th, 1878.

"A SENIOR."

SIR,—I find a member has been placed in a similar position to myself. My case is this. My son, aged 16, resided about two years ago at a college twelve miles from my residence. He amongst others had the misfortune to suffer from an attack of measles, which was imported into the college by one of the pupils at the commencement of the term. In due time, the college and doctor's bill came to hand, and both were paid. This was not the first doctor's bill I have paid for attendance upon myself and family. From this it would appear to be the custom of some of the members of the profession to charge.—I remain, respectfully,

B. W.

SIR,—Will you permit me to make one or two remarks on the above subject? Within the last twenty-five years I have had occasion to consult for myself two surgeons and one physician, perfect strangers to me, and at their own houses. On each occasion I took care to have a fee in my pocket. All were well known in the profession and greatly esteemed. I did not present myself *incurio*. In each instance I tendered my fee, which in one case was accepted. My professional friends said it was shabby; but, on consideration, I arrived at a different conclusion. My card bore a name; it might have been stolen. My statement of being a medical man might be partly true and partly false. Why was I to intrude on the time of a brother practitioner? He could not verify my statements. I had brought no letter of introduction to say who I was. I was a casual visitor. Why was I to use *in forma pauperis* for gratuitous advice to an utter stranger? There are two classes of medical men—the credulous and the incredulous. The surgeon who took a fee was of the latter class. To him time was money. He treated me as a patient ignorant of his art, and took nothing for granted. The credulous, when they attend their medical brethren, are so afraid, from motives of delicacy, of appearing to dictate to a sick brother, that they give directions only so far; minor direction

are taken for granted as understood. When a medical man is sick, he is often very troublesome to his attendant, and requires ruling with a strong hand. Had "A Junior" been so ruled, he would not have called forth the deserved criticisms of "F.R.C.S." A medical man, then, and his family, in his own house naturally receives medical advice gratuitously; but he cannot expect the same indulgence for his family, or portions of his family, at school, at some distance, if he have not taken the trouble to ask his medical neighbour to be attentive to them, for they are not under a medical roof. The statement "I am a medical man, or the wife of one, or the child of one," requires verification, and should be known before attendance commences.

This question leads to a larger one—that of the out-patient department of hospitals, where, if verification of every patient by medical certificate were the rule, and medical men remunerated for their certificates by the hospital authorities as *bona fide* cases suitable for treatment or consultation, this overgrown department would soon be brought within reasonable limits.—I am, sir, yours truly,

March 16th, 1878.

ANOTHER MEMBER.

SIR,—Your correspondent "L.R.C.P." will find an account of my method of preparation in the appendix to the first of my series of "Researches on the Intimate Structure of the Brain" in the *Philosophical Transactions* for 1858.—I am, sir, your obedient servant,

21, New Cavendish Street, March 12th, 1878.

J. LOCKHART CLARKE.

W. B.—Wilson's *Manual of Public Health* (Churchill), Hart's *Manual of Public Health* (Smith, Elder, and Co.), and Parkes's *Hygiene*.

The following communications have been handed to the General Manager:—Mr. E. Ramsay, Liverpool; Mr. J. H. Parry, Bristol; Mr. J. H. Thomas, Wellingborough; Mr. S. S. Carter, Leeds (with enclosure); Mr. H. W. S. Worsley Benison, London; Mr. H. J. Jupp, London; Mr. R. T. Heuston, Dunse; Dr. Oman, Wishaw; Miss King, Bath; A. B., York (with enclosure).

#### MEDICAL REMUNERATION.

SIR,—I am surprised at seeing so frequently letters like that of "Pilgric" inquiring about medical remuneration, and think that the very excellent *Tariff of Medical and Surgical Fees* published by the Shropshire Ethical Branch of our Association, and sold by William Warrle of Shrewsbury, is not so well known nor so widely circulated as its usefulness deserves. The fees I charge are for the most part based on this tariff, and although they are higher than those of my neighbours, and I get occasional protests, I nevertheless keep my patients, and have plenty to do. I regard agricultural labourers as almost objects of charity, and charge them as low as possible, but try to insist on cash payments from them. If bills are neglected year after year, I threaten proceedings, and if this be unavailing, I issue a summons. I never get my claim opposed, and it is frequently paid into court. I do not find this summary method injure my practice; on the contrary, I am saved the trouble of attending those who do not mean to pay, and of subsequent attempts to make them do so. I hope more medical men will send for and adopt the medico-chirurgical tariffs, for the inadequate remuneration in many country districts is disgraceful and lowering to the profession.—Yours, etc.,

A MEMBER.

MR. WILLIAMS.—The election does not take place until the first Thursday in July. Mr. Edward Lund is in every respect most eligible, and, it is hoped, will respond to the proposed invitation. He is surgeon to the Manchester Royal Infirmary, and Professor of Surgery in Owens College. He was admitted a Fellow of the College by examination in June 1863.

DR. CAWLEY.—The bite of the viper is seldom fatal in this country, unless the subject is in a very bad state of health. Some years ago there was a fatal case at St. Bartholomew's Hospital, under the care of the senior surgeon Mr. Vincent.

#### KOUMISS.

SIR,—I shall esteem it a favour if any of your correspondents will give me detailed information as to the mode of turning milk into koumiss. I presume it is by means of some animal ferment, as in the Arabian koumiss of mare's milk.—Your obedient servant,

A PHYSICIAN.

MR. JONES.—The result was published in the *JOURNAL* immediately after the election in July 1871—viz., for Mr. Wells, 131; Mr. Critchett, 130; Mr. Clark, 127; and Mr. Busk, 117, who were declared duly elected. The unsuccessful candidates, Messrs. Holt and Cock, polled respectively 104 and 74.

#### EFFECTUAL TREATMENT OF THE HYSTERICAL PAROXYSM.

SIR,—As I was on my round of morning calls the other day, my attention was attracted by the gestulations of a woman, who earnestly entreated me to go at once into her house to see some one who was dying, or who was dead. I could not resist her importunity; and in the back room of her house found the assistant of a neighbouring firm mutely gazing on the prostrate form of a buxom lass in a paroxysm of hysteria. I at once began to administer abundant doses of cold water externally, *secundum artem*, with some slight effect, when I rushed the "family doctor," protesting that he could bring her about directly; and, true to his word, he did, and that most effectually. Having laid hold of a tuft of hair which graced her pubes, he gave it a vigorous tug. The effect was electrical: she immediately raised a most satisfactory howl, sprang at once on to her broad stern, and cried out most lustily for help.

Whether the above remedy was quite the thing, or whether it might not be included in the category of criminal assaults, I do not know. I never saw this remedy in the books; but it acted like magic.—Yours,

AN OBSERVER.

A SUBSCRIBER.—We do not know the value of the pictures mentioned.

#### HAMS AND MENSTRUATION.

SIR,—A circumstance has occurred recently in my house which I find explained by the letter of "A Member" in the *JOURNAL* of March 2nd. Some time ago, a pig was killed and cured, and the hams went bad. Two months afterwards, a second supply of pigs' legs was obtained, cured, and verified yesterday as perfectly good. On questioning my housekeeper, who cured both lots, I find she was menstruating on the former occasion, and not so on the latter. I also should be glad to hear of an explanation for so singular a circumstance.—I am, sir, yours truly,

March 11th.

ANOTHER MEMBER.

#### EXAMINATIONS IN SANITARY SCIENCE.

SIR,—In answer to your correspondent of last week respecting these examinations, I as a recent candidate would refer him for practical instruction to the hygienic laboratory of University College, London; and if he will arrange an interview with me, by addressing me at the College, I shall be pleased to give him all my experience as to necessary books, style of examination, etc.—I am, etc.,

C. D. A.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the *BRITISH MEDICAL JOURNAL*, should arrive at the Office not later than 10 A.M. on Thursday.

#### CHRYSOPIANIC ACID STAINS.

SIR,—I read with great interest Mr. Palmanno Squire's account of the means of getting rid of the stains produced by chrysophanic acid. I had come to the conclusion, after many experiments, that the acid forms with linen a perfectly fast dye. A friend who had used the acid gave me a fine pocket-handkerchief, which was stained in many places with the acid. I did not like to destroy the texture of the handkerchief; but I submitted it to every known bleaching process, with the effect of discharging the brown purple colour, but leaving dirty yellowish stains, which are far from being perfectly bleached. I had used the powerfully bleaching process of steeping the handkerchief in a strong solution of Beaufoy's chloride of soda, and also sulphurous acid, with Condy's fluid. When I read Mr. Palmanno Squire's letter in the *JOURNAL* of the 16th, I hoped to have found the desired process of bleaching. I accordingly steeped the handkerchief in a fairly strong solution of chloride of lime for thirty-six hours: at the end of that time the yellowish stains were still present, and not the slightest bleaching effect has taken place upon them. I am sorry to find this failure. It is possible that the acid does not make so fast a dye with cotton as it does with linen; and if time permit, I hope to make some experiments with a view to find the reason why a process succeeds in some hands and fails in others. Possibly old stains are more difficult to deal with than those freshly made.—I am, yours truly,

WALTER FERGUS, M.D.

Marlborough College, March 21st, 1878.

H. (St. Bartholomew's).—The registration having been abolished, you will not be required to attend as heretofore at the College of Surgeons during the last ten days of March.

MR. T. BRITTON (Birmingham).—At the Fattersea Provident Dispensary there are two classes of subscribers. Class A. includes those who are not earning more than 30s. a week: they pay 1d. a week. Class B. includes those earning from 30s. to 50s. a week: they pay 2d. a week. This plan was favourably noticed by Mr. T. Holmes, in his recent paper upon Provident Dispensaries (see *BRITISH MEDICAL JOURNAL*, March 16th), and might probably be adopted in many places with advantage.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Courant; The Middlesex County Times; The Liverpool Evening Albion; The Daily Courier; The Kelson Chronicle; The Fifeshire Herald; The Merthyr Express; The Carnarvon and Denbigh Herald; etc.

\*—We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

COMMUNICATIONS, LETTERS, etc., have been received from:—

Mr. James R. Lane, London; Mr. Furneaux Jordan, Birmingham; Dr. George Johnson, London; Dr. D. Ferrier, London; Mr. Vincent Griffiths, Twickenham; Dr. E. G. Levinge, Stapleton; Dr. W. Fairlie Clarke, Southborough; Dr. M. T. Sadler, Barnsley; The Secretary of the Royal Microscopical Society; Mr. J. H. Parry, Bristol; Dr. S. R. Potter, Culmington; Hygeia; A Subscriber, Bristol; Mr. R. Macnamara, Dublin; Dr. Dumontpallier, Paris; Dr. J. Clement Souter, London; Mr. Thomas Letts, London; Dr. Trevor Fowler, Epping; Dr. Clifford Alburt, Leeds; Dr. T. W. Hime, Sheffield; Mr. B. Browning, Rotherhithe; Mr. E. Frideaux, York; Mr. W. H. Michael, London; Mr. E. Ramsay, Liverpool; Dr. G. K. Poole, Anerley; Dr. Louis Lewis, London; Mr. Giles, Bristol; Mr. A. H. Benson, Dublin; Dr. Vinen, London; Dr. Corfield, London; Mr. C. Ashenden, Hastings; M.D.; Dr. A. B. Brabazon, Bath; Dr. Walter Fergus, Marlborough; The Secretary of the Statistical Society; Mr. A. Doran, London; Mr. W. H. # THE GOULSTONIAN LECTURES ON THE LOCALISATION OF CEREBRAL DISEASE.

Delivered at the Royal College of Physicians of London.

By DAVID FERRIER, M.D., F.R.S., F.R.C.P.,

Professor of Forensic Medicine in King's College; Assistant-Physician to King's College Hospital; etc.

## LECTURE II.—March 20th.

### A.—LESIONS OF THE MOTOR REGIONS.

THE motor area, as determined by experiments on monkeys, includes the bases of the three frontal convolutions, with those bounding the fissure of Rolando; viz., the *ascending frontal*, or *anterior central* (Ecker); the *ascending parietal*, or *posterior central* (Ecker), with its superior continuation, termed the *postero-parietal* or *superior parietal* (Ecker) lobule; together with the internal aspect of the same, which by our French brethren is generally called the *paracentral* lobule. (See fig. 1.) The homologous regions of the brain of the monkey and man are sufficiently evident not to require my taking up valuable time with any detailed anatomical description. In this region are situated certain definable areas stimulation of which by the electric current gives rise to certain definite movements on the opposite side—viz., of the leg and hand, facial, oral, and lingual muscles; and destruction of which causes paralysis of all those movements (*etc. etc.*) if the entire region be destroyed; limited or dissociated paralysis, if individual areas only be destroyed—the paralysis in this case being confined to those movements which are excited by irritation of the same. This region is supplied by the middle cerebral or Sylvian artery by four or five branches, each of which nourishes a special area. The artery may be occluded in its main trunk or in its individual branches; and the arrangement is such, according to the researches of Duret and Heubner, that the arteries of the basal ganglia may still remain pervious though the cortical arteries are occluded by emboli. Hence it is that softening limited to the cortical grey matter and subjacent medulla may and does frequently occur, while the basal ganglia remain absolutely intact.

The lesions which invade this region we may divide into *destructive* and *irritative*, in accordance with their main symptomatic characters. But a complete practical separation is not always possible, inasmuch as lesions which result ultimately in total disintegration are not unfrequently associated at times with irritative or convulsive phenomena limited or more or less generalised: a combination which may be likened to that in *anæsthesia dolorosa*.

We have now a very considerable body of evidence to show that destructive lesions of this region invariably cause paralysis of voluntary motion; and that there is a differentiation in this part of the cortex of distinct centres, corresponding in situation to those experimentally established in the brain of the monkey, destructive lesions of which cause limited or dissociated paralysis of their respective movements or muscular combinations. It is not maintained, however, that in all cases of purely cortical paralysis anatomical lesions are demonstrable in these centres; but I am unable, after much investigation, to find any satisfactory evidence of the occurrence of a destructive lesion here *not* associated with motor paralysis. I have met with occasional statements or hypotheses as to what may or must have been, but no proof of such a lesion having actually existed without paralysis.

Truly, Samt\* has recorded a case in which a cyst was found on the cortex in the motor zone; but, as Charcot and Pitres remark,† the actual destruction of the grey matter was not proved, since we know that tumours may press aside, without destroying, the tissue on which they rest. Let the subject, however, be investigated anew, with all the most modern methods, and with the utmost possible scrutiny. When a clear case of destructive lesion of the cortex in this region without motor paralysis is forthcoming, it will be time to cast aside the immense body of positive experimental and clinical evidence which we possess in favour of the thesis enunciated.

The experimental evidence in the case of monkeys is of the following nature. The brain is exposed. The application of that which is universally recognised as an excitant of nerves and nerve-centres to a certain spot is followed by a definite movement. All other conditions remaining the same, this spot is destroyed by the cautery (universally recognised as a destroyer of animal tissues), and immediately we see paralysis of the muscles formerly thrown into action by the electrical stimulus. I am describing no hypothetical experiment, but one actually performed and frequently varied. If motor function is ascribed to a nerve because on irritation the muscle contracts, and on section the muscle is paralysed, I cannot see why motor function should not be predicated of the cortical centre, seeing that the phenomena are essentially the same.

Brown-Séquard, however, thinks that, in all cases of paralysis from cortical lesion, there is some intermediate link or *tertium quid* intervening between the antecedent and the consequent: a kind of inhibitory influence exerted by the lesion on some centre or centres which are credited with the functions which are lost. It would, I think, be easy by parity of reasoning—and I say it with all due respect to the distinguished author of this theory—to make a complete *reductio ad absurdum* of the whole of experimental physiology. We should never be entitled to establish direct relationship between organ and function, but be condemned to a perpetual search after some *tertium quid*, which, like an *ignis fatuus*, would for ever elude our grasp.

It is generally considered that explanation is satisfied when we assimilate one fact or set of facts to another familiar fact or set of facts; and, if we are entitled to call a nerve motor because motion ceases when it is cut, so, it seems to me, we may call a part of the brain motor if a similar result invariably follow on its destruction.

I. *Destructive Lesions of the Motor Area*.—I will first direct your attention to destructive lesions of the motor area, and under this head consider (1) general and (2) partial lesions.

1. *General or Extensive Lesions*.—The type of general lesion of the cortical area in the monkey is paralysis of voluntary motion without affection of sensation on the opposite side of the body, and possessing all those features which characterise ordinary cerebral paralysis (*hémiplegie centrale vulgaire*, Charcot); viz., hemiplegia which, though at first absolute, gradually subsides into a condition in which there is complete paralysis of all the most volitional movements, while associated, alternating, or bilateral movements are more or less spared. Hence the hand is more paralysed than the arm, the arm more than the leg, and the lower facial movements more than the upper; while the muscles of the trunk are scarcely, if at all, affected.

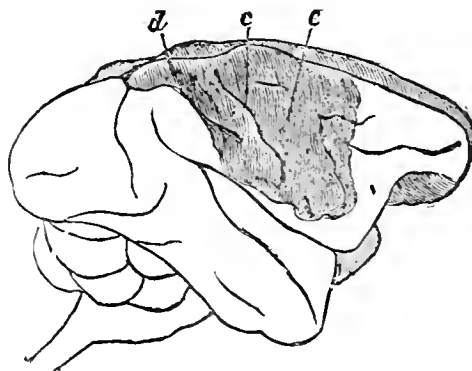

Fig. 7.

In fig. 7 is a representation of the extent of a lesion of the brain of the monkey causing complete hemiplegia of the opposite side. This was a case of encephalitis resulting from exposure, in which the phenomena in the early inflammatory stage were localised spasms on the opposite side, which gradually became general, followed by complete paralysis and flaccidity, without loss of sensation, when softening was complete.

Fig. 8 is a representation of a lesion causing\* paralysis of the arm and leg of the opposite side; and fig. 9 (f) represents a lesion in a region stimulation of which caused supination and flexion of the forearm. The result was paralysis of voluntary motion limited to this movement. These will suffice to indicate the difference between general and partial lesions of the cortex under circumstances free from all com-

\* *Archiv für Psychiatrie*, 1874.

† *Revue Mensuelle*, 1877.

\* Also temporary blindness of opposite eye, which will be explained below in connection with lesions of the angular gyrus.

plication. The lesions of disease, however, are, as a rule, rarely so simple. I have already indicated the forms of disease which can scarcely be admitted as relevant in relation to the question of localisation, and I would further add that considerable caution requires to be

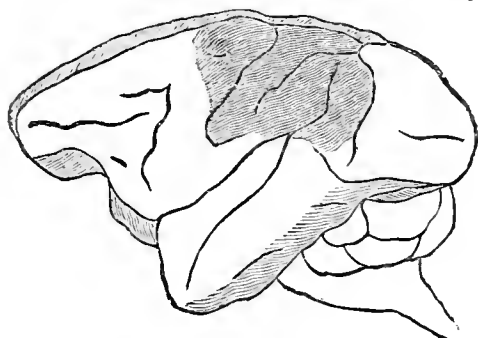

Fig. 8.

exercised in reference to traumatic lesions. These are most valuable in a negative point of view, as, for instance, in the case of the frontal lobes; but, when accompanied by positive symptoms, it is necessary that lesions of the base of the brain, which Duret shows may result from concussion and are apt to complicate the symptomatology of the local injury, should be shown to be absent.

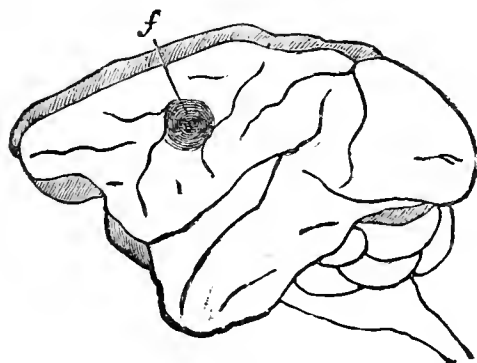

Fig. 9.

Apart from traumatic lesions, the cases of cortical disease which I proceed to quote clearly establish the fact that lesions in that part of the human brain which corresponds to the area termed motor in the brain of the monkey produce paralysis of voluntary motion on the opposite side of the body: a hemiplegia like that resulting from destructive lesion of the corpus striatum, or more particularly of the anterior part of the internal capsule (*hémiplegie centrale vulgaire*). This paralysis is frequently associated with rigidity or convulsive spasms in the paralysed parts, particularly in the early stage; and, if destruction of the cortical substance be complete, the paralysis is of permanent duration, and sooner or later is followed by late rigidity and secondary sclerosis of the motor tracts. This degeneration is traceable in the medullary fibres, crus cerebri, pons, and pyramid of the medulla oblongata on the side of the lesion; and thence mainly on the opposite side of the spinal cord in the posterior part of the lateral column (*faisceaux encéph. externes ou croisés*, Bouchard; *faisceaux latéraux*, Charcot; *Pyramiden Seitenstrangbahnen*, Flechsig); while a corresponding band of secondary degeneration frequently exists on the internal aspect of the anterior column of the same side as the lesion (*faisceaux encéph. directs ou internes*, Bouchard; *faisceaux de Türek*, Charcot; *Pyramiden Vorderstrangbahnen*, Flechsig). These are the tracts which recent researches, to which I have before alluded, have shown to be the continuations of the pyramidal strands; and the fact of the direct continuity of this degeneration with that commencing under the cortex proves, in accordance with Waller's and Türek's researches, the direct motor significance of the cortical regions to which these fibres are traced.

I have already mentioned the experiments of Albertoni and Michieli, and those of Franck and Pitres, showing that secondary degeneration occurs in the medullary fibres of the centrum ovale after destruction of the cortex in dogs; and I may also quote the experiments of Vulpian,\*

\* *Archiv. de Physiologie*, 1876.

and those of Carville and Duret, establishing the occurrence of secondary degeneration in the spinal cord after removal of the limb-centres—sigmoid gyrus—in this animal.

A case is reported by Gliky\* of unilateral convulsions of the left side followed by complete hemiplegia without loss of sensation, in which, after death, a caseous degeneration was found involving the ascending frontal and bases of the three frontal convolutions, the ascending parietal and postero parietal lobule, and the corresponding internal aspect of this region, or paracentral lobule. (See figs. 10 and 11)

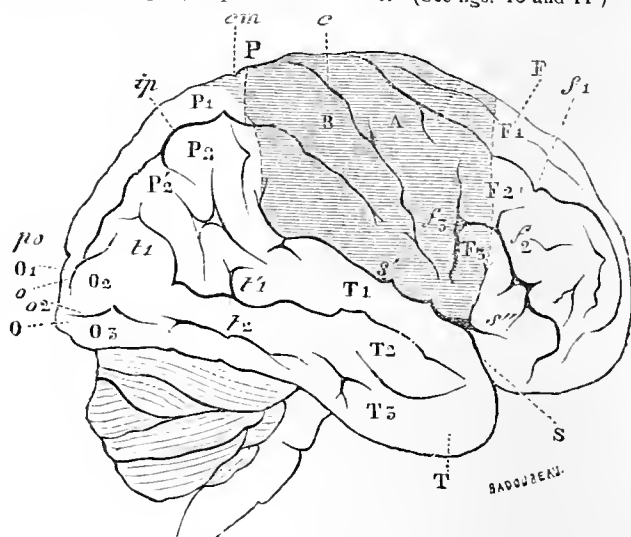

Fig. 10.

Lepinet† has recorded a case of right hemiplegia, without affection of sensation, of six years' duration, caused by yellow softening of the ascending parietal convolution in its whole extent, with partial affection of the ascending frontal, posterior digitations of the island of Reil, and

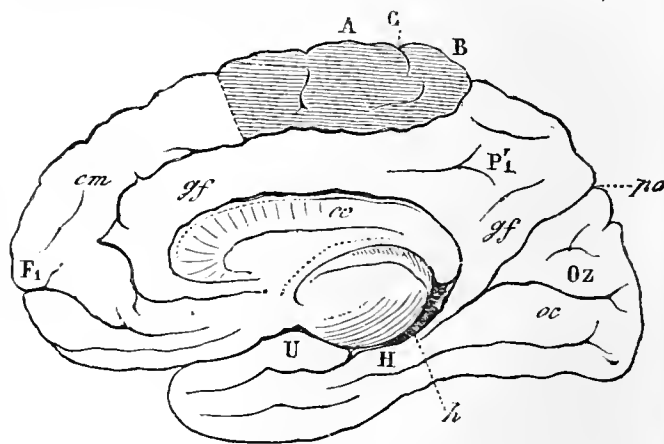

Fig. 11.

anterior part of the superior and inferior parietal lobule of the left hemisphere. The ganglia were intact. Secondary degeneration was traced in the left side of the pons Varolii and left pyramid.‡

In a case communicated by M. Brun to MM. Charcot and Pitres,§ left hemiplegia without aphasia had existed for four years, with late rigidity of the arm, and in a slighter degree of the leg. Yellow softening (*plaque jaune*) was found in the lower two-thirds of the ascending frontal, lower half of the ascending parietal, the posterior three-fourths

\* *Deutsches Archiv für Klin. Medicin*, December 1875.

† *Localisations dans les Maladies Cérébrales*. Thèse d'Agrégation, 1875.

‡ A mistake occurs in the account given of this case, which has been copied by MM. Charcot and Pitres, (*op. cit.*, p. 123), the atrophy being described as being on the right of the pons instead of the left. This is corrected by M. Lepinet's own hand in the copy which I possess.

§ *Op. cit.*, p. 121.

of the *second and third frontal*, and the whole of the convolutions of the island of Reil in the right hemisphere. (Fig. 12.) The ganglia

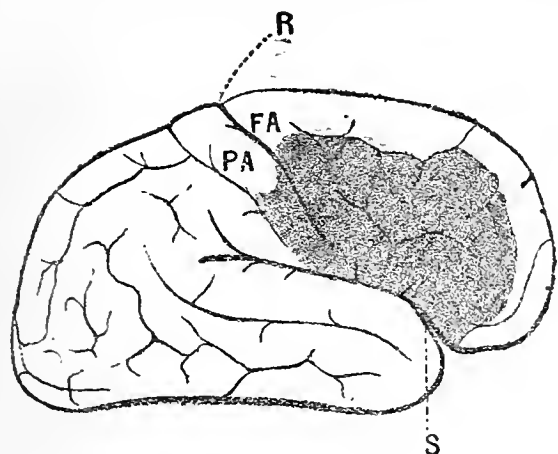

Fig. 12

were intact. No examination, however, was made in reference to secondary sclerosis in this case.

Another case is given by the same authors\* of right hemiplegia, with aphasia, of one year's duration, and accompanied by late rigidity of both limbs, more particularly of the arm. A patch of yellow softening was found involving the whole of the *ascending frontal* and base of the *third frontal* convolution, the whole of the *ascending parietal*, together with the inferior parietal lobule and two posterior digitations of the island of Reil in the left hemisphere. The ganglia were normal. Secondary degeneration was evident in the crus, pons, and pyramid on the same side; but the cord was not examined.

Trousseau quotes a case which occurred in the *clinique* of M. Charcot,† in which secondary degeneration was traced in the crus, pons, and pyramid of the same side as the lesion, and in the opposite side of the spinal cord; the lesion being, softening of the *ascending frontal*, the *third frontal convolutions*, and of the island of Reil in the right hemisphere. The case was one of left hemiplegia of three months' duration; death occurring from pneumonia.

These cases, out of many on record,‡ are sufficient to show that, from purely cortical lesions, permanent paralysis may result; that, in consequence of such lesions, secondary degeneration takes place in the motor tracts, with its accompaniment late rigidity.

In the cases I have quoted, there has been more or less complete hemiplegia. In some of these, the lesion has invaded the whole of the motor area, and it only; in others, the lesion of the motor area, though extensive, has not been anatomically coextensive with this area; and in most there has also been affection of parts not considered as belonging to the motor area. Clinical cases in which a lesion should be extensive enough to involve the whole motor area, and it alone, must naturally be considered as quite exceptional. But it is not at all difficult, by a process of exclusion, to eliminate those regions, a lesion of which does not cause paralysis or secondary degeneration; and it may be stated provisionally (of which proofs will be adduced subsequently) that it is only in cases of lesion of the motor area, as above defined, that secondary degeneration occurs, and only in these that paralysis is invariably the result.

I will return to the fact of complete hemiplegia, with comparatively restricted lesions of the motor area.

But before doing so, I would call your attention to the researches of M. Pitres, who, in his recent work,§ has collected a large body of evidence to show that what is true of the lesions of the cortical substance holds also in respect to lesions in corresponding parts of the centrum ovale; a term which he extends to the whole of the medullary substance intervening between the cortex and the basal ganglia. In all future observations and pathological records, it would be advisable to follow M. Pitres' system of nomenclature of the divisions of the centrum ovale. (See plate I in M. Pitres' work.) A vertical section of the hemisphere at right angles to the long axis in the prefrontal

region gives the *prefrontal section*. The next section, carried two centimètres in advance of the fissure of Rolando, passes through the bases of the three frontal convolutions and forms the *pediculo-frontal section*, divided into a *superior*, *middle*, and *inferior pediculo-frontal fasciculus*, corresponding with the respective frontal convolutions. The next section is the *frontal*, formed by dividing the hemisphere parallel to the fissure of Rolando through the ascending frontal convolution. Here also there are three divisions—the *superior*, *middle*, and *inferior frontal fasciculi*. (In this section, the sphenoidal region is partly shown.) Next is the *parietal section*, carried in a similar manner through the ascending parietal convolutions. Three segments are also seen here; viz., the *superior*, *middle*, and *inferior parietal fasciculi*. Next is the *pediculo-parietal section*, made by dividing the hemisphere three centimètres (1.18 inches) posterior to the fissure of Rolando, and cutting the superior and inferior parietal lobules. Here we distinguish a corresponding *superior* and *inferior pediculo-parietal fasciculus*. Below is the *sphenoidal fasciculus*. Section of the occipital lobe gives the *occipital section*, in which no separate fasciculi are differentiated.

Now, it is only in certain of the medullary fasciculi so marked out, that lesions cause paralysis of motion and degeneration of the motor tracts. These regions are included in the *pediculo frontal*, *frontal*, and *parietal sections*, or, generally, in the *fronto-parietal area*. Lesions here have exactly the same effect as lesions of the corresponding cortical region, according as they are destructive or irritative, or according as they are limited or general. And M. Pitres has brought forward evidence of a very satisfactory kind to show (p. 100 *et seq.*) that the early rigidity and muscular spasms, which so frequently accompany hemiplegia with effusion into the lateral ventricles, are essentially due to irritation of the fronto-parietal fasciculi of the centrum ovale.

As to the occurrence of hemiplegia with recent hæmorrhage into the fronto-parietal region of the centrum ovale, without direct affection of the cortex or basal ganglia, I might quote many cases; but, though the explanation is, through other facts, rendered simple enough, they may be objected to as evidence of paralysis from direct lesion of this area. For it might be said, and not without reason, that the paralysis was due to indirect affection, by pressure, etc., of the motor ganglia and tracts.

It will be better, therefore, to restrict ourselves to cases in which this element of suddenness or of pressure is entirely absent, *i.e.*, cases in which there was mere softening or solution of continuity of the medullary fibres.

Hodgson\* has related a case of right hemiplegia with aphasia, followed several months after the seizure with late rigidity of the right arm. Death occurred from chronic bronchitis more than a year after the attack. In the centrum ovale of the left hemisphere, was a cavity nearly empty, one inch and a quarter long, situated external to the lateral ventricle and between its anterior horn and the island of Reil. The rest of the brain, except the part immediately around the cavity (which was yellowish), was normal.

A similar case of right hemiplegia, but without aphasia, was recently brought before the Société Anatomique† by Landouzy. In this case, there was late rigidity and atrophy of the paralysed limbs. A slough formed in the sacrum, and death resulted six months after the attack. The lesion was a lacuna or cicatrix resulting from a hæmorrhagic effusion, situated in the centrum ovale, and extending from the base of the first frontal to the postero-parietal lobule. The form was irregularly triangular, the widest part situated posteriorly. Secondary degeneration was visible in the left crus and right side of the spinal cord, but the exact extent of the degeneration had not been minutely examined at the time the record was made.

For other similar instances, I would refer to M. Pitres' above-mentioned work.

2. *Partial Lesions of the Motor Area.*—a. *With Hemiplegia.* It would seem that, in order to cause more or less complete hemiplegia of the opposite side, it is not absolutely necessary that the anatomical lesions should be co-extensive with the whole motor area. I have already given one or two instances in which the lesion, though extensive, did not involve the whole of this region; to these I add one or two instances of hemiplegia in which the lesion was still more limited anatomically than in those already mentioned. But the area of anatomically demonstrated lesion is not necessarily the area of functional disturbance; and it is this element of uncertainty which, as I have before indicated, renders conclusions as to exact localisation, from a purely clinical point of view, always more or less doubtful.

There is, of course, no difficulty in accounting for complete hemiplegia in connection with very limited lesions of a *sudden* character in

\* *Op. cit.*, p. 121, *et seq.*

† October 1877. *Progrès Médical*, December 23th, 1877.

the motor area, such as hæmorrhagic extravasation or a traumatic lesion. In time, however, the symptoms generally disappear, with the exception of those attributable to the part immediately destroyed or irritated. But there are on record a few cases in which, though the lesions were of a more chronic nature and apparently anatomically circumscribed, a more extensive paralysis has existed than can be accounted for by the amount of cortex visibly destroyed.

MM. Charcot and Pitres\* give a case of right hemiplegia, without aphasia, but with facial paresis; and late rigidity of the limbs. The lesion was situated in the lower two-thirds of the ascending parietal

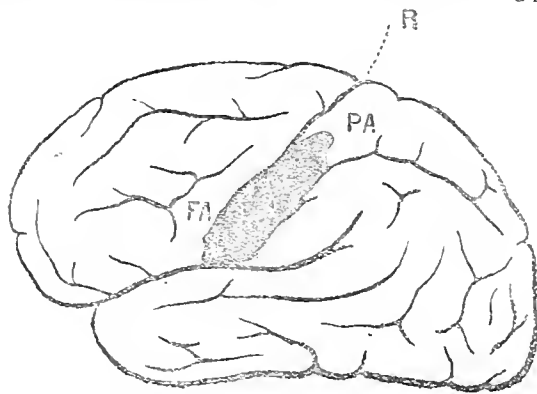

Fig. 13.

convolution of the left hemisphere (fig. 13). Secondary sclerosis existed in the motor tracts.

In another,† of right hemiplegia, without aphasia, and rigidity of the limbs (the paralysis alternating with unilateral convulsions), the chief lesion occupied the left paracentral lobule (fig. 14), which was

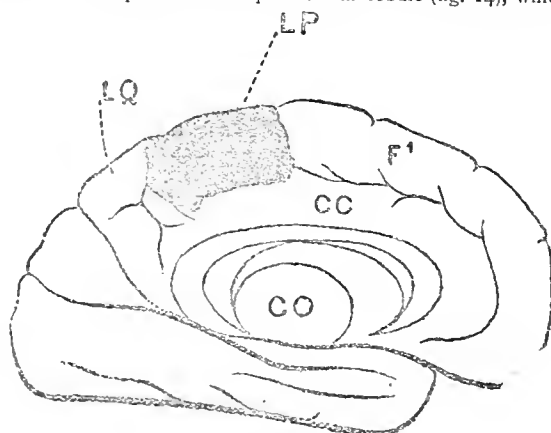

Fig. 14.

softened and atrophied. The lesion also involved the anterior third of the quadrilateral lobule and the upper extremity of the ascending frontal convolutions. In this case there were also other indications of degeneration in different parts of the hemispheres. Secondary degeneration of the motor tracts existed.

A similar case has been also reported by Pitres.‡

The first of these cases is the most difficult to account for, if the lesion were actually confined to the region indicated. The other two are more in accordance with the usual results of lesion situated at the upper extremity of the fissure of Rolando.

*b. Partial Lesions and Monoplegia.*—I will now proceed to lay before you some of the more carefully recorded clinical cases of limited lesions of the cortex with correspondingly limited paralysis or monoplegia of the movements governed by these parts respectively; and I hope to be able to show you that the situation of the various motor centres in the human brain closely corresponds with the position I have assigned to them on grounds of experiment and anatomical homology. But I would repeat that the observations on record are not yet sufficiently

numerous to establish by themselves, apart from the precise facts of physiological experiment, the exact situation and limits of these centres. With these facts, however, the case is altogether altered.

*Unilateral Oculo-motor Monoplegia.*—At the base of the first frontal, and extending partly into the second frontal convolution in the brain of the monkey, there is an area ([12] figs. 15 and 16) irritation of

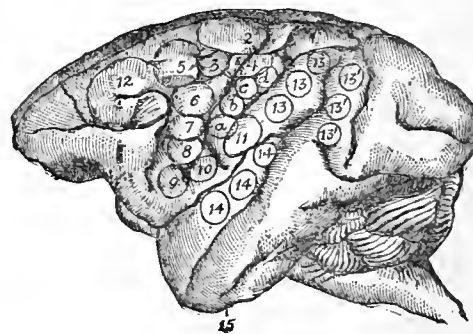

Fig. 15.

which causes elevation of the eyelids, dilatation of the pupil, conjugate deviation of the eyes, and turning of the head to the opposite side. I have placed these various reactions in the order in which they occur with slight and longer continued stimulation respectively. In the faintest form of stimulation, elevation of the eyelids is the only effect observable. Whether individual centres, incapable of sharp demarcation from each other for each of the movements indicated, exist here, has not been determined experimentally.

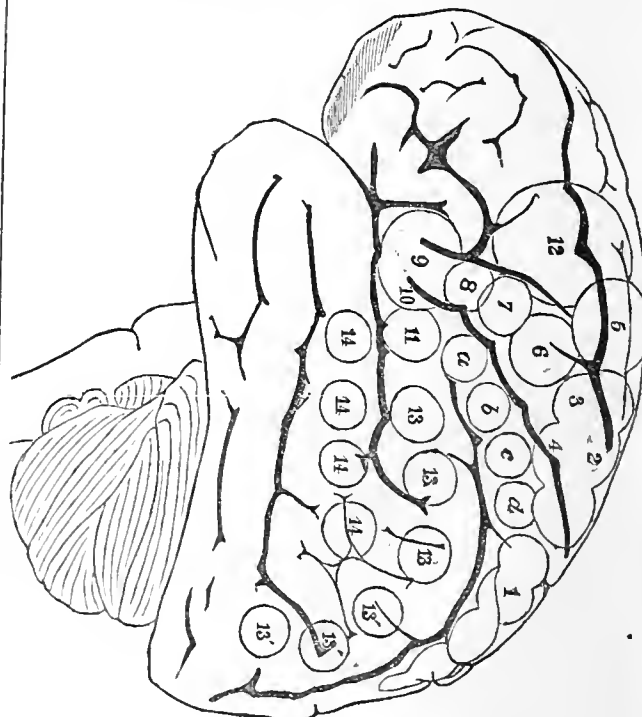

Fig. 16.

There are, however, clinical cases on record tending to show that there must be a distinct centre for the levator palpebræ superioris, inasmuch as paralysis may occur, limited to this muscle without affecting the other muscles supplied by the third nerve; an occurrence difficult to explain by peripheral affection of this nerve. Some such cases have been observed in connection with disease of the cortex, and attempts have been made, but not, I think, successful or in accordance with experimental lesions, to localise this centre in the angular gyrus.\* If such a centre really exist, I should be inclined to look for it in the

\* *Revue Mensuelle*, 1877, p. 191.

† *Op. cit.*, 1877, p. 193.

‡ *Le Progrès Médical*, September 19th, 1876.

\* Landouzy, "Biphéropose Cérébrale"; *Archiv. Gén. de Méd.*, August 1877.

region of which I am speaking. Still there are difficulties in the way; for affections of this region are not uncommon, and paralysis of the levator palpebræ superiōris without other oculo-motor paralysis is not so, or at least has not been often observed. Hence, if the centre of this movement exist here, its escape from paralysis needs explanation. Whether this can be found in the intimate bilateral association of the oculo-motor nuclei or not, is a question on which, as we have so little to go on, I forbear at present to speculate further.

In the case, however, of the bilateral and antagonistic movements of the head and eyes, it would be natural to look for lateral distortion should the centre in one hemisphere be suddenly removed; and the distortion would be towards the side of lesion, owing to the unantagonised action of the centre which remains. This affords a sufficiently satisfactory explanation of the conjugate deviation of the head and eyes observed in the early stages of hemiplegia, whether of cortical or ganglionic origin.

Certain facts, however, exist tending to show that this lateral movement of the eyes may be paralysed singly, or thrown into spasm singly, constituting what may be termed unilateral oculo-motor monoplegia or monospasm. This, even in the absence of a necropsy, would strongly point to cortical lesion, or lesion of the medullary fibres between the centre and the corpus striatum. It is only in such conditions that dissociated paralysis or spasm finds a satisfactory explanation.

This form of paralysis or spasm is by no means common—I find only three cases on record—and the actual *post mortem* evidence is still more scanty. Two such cases have been recorded by Priestley Smith.\* In one of these cases, the eyes were directed to the right, and the patient, though he possessed the convergent movements and power of accommodation, could not voluntarily move his eyes to the left. In the second, the eyes were also turned to the right, and inability to look to the left was also observed, as in the other.

Priestley Smith thinks that these cases are to be explained by either irritation of the opposite or destructive lesion on the same side of the centre I am describing. In this he is followed by Hughlings Jackson,† and with these views, I have to express myself as being in complete accordance. So far, they are perhaps speculative, as recovery took place in both cases.

The following case, however, related by Choupe,‡ which is quoted by Landouzy,§ supports this view by *post mortem* evidence. This was a case of a lad, aged 19, who showed symptoms of tubercular meningitis, in which, in addition to pain, vomiting, etc., the most remarkable symptom was a rotation of the head and eyes to the right. This could be overcome with moderate effort, but the head and eyes returned to their position when left to themselves. No other paralysis or contracture existed elsewhere. After death, a patch of disease, free from granulations and quite superficial, of the size of a franc piece, was found on the "superior part of the middle frontal convolution" in the left hemisphere. Other lesions were found in the superior and lateral part of the sphenoidal lobe of the right hemisphere, but, as will be subsequently shown, these cannot be regarded as much complicating the case. There was no other cerebral lesion. The exact situation of the lesion in the left hemisphere is not indicated more precisely than in the words quoted; but they may, I think, be taken in support of the theory that these special symptoms were due to irritative lesion of that which corresponds with the oculo-motor centre in the brain of the monkey.

**Crural Monoplegia.**—As there seems to be some misapprehension abroad in reference to the centres of movement of the hinder extremity, let me first call your attention to the facts of experiment. Irritation of the *postero-parietal* or *superior parietal lobule*—area 1—(fig. 15) causes flexion of the foot in the ankle, occasionally combined with flexion of the thigh on the pelvis, and extension forward of the leg as in the act of walking.

On the other hand, in my experiments on monkeys, stimulation of area 2 (fig. 15), a region which includes the upper extremity of the ascending frontal, as well as part of the ascending parietal, gave rise to more complex movements, the result of which was to bring the foot towards the middle line of the trunk, as if the animal were to scratch its abdomen or lay hold of something in this position. The area 3, near it, gave rise to movements of the tail. Below it (4), certain movements of the arm—viz., adduction and retraction—were excited.

It is a question by no means easy to answer *à priori*, how far the movements of the human leg can be compared with those of the leg-arm and foot-hand of the monkey; or what is the representative in man of the centre for the tail which, in the New World monkeys, plays the part of a hand. We must, therefore, be cautious in drawing

conclusions as to the exact position of the arm and leg centres in man from considerations merely of anatomical homology. And there is reason for exact and careful analysis of the movements which are affected, or more particularly affected, in any given case of crural monoplegia of cortical origin, for on this may depend the exact regional diagnosis.

Clinical evidence in favour of a distinct centre or centres for the leg, clearly differentiated from those of the arm, is not as yet very extensive. We have many cases on record in which the leg and arm have been paralysed together—brachio-crural monoplegia—an association easily accounted for by the close relation of the leg and arm centres to each other. Still, there are some cases in which the leg *only* has been paralysed; and in others, in which leg and arm have been ultimately conjointly affected, the paralysis has shown itself *first* in the leg. This latter fact has an important bearing on the question of a distinct leg-centre, and its exact situation. A few cases are on record of paralysis occurring in one or both legs from injury to the vertex in the parietal region; but we cannot exercise too much caution in the inferences we draw as to the seat of lesion in such cases. The researches of Duret\* have shown that local and general spinal paralyses may result from bulbar and spinal lesions owing to sudden displacement downwards through the aqueduct of Sylvius of the cerebro-spinal fluid in consequence of blows on the head. A case in which, from the symptoms, this was evidently the mode of causation, is related by Guthrie.† A soldier at Waterloo was struck by a shot which caused depressed fracture of both parietal bones. On his recovering consciousness, he was found paralysed in both legs, and benumbed from the loins downwards. He recovered on being trephined ten days afterwards. It cannot be doubted that the paralysis in this case was spinal paraplegia, and easily accounted for in the manner demonstrated by Duret.

In some other cases, however, the lesion may have been cerebral; the fact of the paralysis being crossed would support this view. Hitzig‡ quotes from Löffler the following among others. A Danish corporal was struck by a shot at the *superior and posterior extremity of the left parietal bone*, close to the sagittal suture (overlying the postero-parietal lobule, see fig. 3). The right leg was immediately paralysed. The right arm became affected on the seventh day. On trephining, recovery took place—the arm first, and then the leg. This may fairly be taken as a cortical lesion, as the subsequent affection of the arm is in accordance with extension of softening to neighbouring centres; a feature so characteristic of cortical lesions. Another case of fracture of the "summit of the right parietal bone" by a shot was followed by paralysis of the left leg.

As cases of disease of the cortex with crural monoplegia, the following two (though they are not altogether precise) may be taken, quoted from Landouzy.§ One is reported by Becquerel, of paralysis limited to the left leg. The lesion in this case is described as being situated "at the upper part of the right hemisphere", consisting of granulations and adhesions (p. 211). Slight affections of the pia mater and sub-jacent cortex were, however, also observed in the left hemisphere. The second is recorded by Rendu. This was a case of paralysis of the right leg followed by paresis of the right arm, which gradually increased. In the *parietal convolutions* of the left hemisphere, *close to the longitudinal fissure*, was a zone of exudation and interstitial hemorrhages, affecting both the cortex and medullary substance to a considerable depth, but not extending to the basal ganglia. In the parietal convolution (exact position not stated) was found a caseous nodule of the size of a nut. It is, however, to be noted that the cerebral membranes generally in both hemispheres indicated signs of tubercular meningitis. Hence, the case is not quite free from complication.

I may here mention a case which, though one of tumour, has a considerable value in reference to the question before us. The particulars were privately communicated to me by Dr. Haddon of Manchester, and the question arose during life as to the exact locality of the tumour and the advisability of trephining. Though our diagnosis proved absolutely correct, the operation, for other reasons, was not performed. The patient began first to have tingling in the left leg, followed by paresis of this limb, gradually increasing, and continuing restricted to the left leg for five months. Then the left arm became weak. After occasional attacks of rigidity and twitching, the arm and leg became both completely paralysed. Shortly before death, signs of weakness showed themselves also in the right leg. After death, a tumour, three inches in diameter, was found growing from the dura mater, and pressing perpendicularly downwards on the region included in the *upper extremity*

§ *Op. cit.*, p. 211-212.

of the *ascending frontal*, *ascending parietal*, and *postero-parietal* convolutions. The tumour had grown downwards as far as the floor of the lateral ventricle, compressing the brain-substance in its course. It also impinged on the other hemisphere. The point of origin of this tumour, and the mode of growth, warrant the conclusion that the paresis of the left leg, which was the first and for a long time the only motor symptom, was due to the affection of the cortex in the region where experiments in the monkey would lead us to localise the leg-centres.

I will mention, lastly, two cases reported by Bourneville, which, though not uncomplicated cases of crural monoplegia, yet deserve to be taken in consideration with the others. They might also be referred to as instances of partial hemiplegic epilepsy. The first of these\* is quoted by Charcot and Pitres. This was the case of a girl, aged 13, who had been affected with infantile hemiplegia of the left side at the age of four. She was subject to epileptic attacks, beginning in the left leg, which was paralysed. There was no facial paralysis. After death, a patch of degeneration was found in the right hemisphere, occupying the upper half of the ascending frontal, the bases of the first and second frontal, the anterior part of the postero-parietal lobule, and the whole of the internal aspect of these regions (fig. 17). Secondary

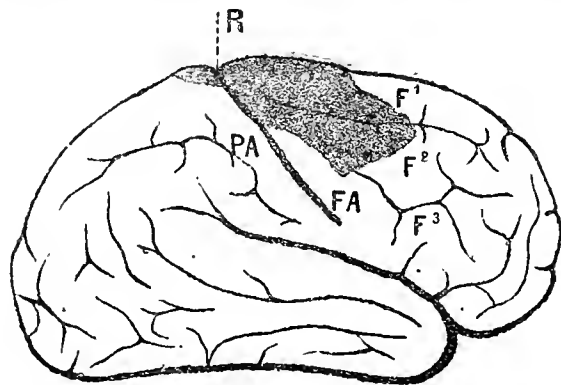

Fig. 17.

degeneration of the motor tracts of the spinal cord existed. The second case was a similar one of infantile hemiplegia, followed by partial epilepsy; the spasms being limited to the right leg, but gradually invading the right arm and the right side of the face. The position of the lesion, diagnosed during life, was the *upper extremity* of the (one *cent.* in extent) *ascending frontal and parietal convolutions*, and the internal surface corresponding, or paracentral lobule. This region was the seat of softening. No other lesion existed. In this case also, secondary degeneration was found in the right half of the spinal cord, in the postero-lateral column.

These cases, I think, suffice to prove that the lesions which have been described in connection with crural monoplegia very closely agree with the position of the centres for the movements of the leg in monkeys. In the absence of other cases of lesion serving to determine the exact position and extent of the leg-centre, M. Bourdon† has endeavoured to arrive at this by another method. The method he adopts is to examine the brain in cases of amputation or arrested development of the lower extremity, with the expectation of finding atrophy of the corresponding centre, in accordance with Luys' views. Whether these expectations are altogether justifiable may be questioned.

But, theoretical considerations apart, the practical difficulties in the way of a satisfactory solution of this problem are very great, and I do not think that, up to the present at least, they have been disposed of successfully. An important communication on this subject was recently presented to the Société de Biologie (January 5th, 1878) by M. Féré, well known for his valuable researches in cerebral topography. M. Féré shows that neither the method of ascertaining the existence of atrophy, by comparing the relative size of homologous convolutions in each hemisphere, nor that founded on the advance or recession of the fissure of Rolando (round which the motor centres are grouped) is reliable; inasmuch as in the perfectly normal brain there are great variations and want of symmetry in the convolutions and fissures in the two hemispheres, and there is no absolutely constant relation between the position of the fissure of Rolando and a certain cranial region, or in its position in the one hemisphere as compared with the other. Hence

the necessity of receiving all statements with regard to atrophy with extreme caution, unless substantiated by a thorough microscopic investigation of the parts said to be so affected.

With these considerations, I will now give the results of M. Bourdon's analysis of cases of amputation. In one of amputation of the thigh, thirty-five years before death, atrophy was said to exist at the upper extremity of the ascending frontal, at its junction with first frontal convolution of the opposite hemisphere. In a second, of amputation of the thigh, fifty-two years before death, atrophy was said to exist in exactly the same situation. In a third, of amputation of the thigh, twenty-one years before death, a linear depression was found interrupting the continuity of the second frontal convolution in the opposite hemisphere.

To these cases, which M. Bourdon quotes from M. Luys, a fourth is added, observed by M. Landouzy. This was a case of arrested development of the right leg at the age of eighteen months, death occurring at the age of forty-five. The left hemisphere was smaller than the right, and the fissures of Rolando were unsymmetrical. The left ascending parietal convolution appeared somewhat smaller than the same convolution in the right hemisphere. There was also asymmetry of the pons and medulla, the left side being the smaller.

None of these cases appear to have been investigated microscopically. If we regard them as satisfactory, which I think we are scarcely entitled to do, we do not find any more exact correspondence as regards the situation of the leg-centre, than in the cases of lesion already mentioned. I think, however, that, though the exact limits are not defined, the evidence points to a position closely in harmony with that defined in the brain of the monkey; and that the conclusion formed by M. Lucas-Championnière is well justified, viz., that, to expose the leg-centre, it is necessary to apply the crown of the trephine over the upper extremity of the fissure of Rolando.

[To be continued.]

## CLINICAL OBSERVATIONS

ON A

### FAILURE IN THE ANTISEPTIC MANAGEMENT OF A CASE OF EMPYEMA.

By JOHN DUNCAN,

Surgeon to the Royal Infirmary, Edinburgh.

GENTLEMEN,—On November 20th, 1877, Dr. Balfour sent to us for operation a patient who had been admitted to the medical house, suffering from empyema. The vicissitudes in her history since she came under our observation deserve your attentive consideration.

Four years ago, she had a severe attack of pleurisy, from which she never completely recovered; but she dates her present illness from exposure to cold six months before admission. Pus was three times drawn from the chest by means of a Bowditch's syringe while she was under Dr. Balfour's care; but the relief was only of temporary duration. On November 23rd, I made a free incision between the sixth and seventh ribs in the axillary line, and evacuated a quantity of pus, which my house-surgeon (Mr. Black), partly from measurement, estimated at more than three hundred ounces. Those of you who were present will remember the extraordinary force with which the matter was projected the moment the cavity was opened. For the next month, the progress of the case was all that could be desired. The temperature, which, before the operation, had varied between 99 deg. and 101 deg., fell to normal, and the highest reading recorded is 98.8 deg. The discharge rapidly diminished until only about a tablespoonful daily (probably less) of sero-purulent fluid came away by the drainage-tube.

On December 23rd, we dressed the wound under the spray from a new steam spray-producer, which we afterwards found had been discharging a carbolic solution of about one to a thousand, on account of the imperfect boring of the nozzle. You may recollect that I then speculated on the probable consequences, and it is certain that my fears were speedily realised. Next evening, the temperature stood at 100.6 deg.; and perhaps I cannot give you a more graphic description of the condition of affairs than by reading to you the morning and evening temperatures of the next few days.

\* Gazette Médicale de Paris, December 1876.

† Recherches Cliniques sur les Centres Moteurs des Membres. Paris, 1877.

At the same time, the discharge at once became thickly purulent, and, in three days, had increased to fifteen ounces *per diem*.

I need not detain you with a further history of the case. It is the record of a struggle to perfect the drainage by elaborate washings out, by various forms of tubing, and by suction-apparatus. With it all we have only been partially successful. The patient is now doubtless recovering; but her wasted condition shows the drain upon her system made by the constant copious discharge and by the feverishness, which we have never been able entirely to subdue.

There are many points in the case to which I should like to draw your attention. I should like, for example, to compare with you the effects of great tension in this and other cases on inflammatory action and temperature, and to discuss the best methods of securing efficient drainage of these large cavities. But, for the present, I think it better to confine my remarks to one subject: the bearing of the case on Mr. Lister's method of treating wounds.

And, first, it appears to me to bear a remarkable testimony to the value of the method, and to the truth of the theory on which it is founded. Let us look at the facts. After a month of uninterrupted progress, we recognise a defect in our manipulations; are alarmed for the result, and have our fears speedily and very seriously confirmed. I cannot escape the conclusion that there was here a relationship of cause and effect, and, if so, it is a proof of the practical value of antiseptics more convincing than many records of successful cases which possibly may be paralleled under other modes of dressing. But, as if to make assurance doubly sure, on the same day, the same spray-producer was used while I excised a mamma; and in this patient also the signs of putrefaction were speedily apparent. It becomes impossible to suppose that mere coincidence could account for the double sequence. But I think our case carries us farther. Most surgeons admit that antiseptic dressings are perfectly wholesome and safe; but a curious variety of attitude is assumed with reference to the special advantages claimed for them, and the reason of their success. Some hold that carbolic acid acts by diminishing the vital activity of the textures; others that it alters, as smoking a ham does, the conditions favourable to the development of the bacteria of putrefaction. But, if it be admitted that the defective spray was, in the case before us, the cause of the evil results, what other hypothesis can be framed to account for it than that on which the antiseptic system is founded? How, for example, could the spray modify the vital actions or alter the developmental conditions of the parts within the thorax which it never reached? If bacteria and putridity came from within (and it is impossible to deny that sometimes it may be so), how could the pumping of a more or less carbolised spray outside the chest-wall affect their presence? Or, if the noxious agent came from without, what other constituent of the air than organic germs could be thus affected? In short, if the spray be of real value—and these cases seem to prove that it is so—the conclusion seems inevitable that putrescence is the chief of surgical evils; that it is the product of bacteria, and that, in the immense majority of cases, bacteria come from without.

But now, gentlemen, having looked at our case from one point of view as a striking illustration of the truth of the antiseptic system of surgery, I think we may also learn some lessons from it as an example of the failure of the system.

As a practical method, there can be no doubt that this is a weak point. Success depends on careful attention to a series of minute details, the failure of one of which vitiates the whole procedure. Like a chain, its strength is equal only to that of its weakest link. Under such circumstances, occasional mistakes are as certain to occur as occasional accidents on a railway; and, from the same causes, the deficiencies of our mechanical appliances, and especially the fallibility of the human agency concerned in the manipulations. I need hardly say that a thousand errors are no proof of the necessary falsity of the system. If, by other means, it be proved true, practical success or the reverse bears only on its application and applicability. But frequency of failure might necessitate its abandonment, or at least be a strong argument against its usefulness. It would necessitate abandonment if, in failure, the system proved injurious. It does so under certain circumstances. In compound fracture, if the injection be successful, the subsequent progress of the case is most remarkable in many ways, and singularly beautiful; if it fail, my experience is that the effect is very disastrous; and it is often a most difficult problem to determine whether or not to treat antiseptically when some hours have elapsed after the injury. But, in the vast majority of instances, no such question arises. If antiseptics do not prevent putrefaction, the worst that can be said of them is, that they are useless. Nay, I believe that, in some respects (I need not enter into details), they are absolutely beneficial to the patient, and are certainly advantageous in preserving the general amenity of the atmosphere.

But yet again, frequent failure might make antiseptics valueless in comparison with the cost, the labour, or the success of other and incompatible methods. I say incompatible, because, of course, whatever may be advantageously combined with this method ceases to be a rival to it. In this connection especially, the question of frequency arises. Men are not prone to publish their mistakes; but I believe that a statistic would be useful showing the frequency with which antiseptics fail in the hands of men of ordinary intelligence, who are determined to carry out the system on the basis of its fundamental hypothesis.

Here let me digress a little to point out to you certain difficulties which stand in the way of obtaining such a statistic. There is an indubitable difficulty in determining what are and what are not aseptic cases. There is a broad margin of doubtful ground which prejudice on this side or that is prone to arrogate to itself. Let us consider the grounds on which the distinction is to be made. It is evident that neither the general condition of the patient nor the healthiness of the wound can be accepted as criteria for such a comparison. That would simply beg the question. We must have distinct evidence that the discharges are or are not septic. Now, this is not so simple a matter as you would at first be inclined to suppose. The odour is not a reliable test, and for two reasons: one is that many aseptic cases, from chemical changes in sebaceous or other secretions, from reactions between these and the contents of the dressings, and from other causes, produce odours which, to say the least, are often exceedingly disagreeable; another is that the injurious products of putrescence, although frequently associated with disagreeable odours, do not themselves emit them, and are not their necessary concomitants. In five cases, I have failed during the past *semestre* to preserve wounds from putrescence by means of carbolic acid. In the case which affords the text for these observations, and in one other, there was no disagreeable odour whatever, although the discharge was very copious. In the mamma to which I have already referred, the most odious butyric smell pervaded everything. In a fourth case, that horrible smell, which is attributed to indol, could not be prevented with the utmost care; and, in a fifth, yet another variety was unpleasantly perceptible. I feel tolerably certain that some odours indicate putrefaction, and I think it likely that education may do much to produce an appreciation of the differences which exist between them and others, just as it enables some men to tell with remarkable certainty the vintage of a first-growth claret. But I feel equally sure that putridity may produce its noxious results without thus manifesting its presence; and I frankly confess that, in a large proportion of our cases, I do not succeed in coming to a conclusion by the unaided sense of smell.

But you will say the microscope should enable you to put your mind at once at rest. To a certain extent, you are right; but it is not so easy as many of you might be inclined to think. There is a class of spontaneously moving bodies, in shape and appearance closely resembling bacteria, which occur, it seems to me, with equal frequency in discharges which, on other grounds, might be pronounced septic and aseptic. I think distinctions may be seen in their refraction, the character of their movements, and their uniformity of size; but I own to having at first received a shock to my beliefs in watching these bodies. I fancy, however, that we have in acetic acid a means of distinguishing them more definitely. I had heard that this method had been tried by others, and I have been pleased to find that, if you apply it to a slide on which vigorous bacteria from putrid water are disporting themselves, you only slowly arrest their movements; but, if you bring it into contact with the bodies of which I speak, they rapidly dissolve and disappear. I have not yet satisfied myself by a sufficient number of observations; but I believe this to be the case, and, if so, the microscope becomes a reliable test: only, however, negatively reliable. There are septic discharges in which you will find no bacteria. I have watched discharges daily in which they were abundant, and have frequently found that they diminish in size and number, and ultimately become completely invisible to the ordinary powers of the Hartnack's microscope. In our present patient, for example, it is only within the last few days that the field of view has not swarmed with moving rods. This is coincident in her with general improvement; and I think it corresponds usually with a return to health, a reacquisition by the tissues of that power whereby the multiplication of these low forms is prevented in them and in contact with them. But, however that may be, you will see that we cannot absolutely decide by means of the microscope between septic and aseptic cases. We must assist it by other means, of which doubtless there are many. Thus the presence of sulphuretted hydrogen may be detected by chemical measures or indicated by blackening of the protective. But it is not pathognomonic; it is not always present with bacteria, and it may be present when they are absent; and the same may be said of ammonia, on which some have laid great stress. In short, I suppose (at least until the law

against vivisection is improved away) that we have no certain, clear and easy test for the pyrogenous and phlogogenous products of the growth of bacteria, simply because we do not know them, but only their frequent concomitants.

Well, then, you can understand that, when I say it is desirable to have some idea of the frequency with which antiseptic treatment fails, I desiderate what is not easy of attainment. Having no absolute test, we attain certainty of asepticity only by ascertaining that the testimony of all the tests I have mentioned is coincident. Now, I do not think that the statistics which have been published fulfil this rigorous requirement. They have been used to show the general goodness of results under antiseptic management, and doubtless in that view they have a certain value of their own. And here let me say that the idea which appears to possess some men, that the questions which underlie the antiseptic method, or its value, can be at present determined by general and comparative statistics, seems to me curiously erroneous. In those confusingly able lectures of Dr. Burdon Sanderson lately published, much stress is laid on the abolition, in certain German clinics, of septicæmia and pyæmia. Such facts are of some value, I admit; but, when we consider the mass of septic cases that necessarily remains in every hospital, and the uncertainty, which I have just pointed out, as to the proportion of failures, it is evident that other factors (better drainage, greater cleanliness) have also been at work; and I will venture to add that antiseptic management, although I hope and believe it will enormously diminish mortality in the cases to which it is applicable, can never abolish the septic results of surgery. And so, on the other hand, for similar reasons, the demand (made, I think, by Mr. Holmes) to compare the statistics of eclectics and antiseptics can lead to no conclusion whatever, but only to confusion and error. The more limited inquiry which I suggest is, perhaps, more feasible and useful; and I hope, at some future time, to make some contribution to it. Meanwhile, I am not in a position to do so, because I have not myself invariably applied the rigid tests I have mentioned. I do not believe that the frequency of failure will be found to militate much against the usefulness of the antiseptic method. I feel assured (inasmuch as I know of only five cases in which I have not succeeded when I might fairly have hoped to succeed during the past six months) that the percentage of failures, taking into account certain dubious cases, is not greater than ten per cent.; and that, with more experience, I shall be able still farther to reduce it. There is nothing mysterious or difficult in the process; but, as I have said, it involves perpetual attention to minute details on the part, not only of the surgeon, but of his assistants; and a certain number of mistakes will, therefore, always occur, the probable proportion of which it would be well to ascertain both generally and for the varying sizes and kinds of wounds.

Hence arises also another interesting point of inquiry. To what extent may we class our failures under the heads avoidable and unavoidable? How much may be due to errors of manipulation? How much to other causes? We do not yet know whether, in the human subject, putrefaction may sometimes come from within. Most certainly, such a result must be exceedingly rare. But I have not myself the slightest doubt that there is great variation in the susceptibility to inoculation of different patients. We know, of course, that, according to the constitution of the patient and the character and locality of the lesion, the effects of the contact of putrescent material vary infinitely. In this empyema, we have seen much suffering result; in the excision of the mamma, none at all; and, in the abscess of the tibia, very little. But I think there is reason to believe that gross errors of management may sometimes be made with impunity; while, in other instances, the slightest flaw inevitably leads to putrescence; that, in short, the soil is sometimes so unfavourable, that many germs may fall upon it and die; while, in other cases, one will be sufficient to insure luxuriant growth of bacteria.

## CASE OF ACUTE PHOSPHORUS-POISONING.

By W. T. MARTIN, M.D., Surgeon-Major.

R. G. B., AGED 31, servant, of active and moderately temperate habits, was admitted to the Royal Victoria Hospital, Netley, at 10.30 A.M. on December 18th, 1877. He stated that he had had liver disease in India seven years previously, when serving in the 66th Regiment; and that he had been ailing for about ten days. On admission, he was very weak, anxious, and depressed; appeared drowsy, but complained of sleeplessness. No spots were observed on the skin, which, with the conjunctivæ, was of a distinct yellow tinge. The tongue was coated with blackish fur; bowels constipated; belly tympanitic; abdomen

and right hypochondrium slightly painful on pressure; area of hepatic dulness not increased (diminished, if anything); and there was no vomiting. The condition of the respiratory system was normal; pulse 88, weak; temperature in the axilla 98 deg. He had passed urine. The case being regarded as one of blood-poisoning by bile, he was ordered pills containing calomel, scammony, and colocynth, a warm bath, turpentine fomentations, and milk diet. In the afternoon, the temperature rose to 99 deg.; but was not afterwards recorded, as, when visited in the evening, he was sleeping quietly.

December 19th, 10 A.M.—He was much worse, lying on his back in a state of stupor, with eyelids closed, pupils dilated, and insensible. The skin and conjunctivæ were more deeply jaundiced; the extremities were cold and bluish, and a rash (petechial?) was noticed on the forehead. The pulse was 84, very weak and intermittent; respirations 48, without stertor; temperature 98 deg. The tongue was coated with black fur; the lips covered with sordes; the breath was offensive; the belly was more tympanitic; the bowels were still constipated, and the bladder was slightly distended with urine, which, on withdrawal, was found to be of a smoky colour.\* The patient's condition strongly reminded one of typhus. Four grains of calomel were placed on the tongue; hot turpentine fomentations were applied to the abdomen and legs; the nape of the neck and loins were freely blistered with the strong liquor ammoniæ. An enema of castor-oil, turpentine, and tincture of assafœtida brought away a considerable quantity of black pulqueous feculent matter. After a transient rally, during which he took some beef-tea and brandy, the stupor increased, and the patient died, without convulsions, at 5 P.M., having just previously vomited a quantity of black matter similar to what was afterwards found in the stomach.

The following particulars regarding the case prior to his admission to hospital have been kindly furnished by Surgeon-Major Watts.

"He applied to me on December 12th, complaining of being unable to retain anything on his stomach; that whatever he took in the way of food was at once vomited. His pulse was quiet; his tongue a little furred; and I was inclined to attribute the symptoms to the effects of spirit-drinking. I ordered him a sinapism to the epigastrium, and an effervescent mixture with hydrocyanic acid. On the 14th, he presented himself at the office, and had his medicine repeated; he still complained of vomiting after food, pain in the stomach, and of feeling altogether ill. On the morning of the 16th, I visited him in his room; he was complaining of great pain in the epigastrium, and his belly was somewhat tumid and a little tender on pressure. The vomiting, however, had subsided to a great extent, and he was able to retain food on his stomach. His pulse was a little accelerated; but there was no notable increase of temperature. On the morning of the 17th, I noticed considerable discoloration (brown to yellow tinge) of the skin; but the conjunctivæ were not yellow. The belly was tumid; tongue furred; pulse quiet. The bowels had been twice moved. He said he was better. I ordered infusion of gentian with bicarbonate of soda. In the evening, he was decidedly worse; and he complained much of thirst and insomnia. The following morning, he was moved into hospital."

A *post mortem* examination was made forty-three hours after death by Surgeon-Major Boileau, M.D., Assistant-Professor of Pathology, who has been so good as to contribute the following notes. The length of the body was sixty-six inches; the girth of the thorax thirty-five inches; weight 137 lbs. The integuments, especially those of the upper parts, were tinged yellow. There was considerable hypostatic congestion; slight rigor mortis. The pupils were dilated, and the conjunctivæ of a deep yellow. The abdomen was extremely tympanitic. There was a cicatrix on the body of the penis. The muscles were of a healthy red appearance. *Head*.—The pia mater was rather freely injected; the arachnoid presented a good deal of opacity; the brain-substance was firm and normal on section; the lateral ventricles contained a small quantity of serum. *Neck and Thorax*.—The mucous membranes of the epiglottis, larynx, trachea, and larger bronchi were of a deep purple colour. The œsophagus contained a very dark coloured tenacious fluid; its mucous membrane was pale, and presented some dark striae. The lungs were normal, except that, posteriorly, they were engorged with blood. The surface of the pericardium had an icteric tinge; its cavity contained about a drachm of fluid. The substance of the heart was fatty; its surface was pale and unhealthy looking. There were no clots in the cavities, only a small quantity of dark fluid blood in each. The endocardium of the left ventricle presented several ecchymotic patches. The valves were healthy. The weight of the heart was five thousand nine hundred and twenty grains; its bulk

\* This urine was not tested; but some drawn from the bladder after death presented the same physical characters, and was found to contain blood. After boiling and filtration, Pettenkofer's and the nitric acid tests for bile were applied, with negative results.

twenty-three cubic inches; its specific gravity 1.019. *Abdomen*.—A quantity of pale yellow clear fluid was found in the peritoneal cavity. The stomach contained a black, thick, tenacious fluid, resembling a mixture of black-lead and coffee-grounds, and with a peculiar indescribable odour, suggestive of Worcestershire sauce. The mucous membrane was of a greyish cream-colour, soft, and quite devoid of vascularity and all appearance of erosion. It was smooth and felt somewhat thick, and presented a few small ill-defined dark spots. The intestines externally appeared perfectly healthy. They contained about a pint of fluid similar to that in the stomach. The mucous membrane of the whole tract was pale, soft, and devoid of vascularity. No evidence existed of congestion or inflammation. The liver was small, and did not project below the costal cartilages; its upper surface was extensively adherent to the diaphragm, and, on removal, was seen to be much roughened. Its posterior aspect presented some yellow orange-coloured patches, and others of an ecchymotic appearance were observed in the right lobe, anteriorly and inferiorly. The whole organ felt very soft and flexible. On section, the lobular structure of the viscus was very indistinct; the colour generally was a pale brown, with ill-defined patches of yellow orange. The gall-bladder was collapsed, and contained a small quantity of pale green tenacious fluid. The dimensions of the liver were 9.7 by 2.4 by 7 inches; the weight 2.7 lbs. The microscope revealed extreme fatty transformation of the whole organ; scarcely any hepatic cell-structure was to be seen. In the square hundredth part of an inch might be counted two hundred and fifty oil-globules, varying in size from the 1-1000th to the 1-5000th of an inch in diameter. The spleen was small; its substance was firm; normal on section. The kidneys were normal in size, and the calyces of both presented purplish ecchymotic patches, exactly resembling those noticed on the liver and in the heart.

Such were the clinical and pathological features of this case, which would have passed as one of "acute atrophy of the liver" had not rumours reached the authorities, just before the *post mortem* examination was made, that B. was supposed to have taken poison. In consequence, a coroner's inquest was held, and the following particulars were elicited. B. had of late been in a dejected state of mind, owing to a want of success in a love affair; he had been seen in possession of rat-poison (phosphorus paste) on December 11th, and, on that morning, he suddenly became ill, restless, excited, and wild looking, and said "he had done it"; although, when pressed, he would not tell what was the matter. A fellow-servant, fancying he had taken poison, administered a mustard emetic; but it was not until the following day (the 12th) that medical aid was sought, and then without any hint whatever being given as to the occurrences above mentioned. The county analyst reported that, in thirteen ounces of the contents of the small intestines, he estimated the presence of 2.8 grains of phosphorus, besides which there was a small quantity in the contents of the stomach. He found, moreover, that nearly the whole of the phosphorus obtained was present in the form of phosphorus acid, which accounted for the absence of luminosity.

REMARKS.—It will be noticed that the symptoms and pathological appearances observed in this case correspond in a most striking manner with those of "acute atrophy of the liver", as detailed by Murchison in the last edition of his work. In the absence of all suspicion, inquiry was only accidentally directed into the right channel, and the real nature of the case brought to light. I am tempted to publish it on account of its rarity and importance, corroborating, as it does, Wagner's opinion, quoted by Murchison, that many of the recorded instances of acute atrophy were probably cases of acute phosphorus-poisoning.

## ON SOME POINTS IN THE CLINICAL HISTORY OF CHOREA.\*

By W. R. GOWERS, M.D.,

Assistant-Professor of Clinical Medicine at University College.

[Concluded from page 449 of last number.]

### III.—THE DISTRIBUTION OF HEMICHOREA.

HEMICHOREA is sometimes strictly unilateral in its distribution, affecting conspicuously the arm and the leg. Not unfrequently, however, the condition of the two legs is the same, when one arm only is affected.

1. The choreic movements may be confined to one arm, both legs being free from movement, although that in the arm is violent.

2. When the chorea affects considerably one arm and leg, although the other arm is quite free from movement, it will generally be found,

on close examination, that there is some degree of affection of the other leg.

3. Occasionally the affection of the other leg is as great as that of the leg of the side on which the arm is affected.

The distribution of the chorea may thus be unilateral in the arms, bilateral in the legs. No doubt the explanation is to be found in the anatomical relations which underlie the common joint action of the legs and separate use of the arms. The same thing may be occasionally noted in unilateral convulsions, in which, as in one case I have recorded (*Lancet*, Nov. 6th, 1875), the convulsions were the result of an unilateral meningeal hæmorrhage: the fits affected one arm and both legs equally, leaving the other arm free. This distribution of the spasm in hemichorea is thus quite in harmony with an unilateral pathological cause.

### IV.—THE RELATION OF CHOREA TO CONVULSIVE SEIZURES.

If chorea depend on an unstable condition of the nerve-centres, it is not surprising to find that the affection is occasionally associated with other diseases which we ascribe to a similar instability of nerve-cells, such as hysterical and epileptoid seizures of various kinds, and even genuine epilepsy. The association is probably, in some cases, that of a common origin, in imperfect development or nutrition of the nerve-centres; but, in others, it would appear as though the morbid process, constituting the one affection, entailed an instability of tissue, which resulted in the other disorder.

The following cases illustrate the association, and one or two of them are of sufficient importance to deserve detailed narration. This applies especially to the first case, in which we have the choreoid movements, when most intense, assuming a convulsive character.

CASE IX. *Many Attacks of Choreia: Mitral Constriction: During Choreia, daily attacks of Loss of Consciousness, deviation of Head, and Spasm in Limbs, tonic and choreoid.*—Alice P., aged 15, was admitted into the National Hospital for Paralysis and Epilepsy, in October 1875, with general chorea, very violent in character. She had had repeated attacks of chorea during the preceding seven years, for which she had been in several hospitals. She had a very loud and marked mitral presystolic murmur. At first, the choreic movements were greater on the left side than on the right. The attack lasted four months, and then gradually lessened, almost, but not quite, ceasing for several months; and then increased so that, in October 1876, she was readmitted. There was then much mental obtuseness; the look was dull and heavy. When she was at rest in bed, the spasm was slight; on movement, it became extreme and general. The speech was difficult. The tongue was protruded and withdrawn slowly. Almost every day after her admission, she had a peculiar convulsive seizure. One of these I saw, and several were witnessed by Dr. Sturge, then resident medical officer, who made some careful notes of their character. The following is his account of one of these attacks. "Whilst I was listening to the heart, and just after she had spoken to me, she gave a sort of groan, became flushed and somewhat cyanotic; her head was turned to the right, the left sterno-mastoid being strongly contracted, and the eyes deviated to the right. There was a good deal of general movement of the limbs, at first choreic rather than convulsive. Thinking she was in pain, I asked her what was the matter, but got no answer, and she was apparently unconscious. The movements increased, and she had some degree of opisthotonos for a short time, and the character of the movements became more convulsive. The condition lasted three or four minutes and gradually went off, leaving her in a dull heavy state, and with more choreic movement than before the fit."

In another fit, which was watched from the commencement, the head again turned to the right. There was no initial pallor of face; but the countenance became more suffused than before the fit. The right arm and leg were affected with greatly increased choreic movements, while the left arm was stretched out rigidly from the side with the fingers extended, the thumb extended and drawn under the fingers. The rigidity was cataleptic in character; for the arm remained rigid wherever it was placed. The fit lasted about two minutes, and left the patient very stupid and dull. After she came to herself, the left arm was weaker than before.

A third fit, witnessed a day or two afterwards, differed in some respects from the others, although of the same general character. She was at first apparently more or less unconscious, without any movement. This condition lasted for half a minute, and then convulsion set in. The head was drawn violently to the right; the eyes remained open, the pupils rather dilated. There was some arching of the back, and tonic spasm in both arms and hands, that in the flexors preponderating, so that the elbow, wrist, and finger-joints were all strongly flexed and the arm was drawn up almost to a level with the shoulders. After a few seconds, the right arm became affected with a sort of choreic movement, the wrist and fingers remaining flexed. The left arm became

\* Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877.

more flaccid, but remained motionless, while the right arm was affected with this movement. The legs were not specially noticed, but there was certainly not much movement in them. The jaws all the time were firmly closed. The whole condition lasted about two minutes, and she was left dull and stupid. The left arm did not seem weaker after the attack. A fortnight later, it was found that her left arm was weak, being helpless, although by great effort she could move it a little. Both legs were weak, but the left was weaker than the right.

Fits similar to these occurred daily for three weeks. Under hypodermic injection of morphia, the fits ceased, and the left arm became stronger, but the choreic movements in it were more considerable. She improved for a time, and then relapsed and remained stationary until placed on glycerine (half an ounce three times daily), which was followed by a very rapid and immediate improvement up to a certain point. Afterwards, with country air and zinc, all choreic movements ceased, and she has remained free from the disease: the mitral presystolic murmur persisting.

**CASE X. A Single Epileptic Fit, succeeded a month afterwards by Hemichorea.**—A lad aged 17 lately came under treatment for slight but characteristic hemichorea. The affection was of two months' duration, and was first discovered by objects being dropped in consequence of a "kind of catch in the hand". There was only a slight occasional twitch in the hand and on the right side of the face, but an attempt at movement was accompanied by characteristic choreic inco-ordination. The right hand was weaker than the left. (Dynamometer—right 31, left 41 kilogrammes). He had never had rheumatic fever, and there was no cardiac murmur. His mother said that about three or four years ago he had an illness, accompanied by twitchings, and occasioned by fright. Three months before the patient came under observation, and one month before the commencement of the hemichorea, he had an epileptic fit, which seemed, as far as could be ascertained, to have been general. He fell without warning, and during the fit he bit his tongue.

**CASE XI. Left-sided Fits for six months, beginning in Foot: Slight Attack of General Chorea.**—Eliza T., aged 22, had her first fit six months before she came under treatment. The catamenia had never appeared. She had had no food for two days before the first fit. It was the same in character as subsequent attacks. Each began with a sensation in the left foot; the left leg was then drawn up, the knee being flexed, with a series of jerks; and the foot drawn up over the other leg. The sensation then seemed to pass up her side to the top of the head, and then back again to her heart, where it caused a sort of pain, with which she lost consciousness and fell backwards. What happened during the further progress of the fit could not be ascertained; apparently some time elapsed before consciousness was recovered, and, on coming to herself, she invariably asked the time. Two or three such fits had occurred weekly. For a few weeks before admission, she had noticed a numb feeling in the left arm, and when holding an object the grasp would suddenly relax for a moment, and during about two weeks there had been involuntary movements in the arms. On admission, there were well marked choreic movements of the hands and head, slight but quite characteristic: spontaneous. There was very little inco-ordination on voluntary movement. There was no cardiac murmur. After her admission, the chorea gradually ceased in the course of six weeks and she had no fits, although she sometimes had a sensation, such as preceded a fit, commencing in the foot and passing up to the head. These sensations continued for some weeks after her discharge; but she had no severe fit during three months in which she continued to attend as an out-patient.

**CASE XII. Fits from Infancy, chiefly left-sided: Chorea at Eleven, chiefly affecting Left Side.**—A girl aged 16 came under treatment for epilepsy, which had existed from infancy. The first attack occurred at six months of age, during sleep. No history of rickets could be elicited. The attacks recurred at first every three months, afterwards more frequently. When eleven years of age, she had an attack of chorea, of three months' duration, succeeding an attack of some symptoms of rheumatic fever. The chorea began in the left side, and afterwards spread to the right, but throughout it was the more severe on the left side. During the chorea she had no fits, but they recommenced immediately after the cessation of the chorea. The fits were preceded by no warning; consciousness was lost. The left hand was clenched and put out, the right being kept still. The mouth was drawn towards the left. There was usually little or no jerking, but sometimes there was a good deal, and it was then confined to the left side. There was no evidence of heart-disease.

**CASE XIII. Chorea, worse in the Right Side, followed immediately by Right-sided Convulsions.**—George C., aged 12, presented himself with a history of a first attack of chorea, which had commenced six weeks before and had lasted a month, leaving, however, considerable weakness of the legs, that of the right being the greater, and some weakness

of the right arm. During the fortnight after the cessation of the chorea, he had had several right-sided convulsive attacks, with loss of consciousness. Under treatment, the fits became much less frequent, but did not cease; the muscular weakness, however, disappeared. The patient had no cardiac murmur, but the action of the heart was irregular.

**CASE XIV. Chorea, followed by Fits, beginning in Left Foot; Mitral Constriction: Subsequently an Attack of Mania.**—Kate B., aged 30, single, was admitted into the Hospital for Paralysis and Epilepsy, in January 1872, on account of convulsive seizures. A brother had died, aged 40, with what was probably general paralysis of the insane. A sister had an attack of chorea, and died four or five weeks afterwards from heart-disease. No relations had suffered from rheumatic fever. The patient herself had never suffered from rheumatic or scarlet fever. At thirteen years of age, she had a severe attack of chorea, which came on gradually without assignable cause, and lasted nine months. She believed that it affected both sides equally. Six months after the chorea, she had a fit; a second fit, three months after the first; and they had recurred at intervals of two or three months. The first and succeeding attacks were described by her as being of the same character. Each began with a sensation in the great toe of the left foot; this did not pass to the other toes, but ascended up the foot and leg to the trunk; as it was passing up the trunk, it commenced in the left forefinger. It did not go to the other fingers, but passed up the arm, and thence to the left side of the tongue, in which she had a sensation of tinglings. The sensation was accompanied by some movement of the part: a slow drawing up. She then lost consciousness, and could give no account of the subsequent phenomena. Her tongue, however, was often bitten, so it might be assumed there was severe clonic spasm. Sometimes she had a similar sensation in the right hand, passing up the arm to the side of the tongue, but never to the leg; and this sensation was never followed by loss of consciousness or any further convulsive manifestation. When she had a fit commencing in the left foot, the sensation never passed to the right side. Whilst in the hospital, she had several epileptiform fits, of which no detailed account could be obtained, and also several peculiar attacks of co-ordinated spasm, one or two of which I witnessed. They began with the same sensation as above described, and, when consciousness was lost, the eyes were turned up and to the left; the arms were not affected, but the legs were rigid and drawn up, and she tended to turn on to her back. Subsequently, the legs were drawn up and then pushed down regularly, so that, if she were on the floor, she would work, head foremost, from one side of the room to the other. The sensation preceding these attacks was slighter than that which preceded the severe seizures, and was accompanied by an unpleasant feeling at the back of the head and at the heart. The heart's apex was outside the left nipple, the impulse heaving and diffused, and at the apex was a loud rough, rather long, presystolic murmur, terminated by the first sound. The maximum point was the nipple-line; it was conducted in and out; heard on the mid axilla, but not at the angle of the scapula, where the heart-sounds were clear. The second sound was reduplicated; a brief interval occurred after the second part of the second sound, and before the presystolic murmur. The fits continued in spite of treatment, although slighter.

Nine months later, while taking ten minims of tincture of digitalis three times a day, her pulse sank to 48, and some mental symptoms came on. On omitting the digitalis, the pulse rose in twenty-four hours to 72, but the mental symptoms continued. She fancied persons were in the room speaking to her and she answered them, and asserted that she was the Holy Ghost; and under that delusion manifested some tendency to violence, so that it was necessary to send her to an asylum. She recovered after some months, and has since continued in nearly the same state, with occasional fits and the same evidence of organic heart-disease. The presystolic murmur, however, has been variable; sometimes not to be heard, sometimes distinct, as is not uncommon in cases of mitral constriction. There has been at no time albumen in the urine.

**CASE XV. Severe General Chorea: Convulsive Seizures, commencing two years after the Cessation of the Chorea.**—The patient was a married woman, thirty-two years of age. As far as could be ascertained, there was no family predisposition to nervous disease. She had had good health in early life. At nineteen years of age, she had an attack of chorea, occasioned by a fright, and sufficiently severe to cause her admission into a general hospital. The attack was a long one, lasting two years. Two years after the cessation of the chorea, and after some trouble, she had her first convulsive seizure. No fuller account of it could be obtained than that she was stiff and screamed, and bit her tongue. The fits continued from that time; and she said that of late, when a fit was coming on, objects looked strange to her and she saw sparks before her eyes, and sometimes an appearance as of smoke or

of "all kinds of colours". She was admitted into the hospital, and there had attacks in which, with apparent loss of consciousness, there was general tonic rigidity, but no clonic convulsion. Some of the attacks lasted several hours; others were shorter in duration, and seemed to be excited by a severe cough which troubled her.

CASE XVI. *Chorea; followed some years later by Hystero-epileptic Seizures.*—Ada S., when five years of age, was under treatment, at the Hospital for Paralysis and Epilepsy, for a well marked attack of chorea, from which she recovered, apparently completely. Three years after the chorea, when nine years of age, she became subject to "fits". These attacks commenced with jerking of the head and loss of power of speech for several hours. She was able during this time to hear quite well, but was unable to speak. Then she would suddenly lose consciousness, the jaws "champed", a noise was made in the throat, and "foam" collected in the mouth, almost choking her. There was no general convulsion. After the attack, she generally slept for some time. At one time, these attacks recurred regularly every three weeks. Under treatment, the fits became less frequent and slighter, but there was much jerking of the head after waking in the morning, lasting an hour or more. In the slighter fits she would suddenly fall, be unable to speak for a moment, and rigid; then she would scream, clutch with her hands, and foam at the mouth. There was no cardiac murmur.

CASE XVII. *Chorea in Early Life: Epilepsy in Middle Life.*—John L., aged 50. No history of family neuroses. At ten years of age, he had an attack of chorea; but he had no subsequent illness until forty years of age, when he had a fit, and since that time has had four or five fits a year, always occurring at night during sleep. He does not wake before the fit, but passes into severe clonic spasm, in which he bites his tongue. His heart is healthy to physical examination, but intermits occasionally, not regularly.

CASE XVIII. *Chorea in Early Life: Epilepsy Late in Life.*—A man aged 58 came under treatment for epilepsy of three years' duration. His family history was bad. His father had been intemperate, and his brother died from chronic alcoholic delirium. At sixteen years of age, he had an attack of chorea, of which he could only remember that it was a bad attack and affected both sides. When thirty-two, he had an attack of rheumatic fever, which had left no obvious valvular disease of heart. The commencement of the fits was attributed to insufficient food. They occurred frequently, three or four a week, both day and night, during waking and sleeping, without warning. Consciousness was lost in them, and his tongue was bitten.

These cases illustrate the frequent association of chorea and epilepsy, and they illustrate also several of the ways in which that association is produced. The possibility of a close connection between the two forms of spasmodic disorder is shown in the first case, in which paroxysmal convulsive seizures were part of a severe attack of chorea. In them, although the spasm was in part that of chorea, so intense as to assume a convulsive character, there was also loss of consciousness, and spasm of a tonic character preceding and accompanying the choreoid convulsion. The significance of this case is that the convulsion must be ascribed to the same morbid process as that which was the cause of the chorea.

In the next three cases, Cases X, XI, and XII, we have instances of chorea succeeding epileptoid seizures. In one, a single general convulsion occurred a month before hemichorea; in the other, unilateral fits for six months were succeeded by an attack of general chorea. In these two cases, then, there was no relation to be traced between the distribution of the chorea and that of the convulsion. In Case XII, however, epileptic attacks occurred during almost the whole of life, and were interrupted by an attack of chorea. Both chorea and convulsions agreed in their distribution, and were most severe on the left side. No significance can be attached to the cessation of the fits during the chorea, since it is common for attacks to cease during the course of any acute disease.

In the remaining cases, convulsive attacks succeeded chorea. In Case XIII, chorea, worse on the right side, was succeeded immediately by right-sided convulsions; and it is, therefore, highly probable that the two were the expression of the same morbid change. In Case XIV, permanent epilepsy of marked character succeeded, at intervals of six months, an attack of chorea; and in Case XV, convulsive seizures commenced two years after the termination of an attack of general chorea. In Case XVI, a similar, although rather more distant relationship, was to be observed; while in the last two cases, the interval between the chorea and the epilepsy was so long that probably the only significance is that of a common predisposition.

Several of these cases presented evidence of organic heart-disease; and it may be urged that in this there is a common condition, which

may be a cause of the two sets of symptoms. Heart-disease is common in chorea, and I have found that it is sufficiently frequent in epilepsy to make it probable that there is a causal connection between the two conditions. But such an explanation leaves unexplained the several cases in which no heart-disease could be discovered, and the remarkable association in several of the cases between the distribution of the chorea and the convulsive seizures, which point unmistakably to the origin of the two diseases in a common pathological state of the nerve-centres.

## TWO UNCOMMON FORMS OF DISLOCATION.\*

By A. W. MAYO ROBSON, M.R.C.S. & L.R.C.P. Lond.,

Demonstrator of Anatomy at the Leeds School of Medicine.

Of the two cases I am about to bring before your notice this evening, one is a dislocation of the jaw occurring during an attack of hysteria; the other is a dislocation of the sternal end of the clavicle upwards. The first is interesting on account of its cause; the second, on account of the rarity of the event.

I was called to see a woman aged 30, said to be in a fit. On arriving at the house, I found her in an hysterical attack, and ascertained that she had received news of a severe family trouble a few hours previously. A curious symptom in the case was, that she violently worked the jaw, and would persist in doing so despite being sharply spoken to and treated freely with cold water. Whilst I was observing her, the jaw suddenly became fixed widely open and displaced obliquely towards the right side. She instantly began to scream violently, and applied her hand to the injured part. I need scarcely say that the hysteria vanished as if by magic. I replaced the jaw in the usual manner, and applied a four-tailed bandage. After being put to bed, she had a return of the paroxysms, and again worked the jaw; but this time the bandage prevented displacement. The next day, beyond a considerable degree of stiffness, nothing abnormal was found. I then ascertained that she had never had dislocation of the jaw on any previous occasion. My reason for recording the case is, that I find no mention made of any similar one either in Hamilton on *Fractures and Dislocations* or in Holmes's, Erichsen's, or Bryant's works on surgery.

The history of the second case is as follows. I was called on September 27th, 1877, to see a grammar-school boy aged 15; the messenger telling me that he had put his shoulder out, having fallen undermost in a scrimmage at football. On arrival, I found him leaning towards the left side and supporting that arm with his right hand, any change of position giving great pain. On stripping the chest, the first sign that attracted my attention was a marked flattening of the left infraclavicular region. I then noticed a depression of the same shoulder; a very distinct prominence in front of the trachea just above the sternum; an absence of the natural projection of the left sterno-clavicular articulation, its place being taken by a depression in which could be felt the empty sternal socket. The tendon of the left sternomastoid was stretched tensely like the string of a bow, and the distance between the shoulder-tip and the middle line was an inch less on the affected side than on the sound one. There was no dyspnoea, and an entire absence of crepitus. My diagnosis was dislocation of the sternal end of the clavicle upwards, as the only accidents which might have simulated it were separation of the epiphysis and fracture; the latter being negatived by the absence of crepitus, and the former by the fact that ossification does not take place in the epiphysis till the eighteenth or twentieth year. Reduction was easily effected by drawing the shoulders backwards and raising the arm. I tied a handkerchief round each arm near the shoulder, and looped them together firmly behind; placed a pad in the axilla; pressed the elbow inwards by means of a bandage round the chest, enclosing the arm; and supported the elbow and forearm in a sling; after which the symmetrical appearance of the chest returned. In the after-treatment, there was a great tendency for the sternal end of the clavicle to slip upwards, as the boy, being unusually active, always contrived to romp about and loosen the bandages as soon as his attendant's back was turned. Although the appliances were continued for three weeks, and a figure-of-eight bandage for a fortnight longer, yet at the end of that time the sternal end of the clavicle remained about half an inch above its usual level; but the functions of the limb seemed to be in no way impaired. The only cases I can find on record of a similar nature are four quoted by Malgaigne, two by Bryant, one by Dr. Rochester of Buffalo, and one by Hamilton.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN AND IRELAND.

#### CLAPTON IDIOT ASYLUM.

CASES UNDER THE CARE OF DR. FLETCHER BEACH.

*Cases of Congenital Idiocy.\**—A boy, aged 13, is both blind and deaf; he is very thin and anæsthetic; he is not epileptic, and presents no permanent muscular contractions. Automatic movements of the head and neck are almost constant, the head being bent over to each shoulder alternately. These cases are usually of very low type. Many similar cases have come under observation in this asylum, and some have improved under the method of training adopted; the present case, however, appears perfectly incapable of any improvement.

Another boy, who is almost deaf, presents in a marked degree the V-shaped high vaulted palate, which was pointed out by Dr. Langdon Down as commonly met with in cases of congenital idiocy. His speech is somewhat indistinct, but he can read and write well, can add up a few numbers, and knows all the colours. He works as a shoemaker, and has made fair progress. A girl, a congenital idiot, presents marked signs of congenital syphilis; she is almost blind, as the result of iritis and interstitial keratitis; she is almost completely deaf, and the nasal bones are destroyed; the teeth, however, do not present the characteristic shape and markings. This is the only case, among several hundred examples of idiots that have come under observation in this asylum, where distinct signs of inherited syphilis have been found. Experience shows that inherited syphilis is but rarely met with in idiots.

*Diagnosis of Idiocy in Early Life.*—Dr. Beach remarked that the infant idiot is unable in many cases to support the head, which hangs back in the mother's arms; there is inability of the spine to support the body; there are muscular flaccidity, and difficulty in swallowing the milk drawn from the breast; inability to notice objects, and to follow them with the eyes if they move; no notice is taken of sounds, and the child is voiceless. Later on, we compare the child's mental and physical condition with that of other children of the same age. We notice whether the fontanelles are closed; whether the head is too large, too small, or deformed; whether the palate is highly arched (a V-shaped palate, as before mentioned, being a characteristic of congenital idiocy); whether there is ability or not to grasp objects with the hands, idiots of low type being unable to do so. In these cases there will be found, too, a flow of saliva from the mouth; the fingers are flaccid and moistened with saliva; there is inability to co-ordinate the muscles; feebleness of circulation is evidenced by cold extremities; often there are epilepsy and paralysis. In cases of a higher type, although some of these points will be absent, yet the simplest rudiments of knowledge will be unattainable in the ordinary way. These children are banded about from school to school, ultimately, if fortunate enough, finding a home in an idiot asylum.

*Hydrocephalic Idiocy.*—A fairly intelligent boy, aged 16, is the subject of chronic hydrocephalus. The head is manifestly too large, its circumference is twenty-five inches and a half; the skull is completely ossified, but the position of the anterior fontanelle is evident. The head is less globular than in infantile cases of hydrocephalus, but is enlarged in all its diameters, and is quite devoid of sphericity; there is marked increase of the distance between the eyes. His circulation is very feeble, as evidenced by blueness of the extremities and dusky skin of the countenance. He has no power for any industrial occupation. In school he reads words of three letters, but cannot write; he seems to have difficulty in holding the pen; he adds up to twenty, knows all the colours, and squares and oblongs.

*Hypertrophic Idiocy.*—A boy aged 9 presents the somewhat rare condition of so-called "hypertrophy of the brain". He is an epileptic idiot; he is able to walk, but his gait is tottering. There is a marked prominence of the central part of each half of the frontal bone; on the right side this bulging is continued round to the fronto-temporal suture, on the left side it is less marked. The general line of the forehead is somewhat flat, thus markedly differing from the rounded temples usually met with in hydrocephalus; ossification of the skull is complete, and

no mark is left indicating the site of the anterior fontanelle. The general contour of the skull is symmetrical, the palate is vaulted, and the circulation is very feeble. Mentally, he is very dull; this appears to be due to his frequent epileptic fits. In a similar case, where necropsy proved the diagnosis, the intellect was fair, but there was no epilepsy. In the school, he has made very little progress; he knows only two letters and cannot write; he knows all the colours. Contrasting the hydrocephalic case with that of hypertrophy, it was pointed out that, in the former, there is bulging outwards of the temples, which is absent in the case of hypertrophy; in hydrocephalus, too, the distance between the eyes is increased. In cases of hypertrophy, there are prominences on the forehead above the superciliary ridges, and the circumference of the head does not increase from the base of the skull upwards. In a case of hypertrophy of the brain, in a boy aged 16, the encephalon weighed sixty-two ounces, the white matter was much increased in amount, and, on microscopical examination, Dr. Beach found an uniform granular appearance, large numbers of leucocytes, which had evidently escaped from the vessels, these being very much more numerous than in the normal brain.

*Microcephalic Idiocy.*—According to the definition laid down by Dr. Ireland, all cases in which the head measures less than seventeen inches in circumference should be considered microcephalic. In a case under observation, the circumference of the head measures sixteen and a half inches, the head is very narrow from ear to ear, and prognathism is well marked (*i.e.*, the forehead is shaped like the ape's; the facial plane has a decided slope backwards, instead of being vertical as in the normal head). There is no patency of the fontanelles and the sutures are closed. There is permanent contraction of the limbs, so that the child cannot stand or use his arms; the contraction is a permanent flexion, and is increased by any attempt at passive movement. He makes his wants known, and can recognise those around him; the case appears capable of some improvement.

A second case is that of a child aged  $3\frac{1}{2}$ , the circumference of the head measuring fourteen inches and a half. The head is in every respect very small; the forehead is extremely narrow, with a considerable slope upwards and backwards; the sutures are closed, and there is no patency of the fontanelles. The right arm is permanently contracted, and there is much muscular rigidity in all the body. The child cannot stand, and leads a purely vegetative life. The eyes frequently lose their parallelism, each eye moving separately; there is no permanent strabismus; the optic nerves of both eyes are atrophied.

Such cases may be diagnosed at the time of birth or soon afterwards, by comparing the head with that of a healthy child of the same age. The causation of this condition is somewhat obscure: by some it is supposed that the condition is due to premature ossification of the skull, hindering the growth of the brain. Dr. Beach has found some cases of microcephalic idiocy capable of much improvement, the amount of possible improvement being limited no doubt by the size and quality of the brain. In the Lancaster Idiot Asylum, there is a microcephalic idiot who is able to articulate a few monosyllabic words, can match colours, makes attempts at writing on a slate, and joins in the drilling exercises of the children.

*Cretinism: Sporadic Form.*—A boy aged 11 presents cretinism in a well marked form. He is of very stunted growth, being only thirty-three inches in height; his belly is very large and prominent, due principally to the development of subcutaneous fat; and the lumbar spine is arched forward, so as to preserve equilibrium in standing. His skin is mottled, of a dirty-brownish colour, and very harsh; his hands and feet are large, out of all proportion to his body. He can walk and talk, but his mental state is very passive; he is clean in his habits. His head measures nineteen inches and a half in circumference, and is flattened at the top; his nose is pug-shaped and flattened; the distance between the eyes is exaggerated; his lips are thick, and the bony palate is very flat. His neck appears short and very fat; there is absence of the thyroid gland, the thyroid cartilage and trachea being plainly felt beneath the skin. On each side of the trachea there is an egg-shaped swelling, extending backwards in the posterior triangles of the neck.

On the subject of cretinism, Dr. Beach remarked that the cause of this condition as it occurs in England is obscure. In some cases, there has been marked intemperance on the part of the father, but this is not universally the case. In three cases, in which the brain was examined by Dr. Beach, there was found to be coarseness of the convolutions, the cortical matter was thicker than normal, the nerve-cells were surrounded by larger spaces than normal, and in some no communication could be traced between the pyramidal corpuscles. The brain-structure, in fact, was very low in type, somewhat resembling that of certain of the lower animals.

In endemic cretinism, there is nearly always a goitre, and occa-

\* Under this heading are included cases of microcephalic and hydrocephalic idiocy, cretins, etc.

sionally the same is seen in sporadic cretinism, but it is rare; and in those cases which, up to the present time, have been observed, the absence of the thyroid gland and the presence of pigeon-shaped fatty swellings in the posterior triangles of the neck have been almost universally observed. Writers on endemic cretinism have mentioned several causes, among which vitiated atmosphere, bad ventilation, want of sunlight, insufficient food, and excess of lime in the water may be noticed. Professor Virchow says that the primary defect is a premature synostosis of the two parts of the sphenoid bone together and with the basilar process.

**Epilepsy in Idiots.**—Epilepsy is of extremely common occurrence among the patients, and often presents many curious phenomena. A boy aged 12 is liable to sudden seizures as follows. He is conscious when an attack is coming on; he says he feels poorly, and complains of a pain in his head; he then becomes unconscious, jumps out of bed with a loud cry, wanders about the ward in a purposeless manner, with jactitation of his arms; he then places both hands upon the abdomen and rubs it violently. The whole is over within one minute. After the fit, he turns very pale, but there is no general convulsion of the limbs. After an attack, he shows strong sensual propensities.

An idiot of low type, now aged 11, has frequently had as many as twenty fits in a day. His intellect has gradually deteriorated, so that now his speech is limited to the words "stick" and "toss".

**Paralysis following Epilepsy in an Idiot.**—A boy, a congenital idiot, was able to run about till three months ago; then, without known cause, a series of strong epileptic convulsions occurred on and off for three days. This left him powerless in the left arm and leg, but he soon partially recovered. Three days ago, a strong convulsion occurred, and left him in his present condition. He can just walk with help in a tottering manner. His left arm is practically useless, and is the seat of constant spasmodic action of the flexors. On attempting to take hold of an object, he brings his arm towards it with a series of jerks, and often misses the object as if he did not know exactly where it was; but, after several unsuccessful efforts, he gets his hand to the object and seizes it. There is general trembling of the body, and his trunk leans over to the left side; there is also marked lateral oscillation of the head.

Children who have lost their mental powers, in consequence of epilepsy, are often found to improve under medical and physical treatment. In some cases, improvement follows to such an extent as to enable them to work in the house, and in other instances even to gain their own livelihood in the world. The principles of treatment adopted are: an unstimulating diet, a course of gymnastics, warm clothing; and, medically, bromide of potassium in doses of fifteen to thirty grains three times a day, according to the circumstances of the case and the age of the child. As the fits diminish in number and severity, the dose of bromide is diminished, but is still continued in diminished doses for months or years.

**Imbeciles.**—The term imbecility is generally used to denote a less degree of mental incapacity than that which is found in idiocy. It would be well to abolish the term idiocy and to use the term imbecility only, cases being divided primarily into congenital and acquired.

A girl aged 14 is the child of an excitable and intemperate father. A maternal uncle is epileptic. She had a few fits at the time of dentition, but appeared well till eight years of age, when she fell on her head from a swing. Epileptic fits followed, and continued for six months, when she was admitted into the asylum, now three years ago. Much mental impairment resulted, so that on admission she was sullen, obstinate, and totally ignorant. At the present time, she can read, write, and act as a housemaid; the fits ceased after two months of treatment.

Another case is that of a boy aged 16, whose father is intemperate and mother consumptive. He appeared healthy till six years of age, when he was kicked in the back; fits followed for twelve months. When admitted, he was very dull and slow. The fits have now left him. He can read and write, and is an excellent shoemaker.

J. M., aged 16, with a strong history of consumption on the mother's side, whose mother, brothers, and sisters are very "nervous", was born perfectly right. As a boy, he was somewhat soft-hearted, with a tendency to cry when spoken to harshly. As he grew up, he was employed as a page in several places. In the last, he was much teased by his fellow-servants, who were fond of playing practical jokes upon him. One of these very much frightened him, and as a result he became lost and dazed, his intellect being much impaired. When admitted, three years ago, he was very stupid and knew absolutely nothing. He has to a great extent recovered, though he is subject every now and then to recurrences of his former state. On these occasions, he will remain for a week together quite apathetic and unable to do his work as a tailor, a trade which he has learnt since his residence in the asylum. Gradually recovering, he resumes his work as before. He has made good

progress in the school, but, though he plays cricket and joins in games with the other boys, he does not enter into them with as much zest and spirit as they do. Should these recurrent attacks cease, there is every probability of his earning his livelihood in the world.

Dr. Beach remarked that, in the causation of idiocy, heredity plays a great part. Idiots are frequently born in families in whom there is a neurotic tendency, evidenced by insanity, epilepsy, etc., in the parents, brothers, or sisters of the patient. Consanguineous marriages and syphilis do not play so great a part as might be supposed. Shocks, frights, and anxiety to the mother during pregnancy, are very common causes. Intemperance of the parents indirectly plays a great part in its production, the result being a child with a weak brain, easily upset by slight causes. Some children are born with all their faculties, but, as the result of blows or falls on the head, fevers, starvation, etc., become imbeciles. In these a neurotic history is often met with; the tendency, however, not being sufficiently strong to produce a congenital idiot. The pathology of idiocy has not yet received much attention, but it is being investigated at Clapton.

**Treatment.**—A combination of medical, physical, moral, and intellectual treatment must be employed, the basis of all being medical. Herbert Spencer, in his work on *Education*, dilates on the last three; but the medical, in the cases of idiots and imbeciles, is the most important of all. The body must be kept in as perfect a state of health as possible; the diet should be liberal; the apartments in which the patient lives well ventilated, and the residence in a healthy situation. As much out-door exercise as possible should be obtained, and any ailment from which the patient may suffer should receive immediate attention. The physical treatment should commence with the simplest movements possible; and, to overcome the want of co-ordinating power, more complicated movements being afterwards gone through with the aid of music. His moral education must not be neglected. He has to learn that to do right will meet with a reward, to do wrong with punishment, which again is to be effected by moral means. The basis of the intellectual treatment must be objective. The concrete, not the abstract, must be taught. The patient must learn to recognise the form and qualities of objects by touch; colour, size, and shape by sight; the varieties of sound which impinge upon the ear, and his taste and smell, must be educated. He must be taught to dress and undress himself; to use his spoon, knife, and fork; and his speech must be improved by a course of tongue gymnastics, his well known faculty of imitation being utilised to the fullest extent. He should be taught the value of money, and to buy and sell. He should learn carpentering, gardening, or farming operations, tailoring or shoemaking, according to his class in life, care being taken that plenty of amusement is provided.

## LONDON HOSPITAL.

TRAUMATIC ABSCESS OF THE LIVER: PUNCTURE: IRRIGATION OF THE ABSCESS-CAVITY: RECOVERY: REMARKS.

(Under the care of Dr. STEPHEN MACKENZIE.)

S. S., AGED 39, was admitted on August 4th, 1876. The patient had led a seafaring life for twenty-six years, voyaging mostly to the East and West Indies and China. He had never suffered from the effects of heat, and had never had dysentery, ague, or fever. In fact, he had always enjoyed exceedingly good health, and had had no illness until the present. About the middle of June 1876, he had a fall down the vessel's hold, a distance of about twenty-five feet. It would appear that he struck his chest in the fall, and, when he was picked up, he had pain and soreness over the right side of the chest. He also injured his left leg. In a week's time, however, he was at work again, and remained in apparently good health until a week previous to admission, when, on rising after sleeping, he felt a sharp pain at the lower margin of his right ribs. This pain caused him to look at the part, when he noticed a swelling, which was then very slight, but which gradually increased until admission. He had no rigor from the time of his injury up to the date of admission.

On admission, a globular fluctuating tumour, about the size of an orange, was found in the right hypochondrium. A small trocar and cannula were introduced into the swelling, and gave exit to a little thick healthy pus. An incision was then made into the tumour, and a little more pus came away.

The patient was transferred to my care on August 12th, when I made the following note:—"A bulging tumour in the right hypochondrium, with an incision at its most prominent point, which is immediately below the margin of the ribs. The tumour is dull on percussion, and continuous with the liver-dulness. The upper border of the latter reaches to the lower border of the fifth rib above, to the eighth rib in

the axilla, and to the ninth rib posteriorly. The lower limit cannot be accurately defined, owing to tenderness in this situation; but it appears from palpation to reach some little distance below the margin of the ribs. The tenderness extends to the ensiform cartilage, where the right lobe of the liver appears to end. A large vein is ramifying over the right side of the chest. No abnormal signs in the chest; no distension of the abdomen; no ascites; no enlargement of the spleen; no jaundice; no œdema of the feet. The patient is a very intelligent healthy looking man with dark sunburnt skin."

August 21st.—There had been a pretty free discharge of "laudable" pus since the last note; on one or two occasions, small lumps of greenish colour had come away. The wound was washed out morning and evening with tincture of iodine freely diluted. He had at first pain and tenderness over the liver, and a pain or stitch caught him on this side when he took a deep breath. These had now disappeared. He had complained of headaches, and had had nausea, but no vomiting. His temperature to-day (morning) was 101.5 deg. Fahr.; but, on the morning of the 18th, it was 104 deg. His tongue was large, coated, and slightly indented by the teeth. His appetite had not been good. His bowels had not acted since the evening of the 18th; then his motions were black and fluid.

September 4th.—There was a free discharge from the wound. The patient shivered and his teeth chattered last night at ten o'clock. His temperature rose to 100.5 deg. (it had been between 99 and 100 deg. the two preceding nights). At twelve o'clock, he began to sweat, and, after this, he felt much relieved. No changes could be detected in the thorax; no cough; no expectoration.

September 13th.—He had shivering again last night, but no chattering of the teeth. He slept pretty well. *Râles* were heard over the lung bordering on the liver. He had no pain. There was free discharge from the wound. The temperature was fluctuating, with evening exacerbations averaging 102.5 deg.; morning remissions to about 99 deg.

September 16th.—He had no more shivering. He complained to-day of great pain at the lower part of the right chest, in the vicinity of the wound; it was most severe on deep inspiration.

October 4th.—There was a free discharge every day from the wound. His appetite was pretty good. During the last few days, he had complained of severe shooting pain passing from the scrobiculus cordis, round the right side to the back. There was no friction-sound or other symptom of pleurisy; but *râles* were to be heard in the lung, at the upper hepatic border.

October 9th.—There was soft diffused swelling opposite the lower ribs, the central point of which was about five inches external to the aperture in the hypochondrium. The swelling was not circumscribed, and there was no fluctuation to be detected; but the skin over it was slightly red. He had great pain yesterday, which, he said, almost prevented him from breathing. The large vein in the axilla previously noted was more prominent.

October 20th.—There was free discharge from the wound. He vomited frequently during the night. On about the 4th instant, blood was noticed in his urine. There was no assignable cause for it. He had no œdema or pain in the loins. His temperature about this time was, perhaps irregularly, increased. The blood had now disappeared, without more marked symptoms than ushered in its advent.

November 3rd.—The patient looked and expressed himself as much better. His temperature had been normal for a fortnight. There was still a small sinus discharging a little pus daily. The abscess-cavity was very small; only a drachm or so of fluid could be injected. There was no increase of hepatic dulness, but there was still a slight tenderness over the lower ribs.

December 8th.—He was up and about. He had no pain now, except a little after tea; his dinner did not cause him any pain. Hepatic dulness was bounded above by the sixth rib in the right mammary line, by the eighth rib in the axilla, by the tenth rib in the dorsal region. Below, the dulness did not extend below the lower margin of the ribs. There was still slight tenderness in the right hypochondrium. He was discharged.

REMARKS.—Traumatic abscess of the liver is very rare, the immunity of the liver from injury being generally attributed to the effectual protection afforded by the ribs. Maclean only mentions one case within his own experience; Murchison does not mention a single case under his own observation; Budd quotes a case of Andral's (the only one out of sixty-two collected cases of hepatic abscess), but does not record a case of his own. The treatment was rational and effective. The abscess was first emptied, and its sac kept antiseptic and made to contract by irrigating the cavity with diluted iodine solution. The patient had a narrow escape, however. He had an attack of diaphragmatic pleurisy, and, later, mild septicæmia.

## WEST LONDON HOSPITAL.

### IMPASSABLE TRAUMATIC STRICTURE OF THE URETHRA; BOUTONNIÈRE OPERATION; RECOVERY.

(Under the care of Mr. TEEVAN.)

DAVID B., a ship's steward aged 50, was admitted into the hospital April 9th, 1877. From notes taken by Mr. R. Cumming, the House Surgeon, it appeared that, five years ago, the patient was kicked in the perineum by a man wearing heavy sea-boots. He did not experience any pain at the time, nor was there any bleeding; but two months afterwards, a hard lump, about the size of a pigeon's egg, came in the perineum. The stream of urine became twisted, and passed with difficulty, and he frequently had shivering fits. The lump did not go away; and two months later, both testicles began to swell, accompanied by much pain. He then came to England, and for four months remained in bed, poulticing the parts with much benefit. Shortly afterwards, he put himself under Mr. Teevan's care. At first, no instrument could be passed; but after a time, a small one was introduced, and the stricture gradually dilated to No. 15 (French), when he left for a voyage to the West Indies. He remained so well, that on his return, he immediately went for another voyage to the previous destination. On his way back, he experienced much pain and difficulty in micturating, and passed clots of blood. He, however, started on a third voyage; and during it the lump in the perineum broke, discharged, and healed up again. This happened three or four times; and on each occasion, urine escaped from the opening.

When the patient was admitted, he was in fair health but much depressed. He could only pass his urine in drops by dint of much straining. In the perineum, there was a mass of induration of stony hardness, as large as a hen's egg. The urine contained some phosphates, but no albumen or sugar, and its specific gravity was 1025. Considering that no instrument, soft or metal, could be passed, and that the stricture was of traumatic origin, Mr. Teevan determined to perform the boutonnière operation.

On April 17th, at 3 P.M., the patient was put under the influence of ether by Mr. T. G. Alderton, and Mr. Teevan tried to pass the smallest silver catheter into the bladder, but failed. He then introduced a full-sized straight staff, with a groove in it, as far as it would go, and opened the urethra on its point. An attempt was now made to insinuate different bougies through the stricture, and one was at last passed apparently into the bladder. Its position was then demonstrated by sliding a very fine metal catheter, open at both ends, over it, and withdrawing some urine. The stricture was now divided by running a tenotome along the groove in the metal tube, and the vesical half of the elastic catheter, described in the number for September 30th, 1876, of the BRITISH MEDICAL JOURNAL, having been slipped over the metal tube into the bladder, the penile half was passed down into the wound and screwed on to the vesical portion. The patency of the urethra having been demonstrated, the catheter was withdrawn. At 6 P.M. the same day, there was some bleeding, which was stopped by the application of ice. Temperature 99.4 deg. Two hours later, the patient was sick twice and had a little shivering.

April 18th, 10 A.M.—Had a bad night. The urine passed both ways. The tongue was covered with a dirty yellow fur. Temperature 99.8 deg. At 12.30 P.M., he had a rigor. Pulse 140; temperature 101.6 deg.

April 19th.—Had a bad night, and was feeling low.

April 20th.—Had a good night, and felt much better. Temperature 98.4 deg. No. 18 was passed from the wound into the bladder.

April 24th.—Had slept well. All urine came by the wound, which looked healthy. No. 15 was introduced.

May 1st.—He was going on well. A No. 17 catheter was passed; the wound was healing. The treatment adopted was to introduce a catheter twice a week; and by June 1st, the wound was so reduced in size that the patient was taught to draw off all his urine with a No. 16 catheter. He was able to do so efficiently, and the wound was nearly healed on June 30th, when he left the hospital at his own request. He paid one visit as an out-patient, and then discontinued his attendance. When he left, his urine was clear, acid, free from albumen, and its specific gravity 1020.

Mr. Teevan observed that traumatic strictures differed so greatly in character from organic ones, that they might be well placed in a separate category by themselves. The treatment which might be thoroughly efficient in the latter instances would very likely prove utterly futile in the former, and hence it was that traumatic strictures so often called for an operation. He had so modified the performance of the "boutonnière", that its execution was rendered easier, and the surgeon was enabled to determine with accuracy where his deep cut

should be. The operation was indicated in cases of impassable stricture, retention from the same, and in extravasation. Its great recommendation was that, by it, cause and effect were remedied at one and the same time, which was more than could be said of such temporary expedients as puncturing the bladder. When the wound was nearly healed, it was well to hasten its final closure by teaching the patient how to draw off all his urine, so that the chance of any fistula being left was reduced to a minimum. In accordance with his usual practice, he had left no catheter in the bladder after the operation.

#### NORTHUMBERLAND COUNTY ASYLUM.

##### ANOMALOUS CASE OF PNEUMONIA.

(Under the care of Dr. T. W. McDOWELL.)

J. S. WAS admitted on March 12th, 1873. At that time, he was sixty years of age, and had been insane ten years. He had resided with his relatives; but, as he became somewhat violent and troublesome, he was sent to the asylum. It was stated that during the first six years of his illness he had epileptic fits. His uncle had been insane.

On admission, he was a stoutly made man, fairly muscular, with grey hair, slightly bald, hazel eyes with well-marked arcus senilis, large nose, and intelligent facial expression. The teeth were dark and somewhat irregular. The head measured  $22\frac{1}{4}$  inches in circumference,  $13\frac{3}{4}$  from ear to ear, and  $13\frac{1}{2}$  from occiput to root of nose. He appeared to be in good general health. The heart-sounds were normal; the lungs were healthy; the appetite was good; the bowels were regular. The urine was rather pale, slightly acid, of specific gravity 1015; no albumen. He was in a state of chronic mania. As a rule, he was very quiet; paced up and down the ward as if absorbed in thought; seldom spoke except when asked a question, when he answered shortly and abruptly, and passed on. At other times, he was somewhat more communicative, and said that ever since he came here his tormentors had not troubled him.

No improvement occurred in his mental condition. He continued deluded about people tormenting him at night, but on most subjects he was quite rational. He seldom did any work, but generally occupied his time in reading the newspapers, chatting with his neighbours, and so on. During his residence here, his general bodily health appeared excellent. On one or two occasions, it is noted that he was confined to bed on account of influenza and slight bronchial catarrh. Such had been his state when his fatal illness began. The following are the notes taken at the time.

December 13th. This morning he complained of slight pain in the chest, with difficulty of breathing. He thought he had again caught cold. He was transferred to the sick-ward for further observation.

December 14th. There was well-marked pneumonia of the lower half of the right lung. There was also some dulness at the base of the left lung posteriorly. It was impossible to examine the heart satisfactorily, on account of his waywardness. So far as could be made out, there was no decided hypertrophy; but the action was feeble and markedly irregular. Pulse 104, very irregular. He was ordered sago, milk, beef-tea, etc. Temperature at 7 P.M., 101.4.

December 15th, 11 A.M. Temperature 102; pulse 98, of same character; respirations 37. He complained a good deal of pain in the chest; but his cough was not particularly troublesome. Temperature at 7 P.M., 101.

December 16th, 11 A.M. Temperature 100.2; pulse 72; respirations 38.—7 P.M. Temperature 100.6.

December 17th, 11 A.M. Temperature 99.8; pulse 100, still irregular; respirations 40. He did not take much food except milk. The cough was not very troublesome; the expectoration was not very copious, but of a characteristic prune-juice colour. He was ordered four ounces of whiskey. His bowels were regular.

December 18th, 11 A.M. Temperature 98; respirations 40; pulse 104, very weak and irregular.—7 P.M. Temperature 100.4.

December 19th, 11 A.M. Temperature 100.4; respirations 40; pulse 103, of same character.—7 P.M. Temperature 100. The patient slept very little. His general condition was unchanged; but during the last day or two his face presented a peculiar pallor, difficult to describe, but very striking when seen.

December 20th, 11 A.M. Temperature 97.4; respirations 38; pulse 106, very weak and irregular.—7 P.M. Temperature 104; bowels still regular.

December 21st, 11 A.M. Temperature 96.4; respirations 40; pulse 72, of same character.—7 P.M. Temperature 97.4. He took fluid food very well. His mental state had undergone no change in the course of this attack.

December 22nd, 11 A.M. Temperature 96.4; respirations 34; pulse

64, very weak. During his present illness, he had seldom lain in bed, but had preferred to sit more or less upright, supported by pillows, as in that position he felt more comfortable and his breathing was easier. His appearance was not that of a man dying of pneumonia; it was rather that of a person in a state of collapse.

December 23rd, 11 A.M. Temperature 92.4; respirations 32; pulse about 60, but very difficult to count, it was so very small and feeble.—7 P.M. Temperature 92.2.

December 24th, 11 A.M. Temperature 91; respirations 42; pulse about 80, very feeble.—7 P.M. Temperature 97.2.

December 25th, 11 A.M. Temperature 93; respirations 38; pulse about 67, but hardly perceptible.—7 P.M. Temperature 94.2.

December 26th, 11 A.M. Temperature 93; respirations 40; pulse about 60, very weak.—7 P.M. Temperature 94.2.

December 27th. He died this morning at 12.10.

This case is a good illustration of the anomalous symptoms sometimes presented by the insane. Though the record is not complete, as no *post mortem* examination could be obtained, it appears interesting to me as being the only one of its kind that ever came under my notice. It is well known that, in the sane and insane, cases of acute phthisis, typhoid fever, etc., will run their course and the thermometer fail to indicate any considerable and persistent rise in temperature. When such occur in the insane, some vague remark is made about disease of the nervous system. In the case just recorded, all the symptoms point to failure of the heart's action, probably from fatty degeneration. Be that as it may, it has greatly puzzled me, and I report it for the benefit of those more familiar than I am with some departments of clinical medicine.

#### LOUGHBOROUGH INFIRMARY.

##### DEGENERATION OF A MOLE INTO AN EPITHELIOMA.

(Under the care of Dr. HUTCHISON.)

FOR the report of the following case we are indebted to Glynn Whittle, B.A., M.D., Resident Surgeon.

On February 19th, J. H., a labourer aged 68, was admitted into the Infirmary, under the care of Dr. Hutchison. The patient had all his life had a large mole, of the size of a florin, on the left buttock. It did not increase in size until eight months ago, when he was accidentally thrown down, a projecting object coming into sharp contact with the mole. It then began to grow rapidly larger, attended with constant pain. On the patient's admission, the tumour had the character of an obviously malignant growth. It was circular in form, with a diameter of about four inches. Towards the circumference, the surface of the tumour was callous, indurated, and raised the sixth of an inch above the level of the skin, but the central parts were mottled and ulcerated, giving rise to an offensive but not very plentiful discharge. There being no enlargement of the lymphatic glands, by a circular sweep of the knife Dr. Hutchison removed the tumour, with a margin of healthy skin. Fortunately, the cancerous roots did not penetrate deeper than the subcutaneous fat. There was no hæmorrhage.

Microscopically, the tumour was found to be composed of squamous epithelial cells of various sizes, nucleated and caudate, arranged in one or two places in globular masses of concentric lamellæ. In other parts, the epithelioma was undergoing fatty changes. No trace of alveolar stroma could be found, but the fibrous structure is generally, though I believe not invariably, absent in epithelial cancer.

LAMBETH.—Mr. Archer Farr begins his report by honestly stating that he has followed the plan adopted by his predecessors of deducting the deaths in public institutions, and of non-residents, without adding on the deaths of parishioners in the various hospitals, including those of the Asylum Board; so that the calculated death-rate is probably more than 1.5 per 1,000 inhabitants below the true number. The report is for the year ending March 30th, 1877, so that the difference cannot be accurately calculated. The population is estimated at 233,927; the birth-rate at 38.3, and the death-rate at 20.56 per 1,000, after deducting 519 deaths of non-residents, but including the deaths of 100 residents in the Small-pox Hospital. There were 32 deaths from diphtheria, some of which occurred in houses where the drains were stopped up, others where the water was contaminated with sewer-gas, and another where the rain-water pipe was defective, so that sewer-gas could escape into the bedroom of the patient. There were also 50 deaths from typhoid, as well as 7 from typhus. The small-pox epidemic commenced in March 1866, directly after the Stockwell Small-pox Hospital was reopened. A large amount of sanitary work was carried out, including the disinfection of 1,198 houses in which small-pox and fever had occurred.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 26TH, 1878.

CHARLES WEST, M.D., President, in the Chair.

ON THE CONDITION OF THE SKIN IN *TINEA TONSURANS*.  
BY GEORGE THIN, M.D.

THE paper gave an account of the appearances seen in sections through the entire thickness of the skin of a horse affected with ringworm. The author alluded to the evidence on which the identity of the disease in that animal and in man had been established, and to cases in which the trichophyton tonsurans had been transmitted from the former to the latter. The skin was examined in both the earlier and the advanced stages. The spores of the trichophyton tonsurans were found amongst the most superficial scales of the horny layer of the epidermis. They were found in the cutis only on the shaft of the hair and between the shaft and the internal root-sheath. The spores in no instance were found in the root-sheaths, the hair-root, or hair-papilla, nor in the connective tissue surrounding the hair-follicle; that is to say, the spores were never found in actual contact with living tissue, the space between the internal root-sheath and the hair-shaft being analogous to the most superficial stratum of the horny layer. The affected hair first bent, and then broke at a point usually midway between the rete mucosum and the hair-root. This the author attributed to the disintegrated hair yielding to the pressure produced by the normal growth of the hair-shaft upwards. The changes found in the tissues of the cutis and rete mucosum were sometimes extensive, and were similar to those found in inflammation from whatever cause it arose. The spaces between the bundles of connective tissue were more or less infiltrated with colourless blood-corpuscles (pus-cells); the walls and immediate neighbourhood of the blood-vessels being thickly studded with them. Retrogressive changes were found in the nuclei of the cells of the rete mucosum, and at some parts the epidermis had completely broken down, leaving the cutis denuded. In the latter case, the surface was found covered with pus-cells. Small localised abscesses were found in the external root-sheath and in the rete mucosum. The cell-infiltration descended along the veins to the deepest parts of the cutis. The author, finding these well-marked inflammatory effects in tissues which contained no vegetable organism, suggested that they were due to the irritation which is produced by the absorption of soluble matter set free during the growth of the fungus. The parasite found its habitation amongst epidermic structures, and could only assimilate by decomposing them. This theory seemed to be the only reasonable one, because the effects produced were far in excess of those which might be expected to follow the pressure attending the distortion of the hair. The incapacity on the part of the fungus to exist in living animal tissues explained the *modus operandi* of the very numerous methods of curing ringworm. Many of the substances applied were simple irritants, whilst the parasitocides in common use were also irritant. Inflammation, when sufficiently acute, cured ringworm, as was shown by the fact adduced by the author, in which a simple wound through a ringworm-spot cured the whole patch. It was thus that the beneficial effect in chronic cases of a continued slight congestion was explained. The author further pointed out the probable injurious effect on the general health of the continued absorption of the irritating matters produced by the growing fungus.

Dr. F. TAYLOR said that a few months ago a child with cerebral tumour came under his care, who also had a ringworm on the left side of the neck. For two months before the child's death, no treatment was applied to the ringworm. After death, he removed a portion of the skin, and subjected it to examination; which, however, was not yet completed. So far as he had gone, he agreed with Dr. Thin as to the position of the spores. The shaft was crowded with them, but the inner and outer root-sheaths were free. As regarded secondary changes, he had seen little of them; but possibly the case would be different in a healthy child and in one the subject of diseases.—Mr. GASKOIN said that Dr. Thin's remarks tended to encourage one to attempt epilation as far as possible. All the remedies which had acquired a reputation for the cure of ringworm acted by producing irritation; he could recognise no specific action in any of them. He showed drawings of a case of foreign ringworm, in which there was a white ridge with a red border on each side.—Dr. COUPLAND asked how the spores produced an irritant fluid in growing. Was there any analogous process in the growth of other fungi?—Dr. THIN said that the yeast-plant, bacteria, etc., decomposed matter in growing, and left a residue. In regard to the preparation of the specimens, if a piece of skin were hardened in alcohol and cut, and then put in potash solution, and examined with the

microscope for a time, there would be found to be a stage at which the spores stood out well-marked, and could be distinguished from the granules in the sebaceous glands, which they much resembled.

THE RESULTS OF ONE HUNDRED CASES OF PARACENTESIS OF THE TYMPANIC MEMBRANE. BY W. LAIDLAW PURVES, M.D.

Of the different methods employed, the knife, the trephine, acids, oils, and ointments, pancreateine, and the galvano-cautery, the galvano-cautery, combined with pressure and ointments, was preferred for maintaining, or attempting to maintain, a permanent opening, but the maintenance of such was exceptional. The frequent repetition of the paracentesis caused a permanent thinning at the spot perforated, which acted to a certain extent in the same way as a perforation. Of eighty-three individuals operated on, forty-six were benefited, temporarily or permanently. In cases of tinnitus, one-fourth benefited. In acoustic affection, no improvement occurred. Of thirty-nine cases of catarrhus drums, twenty-three were improved; five out of seven relaxed drums improved. Of twenty-one paracenteses for the removal of substances from the cavity, fifteen were benefited.

Mr. DALBY said that the operation of opening the tympanic membrane was first seriously proposed in 1868 by the late Mr. James Hinton, who performed it frequently, and published the results of his practice in the *Guy's Hospital Reports* in 1869. In 1870 and 1871, Mr. Dalby saw him perform the operation many times; sometimes he did it twice or three times in a day. In 1872, he (Mr. Dalby) read a paper on the subject before the Royal Medical and Chirurgical Society, pointing out to what cases the operation should be limited. He believed that certain diseased conditions of the lining membrane of the tympanic cavity, as where it was destroyed or thickened by calcareous deposit, explained some cases of deafness. If it were so, a different explanation must be assigned to the lining membrane from that generally accepted; it must be regarded as a protective membrane and a support to the ossicles of the ear. In his experience, the operation had not been very successful except where fluid was removed from the tympanum.—Mr. C. BROOKE said that Sir A. Cooper used to perforate the membrana tympani with the sharp end of a three-sided silver probe. This operation had been performed on him (Mr. Brooke) in 1817 or 1818, with complete relief. The opening had closed long ago; he could not say when.—Dr. BRANDEIS had for some time paid attention to the subject of paracentesis of the membrana tympani. He himself had been the subject of progressive deafness; and in 1871 he had paracentesis done by Dr. Weber-Liel of Berlin. The opening could not be preserved. He had also seen Voltolini's plan of operating; and thought that the galvanic cautery was the most successful method. Dr. Purves had made no distinction between perforation of the membrane (myringotomy) and excision of a portion (myringectomy). As regarded the means of keeping the cavity open, various biongies, small cannule, laminaria-tents, etc., had been used; but foreign bodies were not well tolerated. Two years ago, Voltolini proposed a method which was attended with satisfactory results. It consisted in perforating the membrana tympani at the posterior quadrant, and introducing a short cannula with a flange at one end.—Mr. CUMBERBATCH said that the possible injury to the remaining hearing power of the patient must be borne in mind in proposing the operation. The proceeding had not been successful in his hands.—Mr. LENNOX BROWNE said that, in cases of suppuration in the tympanum causing perforation of the membrane, it was very difficult to close the opening. He agreed with Mr. Dalby, that perforation should be limited to cases where it was desired to evacuate something from the tympanic cavity.

### HARVEIAN SOCIETY OF LONDON.

THURSDAY, MARCH 21ST, 1878.

GRAILY HEWITT, M.D., President, in the Chair.

*Tubercular Kidney.*—Dr. DE G. GRIFFITH exhibited the kidneys from a girl aged 19, who was supposed to have uterine disease, and who suffered from much irritability in the bladder and labia. She had pains in the suprapubic region. She died; and one kidney was found apparently normal, the other was the seat of tubercular pyelitis. A rupture was found at the junction of the kidney and the ureter. There was tubercle in other organs.—The PRESIDENT, Dr. FITZPATRICK, Dr. MORRIS, and Dr. C. J. HARE spoke.—Dr. MURRAY proposed that the specimen be referred to a Committee, who would report upon it to the Society.—Dr. Murray, Dr. Morris, and Dr. Griffith were then formed into a Committee.

*Intestinal Obstruction.*—Mr. CRIPPS LAWRENCE showed an India-rubber cup and tube for use in cases of intestinal obstruction; the cup forming a convenient receptacle for the tube, so that the instrument was

readily portable. The India-rubber was sufficiently transparent to show the fall of the water in it. If the cup were raised high enough above the patient, force sufficient to endanger the bowel might be raised.—The PRESIDENT said it was an ingenious and portable instrument.

*Relations of Diabetes to Gout.*—Dr. W. SQUIRE related several cases illustrating this relation. He said they not unfrequently alternated; and diabetes was common in persons of the gouty diathesis. It was not produced by change of diet. He then narrated some illustrative cases. He said the glycosuria disappeared during times of pyrexia.—Dr. WILTSHIRE spoke of a gouty diabetic patient.—Dr. FOTHERGILL referred to diabetes coming on at the finish of old-standing gout.—Dr. FITZPATRICK said that females were liable to glycosuria.—Dr. SQUIRE replied.

*Precipitate Labour followed by Syncope.*—Dr. ASHBURTON THOMPSON related such a case in a multipara. He said that every stage of the labour was hurried, and that the shock was not merely due to the sudden emptying of the uterus. The patient remained in syncope for three hours; it was followed by vomiting and feeling of icy coldness in the joints. At the end of twenty-five hours, she passed a clot of much firmness, forming a cast of the uterus, the vaginal end of it being almost white.—The PRESIDENT said the condition of the clot, which was exhibited, was due to the os squeezing it and driving out the red blood-corpuscles.—Drs. WILTSHIRE and GRIFFITH spoke; after which Dr. THOMPSON replied.

*The Diagnosis of Abdominal Tumours.*—Dr. ARTHUR EDIS read a paper on this subject, and related a series of cases illustrative of the difficulty of correct diagnosis. The first was one of spurious pregnancy. The catamenia ceased; there was morning sickness, and abdominal enlargement. Then, distinct movements were felt. At the spurious parturition, a medical man stayed with the patient from 10 P.M. to 7 A.M. Ultimately, the labour-pains disappeared. A turpentine enema brought away a quantity of flatus and feces, and the patient reconciled herself to a barren condition. The next case was one of uterine fibroid mistaken for pregnancy. In the third, extra-uterine pregnancy was diagnosed; but the case turned out to be one of omental cancer. In a fourth, malignant disease with ascites was taken for a multilocular ovarian tumour. In a fifth case, pregnancy was mistaken for an ovarian tumour; and in a sixth, the reverse of this. Dr. Edis said the diagnosis should rest mainly upon the objective data, and but little on the subjective data or the patient's statements.—Dr. C. J. HARE said mistakes more commonly arose from carelessness than from ignorance.—Dr. FITZPATRICK said that such mistakes were readily condoned by barren married women craving for children.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, FEBRUARY 23RD, 1878.

EDWARD HAMILTON, M.D., President, in the Chair.

*Ovarian Tumour.*—Dr. W. J. SMYLY showed a large ovarian tumour removed by Dr. Atthill, Master of the Rotunda Lying-in Hospital, on the previous day, from a patient aged 49, married thirty years, but childless. There was an abdominal swelling since Christmas 1876; but during the past few months the tumour grew apace, so that the girth three inches below the umbilicus increased from thirty-three inches last autumn to thirty-eight inches. The tumour was extremely adherent, and contained scarcely any fluid contents. The patient sank in a few hours after the operation.—The specimen was referred to a Committee to report as to its nature.

*Intracapsular Fracture of Femur.*—Dr. E. T. LITTLE presented three specimens illustrative of the modes of union in this injury. Case I was a woman aged 70. The accident happened long ago. The bone was light and atrophic. The cervix femoris was absorbed, so were the cartilages, and the true joint was obliterated. Slight osteophytic deposits had occurred. A new joint had formed. In Case II, that of a woman aged 54, who had met with the accident at least six years before, strong fibrous union had existed. A large gap anteriorly in the bone was filled with dense fibrous material. There were osteophytic growths also. Case III was especially interesting, for in it firm bony union had occurred. The fracture and the union were of great antiquity—the subject of the injury being a woman of advanced age. The bone was light, but cancellated tissue was thrown across the line of fracture. There were certain peculiarities in the case. Thus, the line of fracture was oblique, running down nearly to the trochanteric line, the lower fragment was laterally displaced backwards, and an osseous outgrowth passed up towards the head of the femur. There were traces of a fracture through the femoral condyles, to which second injury the abovementioned peculiarities may have been due.—The PRESIDENT suggested that the obliquity of the cervical fracture may have aided the

occurrence of bony union.—Dr. BENNETT attributed bony union to the impaction of the lower into the upper fragment.

*Carcinoma of Liver.*—Dr. J. W. MOORE showed a specimen of Farre's tubercle of the liver from the body of a woman aged from 45 to 50, a cook by occupation. She enjoyed good health until November 4th, 1877, when a shivering fit ushered in a protracted intermittent, or pseudo-intermittent, fever. In it the temperature at first ranged from 105 deg. to 97 deg. in a few hours. The patient had never been out of Ireland. There was no hepatic enlargement, nor was the spleen considerably or permanently enlarged. After an unsatisfactory convalescence, she noticed a fulness in the right hypochondrium, and physical examination revealed the presence of a large hepatic tumour, which was decided to be of a cancerous nature. There was never any jaundice, but towards the close of her life an extensive ascites formed. The right pleura also became so distended with fluid as to cause almost complete collapse of the right lung. This was the immediate cause of death. The liver was enormously enlarged, and studded with masses of encephaloid carcinoma, many of which presented the "cancer-navel". The peritoneum was chiefly healthy, so were the stomach, intestines, uterus, and ovaries. The mesentery and meso-colon abounded with infected glands, and the pancreas formed with the retroperitoneal glands a vast mass of disease which pushed the liver and stomach forward. The kidneys were healthy, though congested. The spleen was slightly enlarged. The gall-bladder was involved in a mass of the new growth.

*Tuberculosis in a Lioness.*—The Rev. Dr. HAUGHTON showed the lungs of an African lioness, which died after two months' illness in the Zoological Gardens, Phoenix Park, of what was apparently pulmonary tuberculosis. Dr. Haughton said that the animals usually died of a peculiar and limited lobular pneumonia, either primary or symptomatic of "Milzbrand", and accompanied by an extensive suppurative nephritis.

#### SURGICAL SOCIETY OF IRELAND.

FRIDAY, MARCH 1ST, 1878.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

*Rupture of the Tendon of the Gluteus Maximus.*—The PRESIDENT, having temporarily vacated the chair, which was occupied by Dr. COLLES, read a paper on the above subject. The case from which his notes were taken was, he said, almost unique; rupture of this tendon being amongst the rarest accidents in surgery. M. T., aged 63, farmer, six feet two inches in height, and powerfully built, when admitted into Steevens's Hospital December 26th, 1877, gave the following history. In October last, when trying to lift a heavily laden cart, while in a crouching position, he felt as if he had been struck a severe blow with a stone in the gluteal region; hearing, at the same time, a loud snap. He fell, and was carried home, suffering much pain in the part, which was considerably ecchymosed. When he was admitted into hospital in December, the gluteus maximus was soft and flabby, and there was considerable flattening of the whole gluteal region on the affected side; the other side being firm and full. A welt was also noticed running from the great trochanter towards the linea aspera. The limb was paralysed, especially the extensor muscles, and the toe drooped, the man having to walk with the help of two sticks. The rupture had taken place at the junction of the tendon with the muscle; this, the President said, was the most usual position in which rupture of tendons took place, though there was no absolute rule. He then recounted numerous cases of rupture of other tendons which had come under his notice, viz., rupture of the tendo Achillis, of the tendons of the thumb, of the plantaris, of the long head of the biceps, and of the tendon above the patella, which latter, he said, was much more common than that of the ligamentum patellæ. In one case of this kind, which came under his notice twelve weeks after the accident, the lower end of the tendon could be felt above the patella, behind which the finger could be pushed into the knee-joint. By the advice of a bone-setter, this man had been treated for twelve weeks by exercising the limb, passive motion being adopted when active became too painful. To explain the cause of the paralysis in the subject of the communication was not easy. The sciatic nerve did not seem to have been injured, for the tactile sensations and reflex movements remained perfect, and all the muscles were not equally paralysed. The most probable explanation seemed to be that it was an effort of nature to insure rest for the limb. A similar paralysis was often produced by a blow on a muscle.—Dr. CROLY thought the nerve might have been stretched or partially ruptured by the violent muscular action.—Dr. BARTON had met with a case which might throw some light on the subject. A man stepping out on a window-sill, while raising his body on the bent leg, fell. When taken

up, he felt great pain in the right gluteal region, which was flattened, and the muscle seemed to have lost its tone; there was a swelling of the size of his fist over the seat of injury. The patient could not get the gluteus maximus to act. He could flex and extend the limb, but could not rotate outwards without great pain. Dr. Barton thought that in this case some of the muscular fibres of the gluteus maximus, rather than its tendon, were ruptured; and suggested that the rotators outwards might probably also be injured. The man recovered so far as to be sent to the convalescent home.—Dr. MAPOTHER said that the President had rightly laid stress upon the unusual position in which the man was at the time; but for this the accident would not have occurred. He supposed that union of the tendon in these cases was not to be looked for.—Dr. BIGGER mentioned a case which occurred in the practice of Mr. Carmichael, where the gluteal muscles had been cut through in order to tie a wounded gluteal artery. In this case, the toe drooped for a long time, though no injury had been done to the sciatic nerve.—Dr. H. KENNEDY mentioned three cases of supposed rupture of the plantaris tendon.—Dr. BENSON related his personal experience of this accident. The sensation, he said, was as if he had been struck with a stone in the calf of the leg. From the rapidity with which he recovered—being confined to his house for only a few days—he was inclined to think that only some of the fibres of the muscle had been ruptured.—Mr. RICHARDSON confirmed the President's account of the patient's condition; after which the PRESIDENT replied.

*Saws for Amputation and Excision, and for the same purposes as the Trephine and Hey's Saws.*—Dr. BIGGER showed some saws for which he claimed originality.—Mr. RICHARDSON remarked that his amputation-saw was very similar to that pictured by Ambrose Paré in his book, except that Dr. Bigger's had a rotating handle, which could be fixed at any angle to the frame. His modification of Hey's saw certainly deserved credit for ingenuity, although the experiments performed by him to illustrate its action to the Society were hardly satisfactory, it being quite impossible, from its construction, to avoid wounding the subjacent tissues.

#### MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, MARCH 6TH, 1878.

FREDERICK A. HEATH, M.R.C.S., President, in the Chair.

*Progressive Muscular Atrophy.*—Mr. CULLINGWORTH exhibited a woman aged 41, the subject of progressive muscular atrophy. There was complete wasting of the lower half of the trapezius on each side. The rhomboids had disappeared, with the exception of a few fibres attached to the middle of the spinal border of the scapula, and the latissimus dorsi on each side was completely atrophied. The clavicular portion and upper half of the middle portion of the trapezius, the levator anguli scapulae, and the serratus magnus, were intact. The gluteus maximus was atrophied; the lower erector muscles of the spine and the flexors and extensors of the thigh upon the pelvis were weakened from partial degeneration. The hands and arms, including the deltoids, were unaffected, and the muscles of the calf were so prominent as to raise a suspicion of pseudo-hypertrophy. A portion of muscle withdrawn from the calf by the muscle-trocar had been microscopically examined, and found normal. The posterior borders of the patient's scapulae projected backwards from the posterior chest-wall, leaving a deep sulcus between the scapulae of the two sides, which was still further deepened when the arms were extended horizontally forwards. The internal borders of the scapulae preserved their parallelism with the median line. The partial atrophy of the glutei caused great difficulty in rising from the sitting posture and in ascending stairs; the weakness of the flexors of the thigh rendered it impossible for the patient to lift her heel from the bed when lying with the legs fully extended; while the weakness of the extensors of the spine and thigh caused lordosis.

*Fibroid Phthisis.*—Dr. DRESCHFELD showed a left lung, in which the upper lobe was in a state of fibroid phthisis, the lower lobe in a state of chronic lobular pneumonia; and in which the main bronchus was almost totally obliterated by a papillomatous growth springing from the bronchial mucous membrane. During life, the left half of the thorax showed marked retraction; there were dulness on percussion, loss of fremitus and loss of breath-sounds, and marked ægophony in the left infraclavicular and intrascapular regions. Further complications of the case were pericarditis and thrombosis of left femoral and subclavian veins.

*Intrathoracic Tumour.*—Dr. DRESCHFELD showed a sarcomatous tumour, situated in the posterior mediastinum, surrounding the descending thoracic aorta and pushing the left lung upwards. During life, the symptoms were dulness on percussion, loss of breath-sounds, and loss of fremitus, together with marked ægophony in the left infraclavicular

region. The lung itself was healthy. The tumour seemed to have sprung from the adventitia of the descending aorta; a second tumour, quite separate and distinct from the first, was found to surround a branch of the left pulmonary artery.

*Impetigo Figurata.*—Dr. YEATS showed a case of impetigo figurata on the cheek, of long-standing. The interest of the case lay in its simulating lupus, for which it might very readily be mistaken. The principal clinical features of the case which resembled lupus were the white cicatricial looking patches here and there apparent on the diseased surface, the thickened and elevated edges, and absence of pustules. The history of the case, however, including pustulation and incrustation, was conclusive in regard to its impetiginous nature, and throughout there were no lupus tubercles. The case was healing quickly under treatment adapted for chronic impetigo.

*Urethral Brush.*—Mr. WHITEHEAD exhibited an urethral brush, and detailed the method of using it in the treatment of chronic discharges.

*Malignant Disease (?) of Liver in a Boy.*—Dr. HUMPHREYS showed a boy aged 14, suffering apparently from malignant disease of liver. Inspection showed a marked bulging of the epigastric and right hypochondrium, and to a less degree of the left hypochondrium, with enlargement of superficial veins. On palpation, a somewhat elastic mass could be felt with a slightly uneven surface. Leftwards, the mass reached nearly to the splenic region, but the mass could not be felt. On percussion, the dulness of the mass was continuous with that of the liver. The boy had been obliged to give up work about two months previously on account of increasing weakness and pain of a colicky nature. A little before Christmas, it was noticed that the upper part of his abdomen was bulged. He had been losing flesh very rapidly. He had no jaundice or vomiting. His bowels were somewhat confined. His father had died of phthisis; and his mother was said to be dying also of that disease. After enemata had been given, two exploratory punctures had been made by the aspirator-trochar, but nothing had been drawn out except blood. Antisyphilitic treatment was tried without effect. The diagnosis of malignant tumour was then arrived at by exclusion.

#### NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THURSDAY, JANUARY 10TH, 1878.

G. B. MORGAN, L.R.C.S.I., President, in the Chair.

*Prevalent Diseases of the District.*—Mr. H. E. ARMSTRONG presented a report of the cases admitted to the Newcastle-on-Tyne Fever Hospital during the month of December, showing the occurrence of three cases of typhus.

*Traumatic Cerebral Hemorrhage.*—Dr. J. W. BRAMWELL showed the brain of a man aged 40, who had been admitted to the Tynemouth Union Hospital in a semicomatose condition. The right pupil was large; the left small. He could not articulate plainly, and could not understand what was said to him. There was no limb paralysis. Urine and feces were passed involuntarily. Ten days after admission, he was seized with severe convulsions, in which the right side was chiefly affected. The eyes were turned towards the right. He died the following day. A *post mortem* examination showed a fracture of the skull extending from the left zygoma upwards and backwards to the junction of the parietal bones. A large partly organised clot covered the anterior two-thirds of the left hemisphere. After death, it was ascertained that the patient had fallen downstairs seven weeks before admission.

*Adenoid Tumour removed from the Groin.*—Dr. HEATH showed this specimen, which weighed three pounds. A large short artery arising directly from the femoral artery entered the deeper surface of the tumour. This having been ligatured, the tumour was easily removed.

*Extreme Example of a Conical Stump.*—Dr. HEATH showed this specimen; also the patient, a boy, from whom it had been removed.

*A Mass of Calculous Fragments.*—Dr. HEATH showed this specimen. He had removed it by lithotomy from a patient aged 80. Lithotomy was preferred to crushing, because of the extremely irritable and inflamed condition of the bladder. The patient had previously undergone several "crushings" in London.

*Fractured Spine, of Thirteen Years' Duration.*—Mr. S. W. BROADBENT showed this specimen. The spinal canal was completely obliterated at the seat of fracture. The injury, which was caused by a fall of coal on the back, was followed by complete paraplegia and paralysis of the bladder and rectum; marked priapism continued for a month. After the acute symptoms passed off, the patient enjoyed fair health until a year before his death; he then suffered from intense pain in the

abdomen. For several months before death, he took a scruple of morphia daily. The cause of the pain was not ascertained, as a partial examination only was permitted.

*Empyema in a Child.*—Dr. WICKS showed a case of empyema in a child treated by free incision and drainage.

*Papery.*—1. Dr. E. C. ANDERSON read the notes of a case of Leucocythæmia accompanied by marked Oligopyrenæmia.

2. Dr. BYROM BRAMWELL continued his paper on Intracranial Tumours, reporting two additional cases.

## REVIEWS AND NOTICES.

**CLINICAL RECORDS OF INJURIES AND DISEASES OF THE GENITO-URINARY ORGANS.** By CHRISTOPHER FLEMING, A.M., M.D., M.R.I.A., late President and Fellow of the Royal College of Surgeons, Ireland; late Surgeon to the Richmond Hospital; Visiting Surgeon to Steevens's Hospital, Dublin; etc. Edited by WILLIAM THOMSON, A.B., M.D., Fellow and Examiner, Royal College of Surgeons, Ireland; Surgeon to the Richmond Hospital. Pp. 380. Dublin: Fannin and Co.

THIS book, which does not claim to be considered a systematic treatise, is made up chiefly of an account of, and remarks on, ninety-five cases of injury and disease of the genito-urinary organs in both sexes which have come under the author's care in hospital and private practice.

The first chapter is devoted to the pathology of the urine in its relations to surgery. The author then goes on to discuss obstructions of the urethra from injury, calculi, and other foreign bodies, and prostatic affections, each subject being illustrated by cases. Hæmaturia is next noticed. In the remaining chapters, stricture of the urethra, some diseases of the testis, scrotum, and round ligament, stone in the bladder and kidney, and the treatment of phimosis, successively receive attention; the whole concluding with remarks on morbid conditions of the urine in children.

Among the cases of obstruction of the urethra from various causes, is related one in which partial retention of urine resulted from pressure on the urethra by a three-ounce glass bottle, which had been introduced by the patient into his rectum for the purpose of relieving himself from piles, which, he imagined, had narrowed the gut and so caused constipation. This bottle was removed with great difficulty, on account of its extreme fragility. The operation was attended by much bleeding, but the patient made a good recovery.

In the chapter on stricture, Dr. FLEMING remarks that he has seldom seen an instance of contracted orifice, either acquired or congenital, in which there was not also a stricture in the region of the bulb. In such cases, it has sometimes happened to us to have searched in vain for the supposed deeper stricture after free division of the meatus.

In Chapter VIII, the author refers to an affection of the scrotum and penis which he has noticed in wine-bottlers, caused by placing the bottle between the thighs in order to drive home the cork. Irritation is thus set up, followed by an abscess, which bursts, leaving an unhealthy lupoid-looking ulcer, which is sometimes very obstinate. Passing on to the subject of stone, the author alludes to the unfrequency of lithotomy and lithotripsy in Ireland, and is of opinion that the average number of operations for stone in the whole of the Irish hospitals has not exceeded twelve *per annum* during the last hundred years. Four cases of lithotripsy—one of the patients being a boy three years of age—and eleven cases of lithotomy are reported, as well as a case of a woman from whom a calculus was removed by dilatation and partial section of the urethra. In the same chapter is related a case of fibro-calcareous tumour of the uterus, which ultimately involved the bladder, thus leading to a diagnosis of stone and consequent attempt at removal. In speaking of the treatment of phimosis by circumcision, Dr. Fleming describes an instrument which he uses for fixing the mucous membrane, so as to ensure cutting it and the skin on the same level. The drawing given of this instrument reminds us of nothing so much as of one of the Royal Humane Society's grapple.

The chromo-lithographs and other illustrations with which the book abounds are for the most part very good, though we fear the figures in Plate I will scarcely fulfil the author's intention of conveying a good idea of the appearance of the different urinary deposits as seen in the test-glass.

To conclude: though we are by no means sure that such a book as this was greatly needed, though some of the modes of treatment pursued may not be quite in accord with those most generally followed at

the present day, and though there is not much in the work that will help towards advancing our knowledge of the subjects included in it; still it is undoubtedly valuable as a record of the matured opinions and clinical practice of an eminent surgeon of very great experience, and may be read with advantage by those who take an interest in the study of disorders of the genito-urinary system.

### REPORT ON THE PREVALENCE OF PHTHISIS IN VICTORIA. 1877.

THIS is a report of a Committee appointed by the Medical Society of Victoria to inquire into the vexed question of the prevalence of consumption in that Colony and its alleged increase, and it is framed with the view of testing some of the conclusions deduced by Mr. William Thomson in his various analyses of the Statistics of Phthisis in Victoria, one of which was reviewed in this JOURNAL last year (*vide* BRITISH MEDICAL JOURNAL, June 23rd, 1877).

After all that has been said of late years for and against the climates of Victoria and Melbourne by private individuals, we look with interest on any systematic inquiry into the subject, especially if carried out, as this appears to be, by a body of medical men capable of thoroughly sifting the facts; and while we submit their conclusions and Mr. Thomson's reply, with which he has kindly favoured us, to wholesome criticism, we shall hail with delight any sound deductions on a subject affecting the welfare of not only the Victorians, but of the numerous British emigrants of various classes who visit Australia in search of health or profit. The following are the conclusions of the Committee:

1. The mortality from phthisis in Victoria is little more than half of that in England.
2. The rate of mortality from phthisis in Victoria has been perceptibly less of late years.
3. That rate is especially low among persons under 15 and 20 years of age, and has been very greatly reduced between 1861 and 1871.
4. The reduction of the mortality of young persons is to be explained by a comparative immunity among those born in the colony.
5. The apparent increase of mortality among young adults is due to the influx of phthisical persons from abroad.
6. The uniformity in the rate of mortality over the whole colony for a good many years is owing to certain insanitary conditions, operating especially in Melbourne, since for the rest of the colony the rate was reduced by about one-third between 1861 and 1871.

With regard to the first conclusion, we are inclined to agree with the explanation of the report: That the low rate of mortality from phthisis in Victoria is due to, not one but many causes, *e.g.* (1) the good and abundant food enjoyed by all classes, even by the lowest; (2) to the absence of injurious trades and to the less crowded state of the population; (3) to the smaller amount of inflammatory diseases of the lung, which lead to the development of consumption.

The second, third, fourth, and fifth conclusions relate to the question of the increase or decrease of phthisis in the colony; and, while we admit that the evidence adduced by the Committee fully warrants their arriving at nearly all these conclusions, we cannot help expressing a wish that they had treated with greater caution and less appearance of partisanship the remarkable exception of the increase of phthisis mortality between the ages of 20 and 25 for the year 1871 compared with that of 1861.

Here the report only gives us hypothesis, and no facts to support its fifth conclusion; and it would have been far better if the Committee had ascertained the number of cases of phthisis arriving in the colony during that period, instead of confining themselves to the probability of the increase being "due to the influx of phthisical persons from abroad". It is true they quote from the Victorian Year-book of 1876, that of 49 patients dying of phthisis in two years after their arrival in Australia, 42 were between 15 and 35, but what we want is a distinct statistical explanation for the numbers of 1871 and not for those of 1876; and we do not wonder at Mr. Thomson, in his reply, meeting the fifth conclusion by a statement that out of 407 deaths from phthisis only 94 occurred among those who had resided in the colony under ten years.

The contrast between the mortality from phthisis at Melbourne and in the rest of the Victorian colony is very great: being, in 1871, 22.29 per 10,000 inhabitants in the former, and 7.24 per 10,000 in the latter; that is to say, the Victorian rate is about one-third of the Melbourne one, which is nevertheless below the London one (26.6).

We think this report, with its valuable tables, is very acceptable, as clearly vindicating the sanitary character of the Victorian colony, in showing that its mortality, at all times low, has been gradually diminishing of late years. It at the same time admits that the Melbourne rate has not diminished at the same rate, and that this is due to certain unsatisfactory conditions, which ought to be ascertained.

## REPORTS AND ANALYSES

AND

## DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE  
ALLIED SCIENCES.

## TINCTURE OF CASCA.

CASCA (the bark of *Erythrophloeum Guinense*. Synonyms: "Cassa", "Gidu", "Saucy", "Sassy", "Doom", and "Ordeal Bark") has hitherto been of interest chiefly on account of its use as an ordeal poison on the Western Coast of Africa, where it is used as a test of the innocence or guilt of persons suspected of witchcraft, secret murder, and other crimes; but, recently, special pharmaceutical interest has been imparted to it by Dr. Lauder Brunton, who, in a lecture delivered at the Royal College of Physicians, London, published in the BRITISH MEDICAL JOURNAL of March 29th and 31st, 1877, gave the result of his investigations of it, and, in speaking of its physiological action, described it as "a drug which strengthens and slows the heart, contracts the arterioles, and increases the urine". The interest excited by this lecture was such, that many of the profession were desirous of availing themselves of such a valuable remedy; but, for some time, it was impossible to obtain a supply of the drug, owing, it is stated, to the precautions taken by the natives to prevent its falling into the hands of Europeans. Mr. J. S. Walton, F.C.S., to whom we are indebted for the information concerning this drug, succeeded recently, however, in obtaining, on behalf of Messrs. Gale and Co., of Bouverie Street, a consignment of casca bark; and, with a view to presenting it in the best form for administration, as well as to ascertain the dose and to separate the active principle, performed some experiments for Dr. Brunton, at whose request they are published, together with the following description of the drug, which had been derived chiefly from the writings of Proctor and others in the *American Journal of Pharmacy*. "Casca bark is obtained from *Erythrophloeum Guinense*, natural order Leguminosae, a tall tropical African tree with numerous spreading branches, which are covered with a smooth greyish bark, that of the trunk and larger branches being rough, corrugated and fissured, and of a reddish-brown colour, with light-coloured dots; the interior is generally of a deep brown colour. A smooth section of the bark exhibits numerous fawn-coloured cylindrical bodies, from half to two lines long, of a dense brittle texture, increasing in number in the older bark, and towards the inner surface. The bark has a faint odour and an astringent taste, without bitterness, leaving a slight tingling sensation. The astringency is due to tannic acid, which is present in the reddish portion, but not in the fawn-coloured spots; so rich is the bark in tannic acid, that it has been suggested that it might be advantageously used for the purpose of tanning in those parts where the tree grows naturally. The bark breaks with an abrupt fracture, and is readily powdered; but it requires great care, as the dust, when inhaled by the nose, causes violent sneezing." Proctor gives the following quotation from Bowditch's *Ashantee*

"Taking 'doom' is the infallible test when they consider the case too doubtful for human decision. The bark of that tree (viz., the 'doom plant') is put into a large calabash with water, so as to make a strong infusion; it is stirred up, when the suspected parties sip in turn. It operates immediately and convulsively as a most violent emetic and purge. Those who sip first may recover, and the dregs are frequently left designedly for the obnoxious."

A fuller and more interesting account of Casca bark, as an ordeal poison, is given by Winterbottom, in his *Sierra Leone* (vol. i, p. 129), and quoted by Proctor (*American Journal of Pharmacy*).

*Chemical and Pharmaceutical Examination.*—The following experiments were conducted in accordance with the suggestion of Dr. Brunton, for the purpose of ascertaining the amount of alcoholic extract, and of extractive matter, insoluble in alcohol, but soluble in water, present in the bark, and to separate the active principle.

*Alcoholic Extract.*—Knowing the difficulty of exhausting the bark, Mr. Walton deemed it advisable to reduce it to a very fine powder, which was attended with considerable personal inconvenience, and gave an opportunity of verifying the statement as to its action on the nose; for although he took the precaution to muffle the mortar, and to cover his nose and mouth with a cloth, yet he inhaled a sufficient quantity to produce violent paroxysms of sneezing, accompanied with a giddy feeling and oppression in the chest, as if it were contracted by means of a bandage, so as to render it difficult to draw a full breath: the eyes also assumed a glassy appearance, with a tightness in the forehead and a confused feeling in the head. Those symptoms continued for several

hours, and were also experienced, to a certain extent, by his laboratory assistant, who took part in powdering the bark.

Having obtained sixteen troy ounces of finely powdered bark, Mr. Walton packed it tightly in a strong cucumber-glass, with a perforated cork at the bottom, covered with a layer of coarsely powdered glass; the top of this percolator was fitted with a sound cork, through which was passed the end of a stout piece of glass tubing, about six feet long and one inch in diameter. With this apparatus, he proceeded to exhaust the bark, by means of column pressure, with alcohol of 56 deg., and continued to percolate until the spirit passed through colourless. The resulting tincture, on being distilled, yielded a reddish-brown extract, in the proportion of twenty-five per cent. of the bark used.

*Aqueous Extract*, or extractive inseparable by alcohol, was obtained by passing distilled water through the powder left in the percolator, after exhausting with alcohol; the aqueous solution, on being evaporated, left a hard extract of a deep brown colour, weighing two hundred and twenty grains.

*Active Principle.*—This was obtained, in small quantity, by exhausting the bark with water acidulated with sulphuric acid, neutralising with ammonia, which gave a reddish-brown precipitate, which was separated by filtration, washed with distilled water, and mixed with purified animal charcoal, and dried over a water-bath. It was then boiled with absolute alcohol, filtered, and the filter washed with more alcohol. This solution, on being concentrated, possessed a greenish fluorescence; after standing a few days, it was found to have yielded minute acicular crystals.

Having thus far completed the experiments indicated by Dr. Brunton, Mr. Walton proceeded to prepare for him solutions containing definite amounts of alcoholic extract and of aqueous extract.

In order to prevent any confusion or mistake in the nomenclature of this drug, owing to its similarity in name to cascarrilla, sometimes abbreviated "cascar," it has been suggested that the tincture, which is the preparation recommended to be used, should be called "tinctura erythrophloeæ", and the alkaloid "erythrophleine".

## SELECTIONS FROM JOURNALS.

## PHYSIOLOGY.

THE THEORY OF SLEEP.—A. Strumpell (*Pflüger's Archiv*) reports the case of a patient aged 16, the whole of whose cutaneous surface was completely insensible, so that the strongest stimuli applied to the skin did not excite any expression of pain. A similar anaesthesia was shown in nearly all the accessible mucous membranes of the body, and muscular sensibility was completely wanting. In addition to this, there was a complete loss of smell and taste. Finally, the right eye was amaurotic, and the left ear deaf; so that, when the left eye was bound up and the right ear stopped, there was no further avenue of stimulus to the patient's brain. When the latter experiment was actually carried out, the patient in about five minutes sank into a deep sleep, from which he could only be roused by the stimulus to the ear or by the stimulus of light; he could not be shaken only. When he was left to himself, he awoke in the course of the day, after many hours' sleep, either through internal stimuli or from the excitation of the brain through slight and unavoidable stimuli from without.

## DISEASES OF CHILDREN.

PNEUMOTHORAX IN A NEW-BORN CHILD.—Dr. Carl Ruge (*Zeitschrift für Geburtshilfe und Gynäkologie*, Band ii, 1 Heft) describes the appearances found in a child which was easily delivered by the feet. At first, it was somewhat in a state of asphyxia; it afterwards cried a good deal, but died suddenly twelve hours after birth in a state of cyanosis. About twenty-four hours after death, there was found to be a swelling of the sternal portion of the left sterno-mastoid muscle, great enlargement of the suprarenal bodies by effusion of blood into their parenchyma, and pneumothorax with hæmatothorax in consequence of rupture of the pleura. Air escaped on opening the thorax; the heart was displaced to the right, quite beyond the middle line. The right auricle was distended with a large fresh blood-clot. The left lung contained air in parts only; the pleura showed ecchymoses; at the base was an emphysematous bulla as large as a pea; and on the lower and posterior lobes, passing from above downwards, was an irregularly notched rent 3 centimètres (1.2 inches) long. The author supposes that the pneumothorax was the result of violent inspiration in consequence of the obstruction of the left lung by mucus, meconium, etc.; and that the emphysema, at first alveolar and afterwards subpleural, caused rupture of the pleura, probably before birth.

## BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

## BRITISH MEDICAL JOURNAL.

SATURDAY, APRIL 6TH, 1878.

### THE SPECIAL GENERAL MEETING.

THE Special General Meeting at Birmingham of the Association on Tuesday was less largely attended than possibly many may have expected. The more generally interesting and important of the two subjects to be discussed, however, had already lost most of its temporary importance by the judicious manner in which the Committee of Council had dealt with it at their last meeting. They had already resolved to frame a by-law which should set at rest any doubts as to the valid effect of the Edinburgh vote on the admission of women; and the question was thus absolutely narrowed to the question of proceeding in respect to the two ladies who had been elected prior to that date. There is no doubt as to the powers possessed by the Association to take steps for causing a member to "cease to belong to the Association"; and it seems equally obvious that, when that step is taken avowedly for the mere reason of sex and to meet the objections raised by a large number of associates on that ground, there is no question of personal imputation involved. On the other hand, such a proceeding is, it is understood, likely to be objected to by many as savouring of illiberality, and of what must be called, for want of a better name, impoliteness. Moreover, there are preliminary points to be settled which have been raised as to the actual legal status. The final settlement of the question necessarily belongs, according to the by-laws of the Association, to the annual general meeting; and by that time some general agreement may be arrived at as to what is to be done with the two ladies. Meantime, that is a question which does not seem greatly to agitate the Association.

Hence the main honours of the meeting were reserved for the two motions of Dr. Grigg relative to Reports of Proceedings and the new business arrangements entered on by the Committee of Council. These resolutions appeared to have commended themselves in theory to a large number of members; and it was stated that they had received the support—on paper—of about 2,000 members, including many well known names in various parts of the country; while only a few score had declared dissent. But in such a case that decision only could be ultimately valid which was arrived at after the hearing of *vis à voce* statement, and which was expressed by attendance at the meeting formally called by requisition. The three hundred London members who signed the requisition for the meeting were represented in Birmingham by only three; and whatever may be the influence of absence in increasing the affections, it has not the same power of convincing the reason. Had the questions raised by Dr. Grigg as to the correctness of the estimates and wisdom of the choice of site for the new offices been raised earlier, they might have received a solution uncomplicated by the important considerations which could not fail to influence their discussion at the stage at which they came under notice; but, so raised, they came to be treated as involving a vote of confidence in the Executive Committee of the Association. That is a perfectly constitutional way of meeting such an issue at a large public meeting. It could have but one result when the question came to be fairly put and

considered. The executive can point with satisfaction to the results of the last decennium, and especially to the financial results achieved by the scheme of reorganisation of business carried out by the Committee of Council in 1871, on the recommendation of a subcommittee consisting of seven members, of whose number it is sad to remember that Sibson, Clayton, and Southam are already gone; but of the remaining members of it, Falconer, Husband, and Chadwick, are among those who most warmly endorse the present further change, which is, indeed, only the full development of what was then proposed. So far as the propositions before that Committee were adopted by them at the time, and recommended to the Committee of Council and carried, they resulted in the appointment of a permanent business officer at the London office, with a concentration of the business departments under one head, for which purpose a business manager and general secretary was appointed. The financial results of improved management at once showed themselves. A prompt collection of revenue and careful checking of business details produced an immediate surplus of revenue over expenditure, which was at first devoted to wiping off bad debts and irrecoverable arrears, which figured for large amounts in the accounts. The increase continued to grow, and incumbrances were successively cleared off. Ready-money payments admitted of further considerable economies; and not only were the payments of the year met by actual receipts, leaving a considerable balance of good assets, but, later on, realised savings began at the rate of about a thousand a year.

Meantime, much had been done to make all departments of the Association share in the advantages of this increasing prosperity. The JOURNAL was from time to time enlarged, and no reasonable means were spared to make it more suited to the exigencies of the constantly increasing number of readers, who were themselves largely contributors to the prosperity of which they enjoyed the benefit. A system of Annual Scientific Grants was commenced for the support of researches in aid of medicine, of which the amount was proportioned to the claims sent in rather than limited to any hard and fast sum; while liberal grants were made to other Committees (as, for example, £100 last year to the Joint State Medicine Committee), and so on. Nevertheless, a fund of between £2,000 and £3,000 of remaining surplus was accumulated.

It was natural at this stage to consider whether the permanent office and head-quarters of the Association might not with advantage be improved. It is well-known that these, although they have gradually expanded from a little compartment in a printer's shop and have spread into the next house, are neither convenient nor dignified; but rather the reverse.

In considering the question, the Committee reverted to a suggestion made, in the original report for the reorganisation of the business-management, to the abovenamed Subcommittee by the Editor in 1871. That report includes an estimate of the expenditure for composition by a staff of printers specially salaried by the Association, as compared with the actually then existing contract price in bulk, and it showed an apparent saving. At and up to that time, it should be explained, the Editor had for some years acted as *amicus curiæ*, and, beyond literary duties, had voluntarily given a great deal of time and attention to the development of the business resources of the JOURNAL. Subsequently to that period, and concurrently with the appointment of a permanent business officer at head-quarters, such matters passed advisedly, and according to the scheme adopted, into the hands of that officer, under the supervision of the Committee. Now that the question of improving the offices and finding more respectable rooms for the Committee meetings and for administrative purposes arose, it was natural that the question of composition, or setting up the type of the JOURNAL, by a special staff should be resumed. It was so resumed and discussed by the Committee and manager; and upon an independent report (of the

details of which we have no cognisance), it was decided that it would be economical and advantageous to take certain premises in the Strand for the purposes, and to undertake composition. The site of these premises and the details of expenditure have been now very fully discussed and unfavourably criticised by Dr. Grigg, who has recently joined the Committee of Council as a representative of the Metropolitan Counties Branch.

It would be quite beside our purpose to enter into any analysis of the criticism of Dr. Grigg; he has already expressed his views in a very ample, independent, and, we must add, a very able, manner. He maintains that the proposed change will be neither economical, on the data stated, nor efficient. He has incidentally the advantage of some special knowledge of the subject, and evidently also of a careful study *ad hoc*. It is clear, however, that here also the Committee have satisfied their own mind by an independent investigation that the course proposed is, notwithstanding the economical objections urged by Dr. Grigg, one which is worthy of adoption in the balance of considerations; and they treated this also as a question of confidence. Mr. Husband was able to show very effectively that considerable economies have been effected thus far by abolishing "middlemen" in dealing; and he is satisfied that this will be so here also, although avowedly this is a matter of greater complexity.

We shall only remark here that the business question at issue is hardly of so much final importance as might possibly be supposed from a bare perusal of the arguments. Dr. Grigg may be right in his effective statement of the actual cost when all is brought into account, of the difficulty of realising a profit in employing a special salaried staff of printers. On the other hand, many of the expenses may be set off against the comfort, convenience, and respectability of suitable business accommodation and the combination of the administrative and executive work under one roof. Even if it be granted that, in consequence of the imperfections which he alleges in any existing estimates, due allowance is not made for capital spent at the outset, yet something may be allowed for the undoubted commercial advantages of a suitable office for a journal in a locality consecrated to journalism; the capital expenditure intended will barely exceed the probable surplus of the year, and there is every reason to believe that the ultimate result will continue to show an excess of annual receipt over expenditure. A Committee which has succeeded so well in the past years in realising an annual surplus could even afford to be convicted of underestimating some of the items which Dr. Grigg skilfully impeaches.

There remains the question of providing "suitable professional apartments"; by which is apparently meant something in the nature of a permanent reading and reception room, with strangers' register and other conveniences of the kind, such as are temporarily provided at the annual meetings. This also, we think, may be looked for, possibly at no distant time, as being quite within the probabilities of the resources of the Association after the present change of business headquarters has been carried out. The Obstetrical Society of London has provided such professional headquarters for its members at no great cost; and the Association will probably, without much strain upon its increasing resources, be able to do something of the same kind, on a suitable scale, at no distant time, if Mr. Jonathan Hutchinson's plan be duly matured and find general favour amongst the members when brought forward.

#### MEDICAL REFORM.

TWENTY years have elapsed since the British Medical Association, then numbering about twelve hundred members, was instrumental in passing the Medical Act of 1858, which secured reciprocity in the matters of practice to the inferior corporations, but did not enjoin uniform fees or uniform examinations. An unworthy competition

downwards in the granting of licences has, therefore, continued, and, at the present day, a licentiate of any one of the medical authorities, it may be at a cost of half a guinea, it may be in one single branch of the profession, is entitled to be placed on the *Medical Register*, and is thereby constituted a regular medical practitioner, who may with impunity practise all branches of the profession when, to the detriment of the public, he may in reality be only qualified in one. The authorities in the army and navy have not relied on the efficiency of the tests to which registered medical practitioners may have been subjected, but insist on a further examination, at which examination many have been proved incompetent, before entrusting our soldiers and sailors to their care. The Poor-law authorities likewise are not content with the simple qualification which legal registration as a medical practitioner confers, but exact what is known as a double qualification before appointing a medical officer to take charge of the sick poor. The army and navy, and the so-called paupers, are, at least to some extent, protected by the responsibility attaching to the heads of each department; it is the general community alone which is not secured from falling into the hands of half-educated men when stricken by accident or illness.

In the debates on the passing of the Act of 1858, Mr. Walpole stated "that the rivalry between the colleges in conferring degrees led to nominal or worse than nominal examinations". That rivalry and that competition still exist; there is no rule, no enactment to prevent a candidate rejected by one examining board from presenting himself before another which may, on easier terms, as regards both examination and amount of fee, confer on him the right of being placed on the *Medical Register*. Such a condition of things has convinced every disinterested person conversant with the subject of the necessity of an amended Medical Act; and the Medical Reform Committee of the British Medical Association, in conjunction with the late Mr. Headlam, drafted a Bill in accordance with the principles for which the Association has unswervingly contended. The connection of the name of Mr. Headlam with medical reform; his thorough mastery of the subject in all its details; the important part he played in the passing of the Act of 1858, are confirmation strong that he would not attach the weight of his name and influence to any immature or badly conceived measure. The necessity for reform was not disputed. The Bill of the Association had Mr. Headlam's entire approval, and had certain objects.

1. The first object was admission to the General Medical Council of direct representatives of the profession in the proportion of one-fourth of the numbers of the Council. On this point, it may be simply stated that the profession of the United Kingdom, numbering upwards of twenty thousand, has no representative in the General Medical Council. The profession outside the universities and corporations is unable to influence it.

A deputation from the British Medical Association waited on the General Medical Council on June 30th, 1868, in consequence of an almost unanimous vote, at the annual meeting of the Association in Dublin in 1867, to submit "that eight members, to be elected by the registered members of the profession, should be added to the General Medical Council". That number was one-fourth of the members of the General Medical Council; but the deputation also stated that "the Association is of opinion that, if the Council should deem it advisable to recommend a diminution in the number of its present members, then a corresponding reduction may be made in the proposed number of the representatives of the profession".

The late Mr. Nunneley of Leeds, who had been for years on the Medical Reform Committee of the Association before the Medical Act of 1858 was passed, stated that "it was always intended that a portion of the Council should be elected by the profession, but difficulties had prevented this from being carried out"; the difficulty being the non-existence before the Act of any register of the profession. The late Mr. Southam, also on the Reform Committee, repeatedly stated that, in the conferences with the Committee preceding the Act, it was

understood that, when the *Register* was completed, the profession should have its representatives in the General Medical Council. The late Mr. Headlam has made similar statements. The General Medical Council to the present time have made no move in favour of this desire of the Association.

Now, if Mr. Cowper-Temple, in the debate of June 2nd, 1858, on the second reading of the Medical Act, was right in saying, "the medical practitioners throughout the country, numbering about 15,000, and who were represented by the British Medical Association, were favourable to this Bill", with far greater reason may the Association now be said to represent the profession, when it numbers upwards of seven thousand members, and when the desire for the modification of the Council has been reaffirmed at every succeeding annual meeting.

As the General Medical Council exists, we find in it, in overwhelming proportion, representatives of the very corporations whose action it is sought to reform; and thus, as before the Act of 1858, so now, the conflicting and opposing interests of the corporations constitute the chief barrier to that reform which the Association demands in the interests of the public. In the present General Medical Council, we have further the striking, the startling anomaly of a Council at variance with the body which called it into existence—a condition which is still further illustrated by the fact that a memorial for its modification, with upwards of 10,000 signatures, which emanated from Birmingham, under the auspices of the present President of the Birmingham and Midland Counties Branch, was also presented to the Council, and equally shelved and disregarded.

Is there no room for hope that the General Medical Council will yet take some steps to terminate the absurdity of a condition, in which it places itself in opposition to the voice of the members of the medical profession?

The Association, the profession, is committed by its unvarying action to the modification of the General Medical Council, and will therefore strenuously oppose any Bill which does not provide for it.

2. In moving the second reading of his Bill of 1858, Mr. Cowper-Temple said that he had in view "to raise to a uniform standard the education and qualifications of medical practitioners". To do this has been equally the object of the Association from the first dawn of its existence. An examination founded on equal requirements and equal fees, conducted by a conjoint examining board for each of the three divisions of the kingdom, was provided for by the drafted Bill of the Association. The Bill of the Government now before Parliament errs fatally in omitting this, while lauding the efforts of the English medical authorities to combine in one examining board. In Scotland, it simply permits the conjunction of two or more; but this permission is given in the Medical Act of 1858. The mischief is, that they will not avail themselves of it. So also with Ireland; voluntarily they have been unable to combine. First, the five medical authorities in Ireland tried; that was the quinary scheme, but it failed. Four then tried; the quaternary, only again to fail; and so on, a ternary, and last a binary scheme followed, with similar lamentable results; leaving the Irish authorities each acting for itself. The Association does not believe in voluntary conjunction, from which, as from the treaty of Paris, any of the parties may at any opportune moment secede; the Association believes only in compulsion, where selfish interests are to be sacrificed. Private individuals, like Quintus Curtius, may devote themselves for the public weal; corporations never.

Better no Bill than that this permissive Bill of the Government should pass, while in their strength they might worthily exact, backed as they would be by the profession, a Bill which, while settling once for all the portal to the profession, would be a boon to the public.

Medical reform has now reached a crisis; we shall return to it again and again. In the meantime, we direct attention to a report of the Medical Reform Committee which met at Birmingham on Tuesday last, and urge the members of the Association to support the Committee.

## THE CHANGES IN THE ARTERIOLES IN BRIGHT'S DISEASE.

THIS subject has not received much attention until lately from continental observers, probably because the granular form of renal disease is relatively rare in most parts of Germany. We recently drew attention to Professor Thoma's elaborate descriptions and measurements of the changes in the blood-vessels, and his paper is now followed by an article from the pen of Dr. C. A. Ewald, in the January number of the same periodical (*Virchow's Archiv*). After referring to the history of the cardio-arterial changes (in which, by the way, he speaks of Bright as "John" Bright, a rather amusing instance of Malapropism), he gives the result of his observations upon the vessels of the pia mater, and states that he has found decided thickening of the muscular wall, but no evidence of the arterio-capillary fibrosis, the lymph-sheath being, as a rule, little thickened. His observations extended over fifty-one cases in which the cardio-vascular changes were looked for; of these, the first twenty-one were cases of "nephritis interstitialis" and "nephritis interstitialis et parenchymatosa", in which fifteen showed hypertrophy of the heart and small vessels, five hypertrophy of the heart only, and one hypertrophy of the vessels only; the second series consisted of sixteen cases of "nephritis parenchymatosa" in which none had hypertrophy of both heart and vessels, five had hypertrophy of the heart, and sixteen were without abnormality of these organs; finally, of twenty-four cases of other diseases, four had hypertrophy of the vessels without affection of the heart, in twelve the heart alone was hypertrophied, and eight were complicated by nephritis parenchymatosa. Of all these cases, however, he says only three were very small contracted kidneys. From these data, he concludes that "nearly all cases of nephritis interstitialis chronica granularis have hypertrophy of the muscular substance of the heart and vessels". For the heart, this rule seems to be absolute; for the vessels, some qualification is necessary. Of the mixed forms, with kidneys weighing less than 300 grammes (10½ ounces), two-thirds had cardio-vascular hypertrophy, one-third only cardiac hypertrophy, and of those over three hundred grammes in weight, all had hypertrophied hearts, and none hypertrophied vessels. Also, in rather less than a third of the cases of parenchymatous nephritis, simple hypertrophy of the heart was present. From his observations, he concludes that "secondary nephritis and enlargement of the heart, due to other causes than primary renal disease, do not lead to hypertrophy of the vessels". He argues, therefore, that, as each of these may exist independently of the other, neither can be considered the cause of the other. In discussing the probable causation of these conditions, he remarks that Johnson's theory has a basis of probability in Ludwig and Mosso's experiments upon the local effect of poisoned blood on the vessels, but it leaves out of account the action of the depressor nerve, which is excited by increased intracardiac pressure, and produces relaxation of the arterial tonus, so that a new element would have to be introduced into the hypothesis, that of paralysis of the depressor nerve. He thinks, too, that the absence of cardiac hypertrophy in amyloid and atheromatous thickening of the arterioles, and the presence of cardiac and vascular hypertrophy or simple cardiac hypertrophy in other forms of renal disease, speak against the vascular changes as causes of the heart-affection. He inclines to the older view of the obstruction being in the capillaries; for, he says, Ustimowitsch and Gruntzner found that injection of urea into the blood caused increased blood-pressure and urinary secretion with dilatation of the renal vessels, which could not be explained on any hypothesis of arterial contraction, except by supposing that, while the renal arterioles were dilated, those of the rest of the body were contracted; but this difficult conclusion is avoided if we admit the greater friction produced in the capillaries by the urea-laden blood. The secretion of urine must depend upon the pressure in the glomeruli and the flow of blood to the same, and this

pressure is only possible when the obstruction is on the farther side of the glomeruli, and the free flow of blood to them is only possible by the arteries being dilated. This explains why, when the blood-pressure is artificially raised, *the kidney whose nerves have been cut alone secretes*. In Gruntzer's experiment, he injected saltpetre solutions, and found that, if the blood pressure were not artificially raised, and the renal nerves on one side were divided, there was copious urinary secretion from both kidneys and slight rise of blood-pressure, as the *capillary* resistance was the same in both; but when the blood-pressure was further raised by stopping respiration, the urinary secretion *sank on the side of the undivided nerves*, and rose on the other. This shows that the secretion depends not upon the general blood-pressure, but upon the pressure in the glomeruli, and gives great support to the view that the polyuria of granular kidney depends upon capillary resistance. How this resistance causes hypertrophy of the heart and vessels, is worth consideration; it is generally admitted that there is no peristaltic action in the small vessels. Ewald believes that it is quite independent of central nervous influence, and is a purely mechanical effect of the increased blood-pressure. The walls of the blood-vessels possess the power of reacting against pressure from within, and always endeavour to conserve their normal calibre; by such constant and prolonged efforts as are required by the increased pressure in this disease, their walls undergo thickening. The hypertrophy of the heart also finds its cause in the increased tension within the aorta, and he would place the series thus: 1. Increased tension in the systemic arteries; 2. Hypertrophy of the heart; 3. Hypertrophy of the arterioles. The paper concludes with a short sketch of the changes in the renal vessels, which the author regards as purely local and part of the connective tissue changes in which the vessels share, as shown by Friedländer and others.

#### THE COLLEGE OF PHYSICIANS AND THE GOVERNMENT MEDICAL BILL.

AT an important meeting of the Fellows of the College of Physicians, held on Tuesday last, for the purpose of considering the Bill, to which we elsewhere refer, the President made a very clear statement concerning the Bill, showing how objectionable were many of its features and how injurious it would be if passed into a law, not only to the interests of the College, but to the interests of the profession and the public. A special objection was made to the Bill, inasmuch as it would take away the privilege which the College has under its Charter and Act of Parliament, 32nd Henry VIII. chapter 40, of conferring a licence in both medicine and surgery. This is a privilege which the College is determined not to surrender. To do so would be to render more conspicuous than ever the absurdity of one body giving a licence in medicine and another body giving a licence in surgery, and thus compelling candidates to go from College to College to obtain a complete qualification. The College likewise objected to its being required to participate in the conjoint scheme for England, which would be made binding by Act of Parliament, whilst the Scotch and Irish bodies were allowed free permission to do as they pleased. Under such circumstances, the English authorities would not agree to persevere in carrying out a conjoint scheme, which is now complete, and which would secure entrance to the profession by a single portal in this country. The substitute for the conjoint scheme, namely, entire control over the regulations of the medical authorities by the Medical Council, was objected to on many grounds, but especially on the ground that the bodies which give the licences and qualifications would be altogether deprived of the control of the conditions under which such qualifications would be given. The College further objected to the roundabout way in which women would be admitted to practise under the Bill, and some of the objectors suggested that a much simpler method would be, if women were to be admitted at all, to have a separate and special examination for them, either under the control of the Government or of the Medical Council, together with a separate Register.

Other points were alluded to and objections made, but it was felt that these belonged rather perhaps to the province of the Medical Council than to that of the College of Physicians. On the whole, the Bill was regarded as very objectionable in its character, and not at all calculated to remedy or remove the evils which exist as regards the interest of the public or of the profession. The College was addressed by Dr. Paget, Dr. Quain, Dr. Barclay, and other Fellows; and it was resolved that the President, with a certain number of Fellows to be nominated by him, should be empowered to communicate with the Lord President of the Council, and ask him to receive a deputation on the subject.

#### PRISON DISCIPLINE AND DISEASES OF CONVICTS.

IN our issue of February 2nd, we offered some remarks upon the case, in its medical aspects, of Charles McCarthy, a Fenian prisoner, who, having been released from the Chatham Convict Prison on January 3rd, died, after attending a public meeting in Dublin, twelve days subsequently. It was alleged that the prisoner was, while in prison, improperly worked, lodged, and fed, and was neglected and otherwise maltreated, and that, consequently, his disease was either caused or aggravated and his death occasioned. At the time, the partisanship of some excited politicians was inclined to beg the question, or rather to demand the verdict, that McCarthy was subjected to special neglect and ill-treatment. Placing this idea aside, calmer minds might inquire whether, in common with his fellow-prisoners, this unfortunate man was subjected to a discipline of underfeeding and overwork, the tendency of which would be either to originate or to hurry to a fatal issue the diseased conditions of the heart and lungs of which he was the subject. By order of the Home Secretary, the case has been investigated by Sir James Ingham, chief magistrate at Bow Street, assisted by Dr. Henry Pitman, who inspected with him the cells and workrooms, heard the statements of the witnesses, and gave his opinion respecting them. The report of this inquiry does not very materially enlarge our knowledge of the case in its medical aspect. Upon this point, we have before us nothing but the statements, gathered from Sir James Ingham's report and other (newspaper) accounts, that the deceased was aged 44, and had been a prisoner for twelve years. His weight was greater when he left his last place of imprisonment than when he entered it, and it was a fair average weight for a man of his age and height. At a time not clearly specified, but which appears to have been previous to his imprisonment, he suffered from rheumatic fever, to which the origin of the heart-disease of which he died is attributed. In the winters of 1873 and 1874, he was treated in the prison hospital for bronchitis. In January 1875, it was first discovered that he was the subject of heart-disease; and in the month of June following, he had, to use the magistrate's words, "a severe attack". Periodical examination with the stethoscope showed that his heart-disease was not progressive. The books show that, although he was treated, medically, fifteen times in 1873, he did not complain once in 1876, and only twice in 1877. We have no statement of his precise outward condition of health on his release; but Mr. Owen, a surgeon whom he subsequently consulted, states that he was warned of the extreme danger of attending a public meeting in his then state of health, and raises a strong presumption that his death was hastened by the excitement of his reception in Dublin. It was found that the heart was fat or fatty and dilated, and that there was some pulmonary tuberculosis. The immediate cause of death appears to have been considerable pleuritic effusion.

In the early part of his imprisonment, McCarthy had occasionally to carry rather heavy weights; but as long ago as 1871, he was transferred to the tailor's shop, in order that he might have light work and protection from the weather. In October 1871 (if not before), directions were given that he should be treated as easily as possible con-

sistent with proper discipline. It is again to be remarked that the disease of the heart of which he died was first discovered in January 1875. It is stated that, "in addition to his employment in the tailor's shop, he had to take his share of ordinary duty once a week. It consisted in carrying, with the assistance of another man, ten yards and up two flights of twelve and thirteen steps respectively, a dinner-tray weighing about one hundred and four pounds; and in carrying, without help, a can of tea weighing about fifty pounds, for breakfast and supper, over the same distance. Once a month, he had to take his part in removing slops to a sink a few yards off upon the same landing". This was not, assuredly, proper work for a prisoner known to be the subject of heart-disease, and it is much to be regretted that the magistrate does not mention the date on which it was discontinued. It is elsewhere stated that, from October 1871 up to June 1876, "he was required, once a week, to carry a parcel weighing about twenty-one pounds from the tailor's shop to the stores (a distance of eighty yards) and he had to walk with this parcel to the height of seven feet by a gentle slope fifty feet in length". After June 19th, 1876, he did not carry anything at all.

There is nothing very terrible in the work here described, but all lifting and carrying ought to have been interdicted when heart-disease was discovered in January 1875; and, seeing that it must have been quite unnecessary, it appears to have been a pity that even such moderate labour as this should have been continued for nearly eighteen months. That this light work increased the severity of the heart-disease, or had anything whatever to do with hastening death, we do not for one moment believe; but we think it in every way advisable that, for his own sake and for the prevention of such rumours as occurred in this case, a prison-surgeon should positively forbid all hard labour immediately he decides that a prisoner is the subject of organic heart-disease.

Most professional readers of Sir J. Ingham's report will agree with us in concluding that McCarthy was neither starved, stifled, nor tormented to death, nor (unless he was allowed to carry the tray and can after 1875) that he was at all overworked. It appears to us very clear that, if this unfortunate man had not been the subject of excited political feeling, his case would never have been brought to the notice of the public and the profession.

---

THE Director-General of the Medical Department of the Navy, Sir Alexander Armstrong, K.C.B., has been appointed a magistrate for the County of Middlesex and the City and Liberty of Westminster.

WE are pleased to hear that the new form of infantry accoutrements (devised by Surgeon-Major Oliver) has met with such general approval that tenders have recently been issued for the equipment of two regiments in them, as a preliminary step towards their general introduction into the service.

WE are very glad to hear that another effort will be made shortly to induce the Council of the Royal Medical Benevolent College to abolish the objectionable method of canvassing for votes which is still in vogue in that charity for filling up the lists of those who receive its benefits. A memorial for this purpose is in course of signature; and those who desire to add their names to it should communicate with Mr. Jabez Hogg, 1, Bedford Square.

LORD ABERDARE presided at the annual meeting of the Charity Organisation Society on the 3rd instant, at which, upon the motion of Sir W. Gull, a resolution was passed declaring that the establishment and extension of provident dispensaries would be a most important means of developing self-reliance and improving the condition of the people, and the meeting accorded its support to the Society in its effort in that direction.

TYPHOID fever and dysentery prevail among the troops in King William's Town; ninety cases are at present in the Grey's Hospital.

THE attention of the Society of Apothecaries ought, we believe, to be directed, as a matter of discipline, to the extraordinary advertisement of one of their licentiates in Sunderland—Dr. G. A. Abrath, M.D. Heidelberg—in which, after a long rigmarole of introduction, he concludes a very unprofessional style of advertisement in the local papers by publishing at length his scale of charges. Dr. Abrath alleges in the advertisement that he is bound to do this in vindication of his professional character. If vindication of professional character is to assume such a form as this, it is difficult to understand what form the attack would assume, for certainly nothing could be more contrary to ordinary notions of professional propriety than the shape which the vindication takes.

WE mentioned a fortnight since that Dr. J. Burdon Sanderson and Mr. Callender, as members of the Hydrophobia Committee of the British Medical Association, had an opportunity afforded to them by Dr. Nicholls of Chelmsford of visiting with him a man suffering from hydrophobia, and arranging in consultation with him a method of treatment. We are glad to see it stated that this patient, who has been under treatment for three weeks at the Chelmsford Infirmary, has been discharged convalescent from that institution. We understand that Dr. Sanderson and Mr. Callender have also been invited by a medical man at Blackwater, Hampshire, to visit a patient in his charge suffering from hydrophobia, and availed themselves of that invitation last week. The case has ended fatally; and Dr. Gowers will report on the pathological conditions.

IN the last monthly report issued by Dr. Goldie, there is a somewhat graphic picture of the manner in which many of the lower classes live in Leeds. In a small court, which was not only overcrowded, but where some of the rooms were indecently occupied, many children were seen running about almost naked, the mothers admitting that they were too idle to dress them; and one boy, not six years old, was engaged in smoking a pipe. Dr. Goldie also reported on an outbreak of measles which had been spread by the infected children attending school and playing about the streets and courts. On expostulating with the mother of some of the patients about the exposure, she replied that her children's measles could do no one any harm, as they were so large. As few mothers consider measles a dangerous disease, they should be impressed with the danger to their own children, as well as to others, by premature exposure in schools or other public places.

WE call attention to a letter from Dr. Reuben J. Harvey, Professor in the Carmichael School of Medicine, concerning the teaching of physiology in Dublin. He describes an extraordinary state of things. It seems not a little remarkable that, coincidentally with the course taken by Trinity College, to which we last week referred, the Council of the College should have declined to accept a course of practical physiology to meet the requirements of physiological teaching. Such a refusal carries one back thirty years, to the state of things graphically described by Professor Ludwig at the opening of the physiological laboratory in Berlin. He referred to the pre-scientific period, when physiological teaching was a sort of theoretical annex of the anatomical course, and when it was understood to mean a certain number of verbal observations illustrated by diagrams. It is a curious commentary on the retrogressive course of which Dr. Harvey complains, that, in the accepted scheme of education drawn by the conjoint medical authorities for adoption by the Conjoint Board in England, not only is a course of practical physiology compulsorily substituted for the ordinary second course of theoretical physiology belonging to a past day, but the same practical courses are insisted upon as a part of the teaching of surgery and of medicine. Dr. Harvey's application to the Council of the Irish College is in itself so reasonable, and so entirely accordant with the necessities of the improved teaching of the present day,

that he may rest assured that he will in the end succeed in having it approved and accepted; and we can only counsel him to persevere until the majority of the Council become sufficiently enlightened to accept the views which are everywhere else prevailing.

#### HOSPITAL SATURDAY IN BIRMINGHAM.

THE sixth Hospital Saturday collection in Birmingham, made on the 30th ult., resulted in a total of £2,141, being £84 in excess of last year. The increase is attributed to the adoption of the system of small weekly contributions by the workpeople at various establishments.

#### PROSECUTION UNDER THE APOTHECARIES' ACT.

At the Pontefract County Court, before Mr. Serjeant Tindal Atkinson, judge, and a jury, a case of some importance was heard, the court being filled with medical gentlemen and others interested. The Apothecaries' Company, London, were the plaintiffs in an action brought against the defendant, Thomas Johnson, of Knottingley, who had practised as an apothecary, not having duly qualified and obtained a certificate. Mr. Bond, of Leeds, appeared for the Company, and Mr. Hall, of Wakefield, for defendant. Mr. Bond, in opening the case, said the defendant had formerly been an assistant to Mr. Bywater and Mr. Percival, of Knottingley, which latter he left in June 1876, and has since been practising, it was said, as an assistant to his brother, a surgeon, at Darlaston, Staffordshire. The action was brought under the twentieth section of the Apothecaries' Act, 1815, and had been brought not only to protect the duly qualified practitioners, but also the public. There were several cases, he submitted, where defendant had prescribed as an apothecary, and no surgeon had a right to prescribe in medical cases, but in surgical operations only. After hearing the evidence, the jury retired; and, on returning into court, gave a verdict for the plaintiffs for the sum of £5.

#### PUBLIC HEALTH IN ENGLAND IN THE FIRST QUARTER OF 1878.

THE Registrar-General's last weekly return affords the means for summarising the mortality statistics of the more than seven millions of persons living in twenty of the largest English towns for the first quarter of this year. It thus supplies a trustworthy basis for estimating the national health during the three months ending March last. In the twenty large towns dealt with in the Registrar-General's weekly return, the annual death-rate during the past quarter was equal to 25.2 per 1,000 persons living, against 26.2 and 24.2 in the corresponding periods of 1876 and 1877. The mortality from the seven principal zymotic diseases was at the annual rate of 3.7 per 1,000 in these towns; in the two preceding corresponding quarters, it was equal to 3.8 and 3.0 per 1,000. Whooping-cough was the most fatally prevalent zymotic disease during last quarter, and caused 2,438 deaths in these towns, against 2,019 and 1,063 in the first quarters of 1876 and 1877. Whooping-cough was especially epidemic in London, Plymouth, and Liverpool. The annual death-rate from all causes showed its usual wide variations in the twenty large towns during last quarter. While it did not exceed 17.6 in Portsmouth, 18.7 in Leicester, and 20.9 in Leeds, it ranged upwards in the other towns to 28.8 in Liverpool, 29.1 in Manchester, and 32.6 in Plymouth. Portsmouth and Plymouth, therefore, both dockyard towns on the south coast, show respectively the lowest and highest death-rate among the twenty large English towns during last quarter. Such a fact is not without its interest and importance to the student of public hygiene. It is true that the excessive death-rate in Plymouth was in great measure due to the fatal epidemic of whooping-cough, the mortality from which was equal to an annual rate of 5.5 per 1,000; but the disease was also somewhat fatally prevalent in Portsmouth, although there the death-rate resulting therefrom did not exceed 1.2 per 1,000. Why was the disease so much more fatal in Plymouth than in Portsmouth? Can the difference be referred to sanitary condition? The death-rate among infants under one year of age was during last quarter more than twice as high in Plymouth as in Portsmouth. Among the most noticeable features in the recent mortality statistics of our large towns may be

mentioned continued excessive death-rates in Manchester, which generally now exceed those in Liverpool; and the conspicuous reduction in the rates which prevail in Newcastle-upon-Tyne and Leeds. The improved sanitary condition of most of our largest towns, under the advice and superintendence of medical officers of health who are not engaged in private practice, but devote themselves entirely to public hygiene, is proved beyond all question by the declining rates of mortality. The mortality statistics of these twenty large towns, situated as they are in different parts of the country, afford the means for calculating approximately the national death-rate during the past quarter, which cannot be accurately determined until the publication of the Registrar-General's quarterly return on May 1st. Assuming that the death-rate in our largest towns bore last quarter the same proportion to that in the whole country which generally prevails at this season of the year, it may be calculated that the annual death-rate in England and Wales in the first three months of this year was equal to 23.3 per 1,000, which, although 1 per 1,000 above the exceptionally low rate that prevailed in the corresponding period of last year, was 0.7 lower than the average rate in the first quarters of the ten years 1868-77. The winter of 1877-8 was nearly as mild as that of 1876-7; but, in spite of the exceptionally high temperature of the greater part of January and February, the mortality in those months, especially among elderly persons, was unusually high, and the fatality of diseases of the respiratory organs was excessive. Judged by the returns from the twenty large towns, small-pox was remarkably quiescent throughout England and Wales, excepting only its epidemic prevalence in London and a few slight outbreaks of a distinctly local character. At the end of the quarter, unfortunately, the small-pox epidemic in London showed increasing proportions, and the fatality of whooping-cough was unprecedentedly severe.

#### OPHTHALMIA IN SCHOOLS.

IT is not always, and not perhaps often, that we are able to speak with satisfaction and applause of the prompt and judicious proceedings by boards of guardians in dealing with their sick charges. The Westminster Union Board of Guardians certainly deserve a meed of praise for the judicious promptitude with which they are taking steps to isolate and extinguish an endemic of purulent ophthalmia which has occurred in their schools on Wandsworth Common. We shall not refer to the circumstances under which this state of things originated, and by which it was allowed to extend. That is a subject on which we think the Board ought to make some inquiry, with a view to prevent the recurrence of that misfortune. Endemic purulent ophthalmia always implies defective sanitary arrangements, and its occurrence should always be the signal for careful inquiry and for the institution of remedial measures, not only with a view to cure, but also for the prevention of the recurrence of such outbreaks. The Guardians have, we believe, removed all infected children from the centre of infection to their infirmary in Poland Street, and have sanctioned the employment of the services of an ophthalmic specialist, whose advice will be taken, we trust, not only as to cure of existing patients, but also in reference to the circumstances under which the endemic originated and the means for preventing its recurrence.

#### THE SILENT SYSTEM IN PRISONS.

M. BURQ, in a communication to the Académie de Médecine of Paris, March 12th, 1878, states that, in 1838, Dr. Cornet wrote, in the *Annales d'Hygiène*, vol. xix, "Silence debilitates the digestive system, weakens the respiratory organs, and predisposes to phthisis". Some years later, Fourcaud maintained the same thesis, basing it on statistics which showed that, in certain central prisons where the cell-system was in operation, the mortality from phthisis amounted to half the general mortality; and even in some instances exceeded that limit, as at Poissy, where it was at the rate of 60 per cent. M. Burq has made a careful examination of official documents placed at his disposal by the French authorities, and arrives at the following results. On May 10th, 1839,

appeared a Ministerial decree, ordering the observance of the silent system in the central prisons. From that time, the death-rate, which had remained stationary for some years at about 6.25 per 100, rose progressively to 6.85, 7.95, 8.38, and finally to 9.95 per cent., notwithstanding the most praiseworthy efforts of the prison authorities to improve the diet and the hygienic condition of the prisoners. The Revolution of 1848 intervened; discipline was relaxed, the decree of 1839 became a dead letter, and the death-rate, which was 9.95 per cent. in 1847, fell to 6.96, then to 5.24 per cent., where it remained nearly stationary until the day when, after the *Coup d'Etat* in 1852, the law was again put in force. The death-rate again rose to 6.31 in 1853 to 7.01 in 1854, and during the whole time diseases of the respiratory organs were the cause of these oscillations. On the other hand, the mortality statistics of the agricultural penitentiary establishments in Corsica, where the silent system is not in force, show a general death-rate of 1 per cent. in excess of free life, and a death-rate of 6.5 per 100 from pulmonary phthisis, on the general death-rate, which is about a half less than is found in the non-criminal population of the same age. These figures lead M. Burq to the conclusion that May 10th, 1839, was a fatal date for penitentiary prisons, and that a remedy for the present state of things must be sought.

#### ARSENICAL POISONING IN MINING DISTRICTS.

AN action of great toxicological interest was recently brought by the owner of a valuable brood mare to recover £50 for the loss of the mare, the death of which had been, it was alleged, caused by arsenical fumes escaping from a chimney-stack belonging to the mine. The value of the mare was said to have considerably exceeded the £50 claimed, but this latter value had been put on it in order to bring the action in the County Court. The action was, at the defendant's instance, removed to the Supreme Court, and was tried at Bodmin before Sir J. F. Stephen and a special jury. According to the plaintiff's case, the mare, which had been accustomed to feed in a field in the neighbourhood of the defendant's mine, died with all the symptoms of arsenical poisoning. The evidence of Mr. S. T. Rowe, of Redruth, an operative chemist, was to the effect that he had found arsenic in the mare's entrails and in the herbage of the fields about; that the defendants raised tin and arsenic from their mines, and burnt the arsenic in furnaces which were so imperfect that a vast quantity of arsenic escaped and would spread over the plaintiff's field, which was but a short distance off. For the defence, a mass of evidence was called to show that the works were of the most perfect description; that no arsenic could escape beyond the merest trace; that the inhabitants of neighbouring houses drank water which drained off their roofs with no injurious effects, and no other animal in the neighbourhood had been poisoned. Chemists were called who stated that they had also examined the entrails of the mare, and found only a minute quantity of arsenic—in fact, no more than would be found in every man, woman, and child in the mining district. The jury found a verdict for the defendants.

#### NEGLECT OF VACCINATION.

AN inquest was held on Saturday last, by Dr. Hardwicke, Coroner for Central Middlesex, at the Islington coroner's court, on the body of Charlotte Rose Bell, aged 4, who died on the 27th ult. from confluent (black) small-pox, at 24, Albert Road, Upper Holloway. Joseph Atkinson Bell stated that he had four children, including the deceased. They had a short time since come up from the country, and the children were attacked with small-pox. They had not been vaccinated, as his wife and himself objected, being afraid that erysipelas would set in if improper lymph were used. The other children, aged eight, six, and three years, were seized first, and recovered. On the 14th instant, the deceased was feverish and a few spots appeared; Mr. Brooks, of Tollington Park, was called in, and attended her daily till her decease, when he gave a certificate of death from confluent small-pox. On taking the document to the registrar, that official asked him (witness)

several questions, which he, considering them out of place, did not answer. The registrar then refused to register the death, and informed him that probably an inquest would be held. He had not registered the birth of deceased, and he and his wife were alone responsible for the neglect in not having the children vaccinated. He had not of late joined any anti-vaccination society, but admitted that ten years ago he was interested in one. He had given notice of the death of deceased at the Vestry, and his house was being disinfected. Mr. R. W. T. Brooks was called to see deceased on March 14th, and found her suffering from confluent small-pox; he attended daily until death, when he gave a certificate, which was refused by the registrar. He had been told that the father of deceased objected to vaccination. He (witness) was of opinion that vaccination, in a large number of cases, prevented, and in others modified, attacks of small-pox; he was also of opinion that revaccination was nearly a perfect safeguard against fatality in small-pox. Mr. George Wight, of Liverpool Road, gave evidence of a case which he was attending of a lady at No. 18, Albert Road, in the vicinity of the house where deceased expired. She had contracted small-pox; and, being a very susceptible subject, he was of opinion that it had been contracted from an infected house in the neighbourhood. The jury, after a short deliberation, returned the following verdict: "That the deceased died from an attack of confluent small-pox, and that her life was endangered by the neglect of her father in not having her vaccinated, and his conduct deserves censure." A verdict of manslaughter would perhaps have been more to the point.

#### INFLUENCE OF M. PASTEUR'S DISCOVERIES ON THE PROGRESS OF SURGERY.

AT the meeting of the Paris Academy of Sciences, on March 11th, M. Sédillot spoke on this subject. He showed how the hypothesis of aerial germs afforded an explanation of phenomena which were perfectly well known, but of which the cause was in obscurity, and how, likewise, this hypothesis was verified by the application of wadding or carbolised dressings, which destroyed the germs, prevented their reaching the wound, or formed an obstacle to their multiplication. M. Sédillot cited the results obtained by Mr. Lister and by M. Guérin. He also noted that amongst the hopes raised by the application of M. Pasteur's discoveries may be reckoned the immediate union of bones in resections of joints, and their fibrous transformation without suppuration after amputation. It is, in fact, due to treatment in conformity with M. Pasteur's principles that M. Eug. Boeckel has been able to obtain four rapid cures of wounds resulting, two from amputations of the thigh, and two from excision of the mammary glands. M. Abadie, in reference to M. Sédillot's facts and theories, stated that at Mucaww'a, on the borders of the Red Sea, he had often met with that form of chronic ulcer which in those regions generally follows the least wound received below the knee, and is called the Yemen ulcer, from the district of Arabia where it was first observed. The inhabitants have a theory that, to get cured, the wound must remain open to the air. M. Abadie has had the opportunity of proving that this idea is well founded; and, if he be supported by any special observations, it must be concluded that the air of those regions does not contain any *microbes*—the generic name by which M. Sédillot designates microscopic aerial organisms.

#### SCOTLAND.

THERE were very heavy snow-storms in the north of Scotland at the beginning of this week. Many of the railway lines were blocked, and telegraphic communication was much interfered with.

THE directors of the Royal Infirmary of Glasgow, having resolved that no cases of cut-throat or patients afflicted with "delirium tremens" should be received into the institution, the Town Council have appointed a deputation, with a view of getting this resolution rescinded or modified.

THE Health Committee of the Glasgow Town Council are making arrangements for converting St. Mark's burying-ground of that city into an "ornamental open space".

AT the March meeting of the Faculty of Physicians and Surgeons of Glasgow, the resignation was announced of Dr. J. G. Fleming, as representative of the Faculty in the General Medical Council.

THE Medical, Law, and Theological Classes in the University of Edinburgh closed last Friday. The total number of students who have attended the University during the past session, has been about three hundred in excess of that recorded for any previous year.

THE death-rate of Edinburgh stood last week at 27 and the birth-rate at 36 per 1,000. No deaths from fever, diphtheria, or small-pox were recorded. The mortality from measles has fallen from 20 deaths to 8, all of which occurred in the Old Town.

THE Senatus Academicus of the University of Edinburgh have received a bequest of £2,000 by the late Dr. Andrew R. Cameron, of Richmond, New South Wales, "the proceeds of which are to be given in each and every year to the practitioner, a member of the medical profession, who shall be adjudged to have made the most valuable addition to practical therapeutics during the year preceding".

#### EDINEAIN, SKYE: THE GESTO HOSPITAL.

THIS neat and substantial, if unpretentious, building, the gift of the late Kenneth Macleod of Gestornish to the people of Skye, has been opened for the admission of patients, several of whom have already taken advantage of the benefits of the institution. The hospital is nicely situated in a sheltered spot underneath the hills, and facing an arm of the sea, where all the elements of a healthy atmosphere apparently abound.

#### THE GLASGOW MILK-SUPPLY.

A DEPUTATION from the Committee, recently appointed at a public meeting held in Glasgow, to consider what steps should be taken to secure a supply of pure milk for the city, waited recently on the Town Council. Among the members of the deputation were Dr. McCall Anderson and Dr. Donald Macleod. The spokesman of the deputation pointed out that the supply of pure milk was a subject next in importance to that of pure air and pure water. The present seemed a favourable opportunity for bringing the subject prominently to the front, as one hundred and sixty cases of typhoid fever had recently been traced to poisoned milk coming from a single dairy. Besides the Glasgow epidemic, there had been outbreaks of fever in London and Manchester traceable to milk-poisoning. While the deputation did not wish to dictate to the Corporation what measures should be taken to secure the end in view, they had been bound to submit some tangible scheme; and accordingly, Sheriff Spens had framed suggestions which would be laid before the Corporation Committee for consideration. Dr. McCall Anderson also spoke in favour of some measure, such as those suggested. He said that, beyond question, thousands of persons every year were seized with illness, and many of them died from infectious diseases communicated by means of poisoned milk. The Lord Provost, in reply, said that the Council recognised the importance of the subject, and already the Health Committee had been considering the matter. The Council would be glad to give the deputation every assistance in their power, in getting a Bill to lessen in measure the evils which the public were at present exposed to from contaminated milk.

### IRELAND.

AT the Wicklow Assizes last week, a proposition to abolish the County Infirmary was brought forward; but, as the majority of the grand jury expressed their disapproval, no further action was taken in the matter.

#### THE SMALL-POX EPIDEMIC.

WE regret to state that Dublin is still suffering severely from this preventable disease. Many cases of a virulent form have appeared, and the disease is spreading among the better circumstanced classes of the community. Valuable time has been irrevocably lost by local sanitary authorities in providing accommodation for small-pox patients and convalescents, and in the isolation of cases. After three weeks' inaction, a proposal was adopted by the Guardians of the South Dublin Union, that some sheds on the workhouse grounds should be used for small-pox patients and convalescents. These sheds, it would appear, are insufficiently isolated from the main building, which contains a large number of paupers. The medical officers of the Union protested most strongly against this dangerous proposal; and, after losing another week—a month having thus elapsed since the matter was brought prominently before the guardians—the objectionable resolution has been rescinded. The guardians have now resolved to enter into an arrangement with Cork Street Hospital, and, if necessary, with some other hospital, for the reception of small-pox patients, and to provide the necessary funds for getting the increased accommodation and attendance required.

#### OVARIOTOMY.

THE Master of the Rotunda Hospitals, Dr. Atthill, performed ovariectomy last week. The patient was a rather delicate-looking young woman aged 25, but the case appeared to be a favourable one for operation. There were no adhesions, and the cyst was removed, under the carbolic spray, without any difficulty. Unfavourable symptoms, however, set in the following day, and she died of hæmorrhage, about thirty hours after the operation.

#### THE COOMBE LYING-IN HOSPITAL.

HER Grace the Duchess of Marlborough visited this hospital last Saturday, and was conducted through the institution by the Master, Dr. Kidd, and other members of the medical staff. It will be remembered that the enlarged, and in great part newly built, hospital was reopened last May by the Lord-Lieutenant and the Duchess. Since Her Grace's visit on that occasion, the hospital has been in full working order, four hundred and eighteen women having been delivered in it, in addition to those admitted into the chronic wards. Her Grace expressed herself as being greatly pleased at the excellent order and evidences of good management she found in every department of the institution; and, on leaving, made a highly complimentary entry in the visitors' book.

#### ARMY MEDICAL SERVICE.

IN connection with the recent communications that have been made to the authorities of the medical schools by the late Secretary of State for War, the Royal College of Surgeons in Ireland have adopted a rather remarkable procedure. Being desirous of learning the actual state of feeling now existing in the Army Medical Service, relative to the unification and regimental systems respectively, the President and Council have considered that the best way of ascertaining the same would be by ballot. A voting-paper, therefore, having on it "the regimental system" and "the unification scheme", in separate columns, has been directed to all the officers of the department serving in the United Kingdom. The officer is requested "to put a + before whichever system he considers best", and return the voting-paper in an accompanying stamped envelope, with the address of the Secretary of the Royal College of Surgeons printed thereon. Should he also desire to offer any suggestions for the improvement of the Army Medical Service, or to point out any existing abuses in it, the Council of the College state that they will be glad to receive the same; pointing out that, as such information will be anonymous, it may be given unreservedly.

#### AN UNFORTUNATE ERROR.

GREAT excitement has been caused in Galway by an unfortunate mistake, attended with shocking circumstances. Two paupers having died in the workhouse, the relatives claimed the body of one, and the other corpse, being unclaimed, was given over to the medical school

connected with the Queen's College. In removing the remains at night, the wrong body was taken, and was dissected before the blunder was discovered. The relatives came to have the body of their kinsman buried, but only some fragments remained, which were put into a coffin and given to them. While the funeral was proceeding, it was remarked that the coffin was light, and the lid having been removed the truth was discovered. The daughter of the deceased, in the frenzy of her exasperation, took the remains in her apron and flung them at the gate of the workhouse. The chaplain had great difficulty in allaying the excitement of the people. Bishop M'Evilly, on learning the facts, prohibited the celebration of mass in the workhouse, but has been requested by Captain O'Hara, the chairman, to withdraw the interdict, an inquiry being promised.

#### PHYSIOLOGICAL TEACHING AT TRINITY COLLEGE, DUBLIN.

THE following memorial, petitioning the Board of Trinity College to reconsider their decision whereby they have refused to allow any place within the University to be registered under the Cruelties to Animals Act (39 and 40 Vict., chap. 77), has been circulated among the graduates of the higher medical and surgical degrees, and has received a large number of influential signatures in a few days.

"We, the undersigned Doctors in Medicine and Masters in Surgery of the University of Dublin, beg most respectfully to petition the Board of Trinity College to reconsider their decision of March 23rd, 1878, as to the question of registering certain places within the precincts of the University, under the Act 39 and 40 Vict., chap. 77. In support of our petition, we beg to state that—

"1. By the decision in question, all original research in the domain of experimental physiology, pathology, and therapeutics is absolutely prohibited. No professor can legally make the simplest observation on any living vertebrate, if the conditions to which the animal is subjected can be supposed to give the slightest pain. Considering the very strict provisions of the Act, and that, over and above these, the board would always have full power to make whatever regulations might be deemed advisable, we cannot but regard the decision as needlessly sweeping; and we are of opinion that it will not only debar the University from the performance of a most important duty, but that it will tend to cause clandestine experimentation.

"2. While most willing to comply with the provisions of the Act, which require that no painful experiment shall, under any circumstances, be shown to a class, we are of opinion that the demonstration of certain vital phenomena, such as can be shown only on the lower animals, is of paramount importance in the teaching of physiology; and physiology we consider to be the basis of medical education. Hence, as the decision of the board puts a complete stop to all such teaching, we cannot but regard it as highly detrimental to the educational powers of the University. The effect most certainly will be that students who are thus debarred from learning their profession scientifically in the University must go elsewhere, if they are to learn it scientifically at all.

"3. We are of opinion that the decision will have the effect of deterring competent and efficient men from coming forward to fill the professorships."

#### MEASLES AND VACCINATION.

AN outbreak of measles was reported last week at a meeting of the guardians of Swinford Union, by Dr. Blake, in the Kilmeeve portion of his district; and, in consequence, he believed that it would be unwise and dangerous to oblige a compliance with the provisions of the Compulsory Vaccination Act at present, as it would be calculated to spread the infection.

#### HEALTH OF BELFAST.

THE report of the Sanitary Committee brought before the Belfast Town Council, at their usual monthly meeting held last Monday, showed that, between February 27th and March 28th, ninety-seven cases of zymotic disease were reported by the medical officers of the nine sub sanitary districts, which included twenty-six cases of small-pox, all of which were removed to hospital; the houses where contagious diseases had occurred being thoroughly cleansed, fumigated, and purified. Eight fatal cases of small-pox were registered between

the 2nd and 22nd ult. The fatal cases of zymotic diseases were twelve less than in February, and the general death-rate was three per thousand lower than in that month. This decrease arose partly from the diminished mortality in fever, measles, and diarrhoea. The last case of small-pox which has been reported occurred on the 25th ult., so that it may fairly be assumed that the disease has been materially checked by the prompt steps taken in having the cases removed to hospital, the premises thoroughly cleansed, and the houses fumigated and whitewashed. In all cases where the bedding and rags of clothing could not be cleansed, they were burned.

#### SMALL-POX IN BELFAST.

AT a meeting of the Belfast Guardians last week, Dr. Seaton Reid reported that six cases of the disease had been admitted during the week, and five patients sent into quarantine. The disease does not appear to be increasing; at all events, the mortality has been but trifling. As regards vaccination, the Local Government Board have pointed out that, as small-pox is prevalent to some extent in the town, it is of the highest importance that every exertion should be made to have the provisions of the Compulsory Vaccination Act carried out as fully and effectually as possible.

#### SMALL-POX IN LIMERICK.

AT the Board of Guardians last week, it was stated that the Governors of St. John's Hospital would receive small-pox cases in the event of an epidemic, and have agreed to allow the guardians the Cholera Ward in that institution for £10 a year; the board to put it in proper repair. The matter is under consideration; but it is probable that, should it be necessary, the guardians will erect a new building close to the workhouse for the reception of small-pox patients, which will isolate the convalescent cases as well as those suffering from the disease.

#### RATHDOWN UNION.

AT a meeting of the guardians of this union on the 27th ult., a letter was read from the Local Government Board, urging upon them the necessity of paying due attention with regard to the erection of small-pox sheds in the workhouse grounds. It was, however, stated that there were only two small-pox patients in the isolated infirmary-wards at present, and that there was room for some eighteen others; so that there was no immediate necessity for going to the expense of erecting sheds as proposed.

#### FEE FOR CERTIFYING A LUNATIC.

AT a recent meeting of the Ballina Board of Guardians, an order on the board, signed by magistrates, to pay £2 to Dr. Mahon for examining a dangerous lunatic, was under consideration. The feeling of the guardians appeared to be that the fee was too high, one guinea being ample; and the board ordered the certificate to be returned to the magistrates, and the clerk was desired to state that they wished the justices would assess in such cases in proportion to the trouble and distance in each individual case, £2 being the maximum sum.

#### AN UNFOUNDED CHARGE.

AT a late meeting of the Westport Guardians, a communication was received from a Roman Catholic clergyman in reference to his recent complaint against the medical officer and sanitary officer of the Islandeady Dispensary District. The Committee of Management held a special meeting on February 4th, to consider the charges made, and they expressed unanimously their high opinion of Dr. Allman as medical officer, and declared their full approval of the manner in which the sanitary subofficer discharged his duties. The matter, however, was brought under the notice of the Local Government Board, and a formal inquiry demanded by the reverend gentleman, which was refused by the board, as they stated that they did not see what further object would be gained in a subject which had already received investigation at the hands both of the Board of Guardians of Westport Union and of the Committee of Management of the district.

## BRITISH MEDICAL ASSOCIATION.

## EXTRAORDINARY GENERAL MEETING.

AN extraordinary general meeting of the Association, called by requisition, was held at the Queen's Hotel, Birmingham, on the 2nd instant, at 3 P.M. Dr. EASON WILKINSON, President, occupied the Chair. The following members were present.

Agar, S. H., Esq., Henley-in-Arden; Anderson, Mrs. E. Garrett, M.D., London; Archer, J., Esq., Edgbaston, Birmingham; Archer, W. G., M.B., Birmingham; Arlidge, J. T., M.D., Newcastle, Staffordshire.

Baker, A., Esq., Birmingham; Barker, J., Esq., Coleshill; Bartlett, T. H., M.B., Birmingham; Bartolomé, M. M. De, M.B., Sheffield; Bassett, J., M.D., Birmingham; Bates, W., Esq., Birmingham; Batten, W. S., Esq., Bromsgrove; Bindley, P., M.B., Birmingham; Bodington, G., Esq., Sutton Coldfield; Bodington, G. F., M.D., Kingswinford; Borchardt, L., M.D., Manchester; Bracey, C. J., M.B., Birmingham; Bracey, W. A., Esq., Birmingham; Bradley, J. P., Esq., Birmingham; Brett, J., Esq., Birmingham.

Cameron, H. C., M.D., Glasgow; Carmichael, W., M.D., Edinburgh; Carpenter, A., M.D., Croydon; Carter, A. H., M.D., Birmingham; Chadwick, C., M.D., Tunbridge Wells; Chavasse, T. F., M.B., Birmingham; Clark, J., M.D., Lichfield; Clayton, W., Esq., Accrington; Clibborn, W., M.B., Birmingham; Cook, F., M.D., Cheltenham; Cornwall, J., Esq., Fairford.

Day, H., M.D., Stafford; Donovan, W., Esq., Whitwick; Dunn, G. P., Esq., Hales Owen.

Eales, H., Esq., Birmingham; Eastwood, J. W., M.D., Darlington; Edginton, R. W., M.D., Birmingham; Elkington, G., Esq., Edgbaston, Birmingham.

Falconer, R. W., M.D., Bath; Fausset, H. J., M.B., Tamworth; Flinn, D. E., Esq., Brownhills; Foster, B., M.D., Birmingham; Fox, E. Long, M.D., Clifton; Freer, A., Esq., Stourbridge.

Gamgee, S., Esq., Birmingham; Garman, J. C., Esq., Wednesbury; Goulder, F. S., Esq., Dudley; Gray, F. J., Esq., Rugeley; Grigg, W. C., M.D., London; Guthrie, G., M.B., Lichfield.

Hadley, J. J., Esq., Tamworth; Harmar, J., Esq., Birmingham; Hartshorne, F. H., Esq., Bursley; Hayes, J., Esq., Stoke; Henry, A., M.D., London; Hex, H., Esq., Birmingham; Hickinbotham, J., M.D., Birmingham; Hiron, J. H., Esq., Studley; Holloway, G., Esq., Cannock; Holman, C., M.D., Reigate; Humphreys, J. R., Esq., Shrewsbury; Hunt, B., M.D., Birmingham; Hunt, J., Esq., Birmingham; Husband, W. D., Esq., York.

Jackson, A., Esq., Sheffield; Jackson, V., Esq., Wolverhampton; Johnston, J., M.B., Birmingham; Jolly, R., M.D., Birmingham; Jones, A., Esq., Dudley; Jones, G., Esq., Birmingham.

Kelty, P. M., Esq., Walsall; Ker, H. R., Esq., Dudley; Keyworth, J. A., M.D., Aston.

Lee-Strathy, F. R., M.D., Birmingham; Legge, W., Esq., Derby; Lewis, H., M.D., Folkestone; Lister, J., Esq., London; Lloyd, G. J., Esq., Birmingham; Lowe, H. G., Esq., Birmingham; Luce, J. J., M.D., Stratford-on-Avon; Lund, E., Esq., Manchester.

Machin, G. S., Esq., Birmingham; McVeagh, D., Esq., Coventry; Malet, H., M.B., Birmingham; Malins, E., M.D., Birmingham; Manby, F. E., Esq., Wolverhampton; Manley, J., Esq., West Bromwich; Marriott, C., Esq., Leamington; Mason, F., Esq., Bath; May, B., Esq., Birmingham; Monckton, D. H., M.D., Rugeley; Moore, M., Esq., Coventry.

Napper, A., Esq., Cranleigh; Nason, R. D., Esq., Nuneaton; Nicholson, R. H. B., Esq., Hull; Newham, C. S., Esq., Wolverhampton.

Oakes, A., Esq., Birmingham; Owen, L. H., Esq., Birmingham.

Palmer, J. H., Esq., Birmingham; Parsons, C., M.D., Dover; Pemberton, O., Esq., Birmingham; Prosser, R., Esq., Bromsgrove.

Rickards, E., M.B., Birmingham; Roberts, E., M.D., Eastbourne; Rogers, J., M.D., London; Rowland, H. M., M.D., Malvern Wells; Russell, J., M.D., Birmingham.

Saundby, H., M.D., Birmingham; Savage, T., M.D., Birmingham; Sawyer, J., M.D., Birmingham; Scurrah, J. D., M.D., Birmingham; Sharp, J. H., Esq., Walsall; Shuttleworth, G. E., M.D., Lancaster; Skeate, Edwin, Esq., Bath; Smith, R., Esq., Birmingham; Smith, S. J., M.D., Bilston; Snell, Simon, Esq., Sheffield; Solomon, J. V., Esq., Birmingham; Spanton, W. D., Esq., Hanley, Staffordshire; Sproston, W. H., Esq., Birmingham; Sutfield, C. R., Esq., Birmingham.

Tait, L., Esq., Birmingham; Terry, H., Esq., Northampton; Thomas, H. W., Esq., Birmingham; Thompson, J., M.D., Leamington; Tibbitts, J., M.D., Warwick; Totherick, J. Y., M.D., Wolverhampton.

Underhill, T., M.D., West Bromwich.

Vawdrey, T. G., Esq., Handsworth.

Wade, W. F., M.B., Birmingham; Waters, E., M.D., Chester; Welch, J. B., M.B., Birmingham; West, J. F., Esq., Birmingham; Weston, G. F., Esq., Stafford; Whitcombe, W. P., Esq., Birmingham; Wilders, J. St. S., Esq., Birmingham; Wilkinson, M. A. E., M.D., Manchester; Williams, T. W., Esq., Birmingham; Wilson, H. C., M.D., Birmingham; Wise, R. S., M.D., Banbury; Wood, J., M.B., Birmingham; Wright, M. H., Esq., Birmingham.

Yates, G., Esq., Birmingham.

The SECRETARY (MR. FRANCIS FOWKE) read the notice in the JOURNAL convening the meeting; and letters in excuse of absence were read from several members of Council. Dr. Waters, on behalf of Dr. A. P. Stewart, and Mr. A. Baker, on behalf of Mr. Wheelhouse, gave reasons for their not being present; the former in consequence of illness, the latter because of an important legal appointment.

## THE REPORTS OF PROCEEDINGS OF COMMITTEE OF COUNCIL.

Dr. GRIGG proposed the first of the resolutions given in the requisition calling the meeting. Before doing so, he said that, in order to avoid repetition and digression, and to try to do justice to the rather complicated subjects which he had to bring before the meeting, he had reduced to writing what he had to say on the different points, and with their permission would read it. Before performing the duty which was incumbent upon him of moving the resolutions included in the requisition to consider which the meeting was summoned, he had, at the request of two eminent members of the Association, Dr. Barnes and Dr. Quain, to read letters which they had addressed to him for the purpose of being communicated to the meeting.

Printed copies of the letters were handed to the members present; and that of Dr. Quain was read. On Dr. Grigg's proceeding to read the letter of Dr. Barnes,

Dr. A. CARPENTER rose to order. While willing to give to Dr. Grigg the fullest liberty of expounding his views, it could not be held that the meeting should hear Dr. Grigg read the written speeches of his friends who had not come. If Dr. Grigg would address himself to the subject of his resolution, the meeting would give him a fair hearing. [Cheers.]

Dr. GRIGG bowed to the view of the meeting thus expressed, and refrained from reading the letter of Dr. Barnes. He moved:

"That this meeting is of opinion that the Reports of the Proceedings of the Committee of Council should be published in as complete and intelligible a form as is consistent with the conduct of business; and that in no case should important resolutions affecting the general interests of the Association be omitted."

In stating the reasons which he thought the meeting might properly consider as conclusive in support of that resolution, he said that the proposition seemed self-evidently correct. It was, however, negatived at the last meeting of Committee of Council at which he moved the resolution. He could but hope that, having had further time for consideration, his colleagues in the Committee of Council would vote as unanimously in favour of the resolution at this meeting as they voted unanimously against it on March 13th. It was perhaps, however, proper to show why he thought it necessary to pass such a resolution at all. Had the Proceedings of the Committee of Council been published adequately? Take, for instance, the Reports of Proceedings at the last two meetings of Committee of Council, officially supplied for publication in the JOURNAL. Dr. Falconer had written to the JOURNAL that, if Dr. Grigg had attended the meeting of October 10th (to which he was never summoned), he would have known of the intention to take a shop and premises in the Strand, and to make an outlay on them, and to undertake printing; this having been fully discussed then, and decided upon in principle. He had read the published Report of Proceedings in the JOURNAL. In the first place, it was not published at all till six weeks after date; and, when published, it contained positively no reference at all to this highly important business, although it involved an expenditure of about £2,000 at least, and constitutes a new departure. He thought that, to call any such report a "Report of Proceedings" was an absurdity. All of the other business transacted, and which was reported, was mere routine—mere child's play—to this. Such a report was "the play of *Hamlet* without the Prince of Denmark." So with the Report of Proceedings, which was published in reference to the meeting in January. At that meeting of Committee of Council, it was definitely ordered that the seal of the Association should be affixed to the lease of the shop in the Strand. This was published. But it was also ordered that an expenditure of £1,000 be made on the repairs of the premises, and a further expenditure, which would probably amount to more than another £1,000, on plant and fittings. Well, this report also was not published till more than a month after date; and, when it did appear, all reference to the authorised expenditure of £1,000 and the projected expenditure of another £1,000 was again omitted. [Interruption.] These omissions were not accidental, for, first, he was forbidden by the General Secretary to communicate the facts to his Branch; secondly, when he publicly asked the President of Council to correct the omissions in the JOURNAL (which he expected would readily be done), then, as all knew, the President declined to do so; thirdly, that refusal to repair these omissions was subsequently approved by a deliberate vote of the Committee of Council. In fact, except from the information which his letters in the JOURNAL conveyed, the members had had no inkling of the fact that £2,000 of their money was to be spent in this way; and, up to this time, no official notification had been made of it, and the members had no cognisance of it except from himself. [Hear, hear.] There were other important omissions, to which he had referred in the letters which he had published in the JOURNAL on the subject; but to these, for the

sake of brevity, he should not refer. It would be seen that he did not ask for the publication of anything more than a fair and adequate report of the proceedings of Committee of Council. [*Hear, hear.*] Of course, minor details, routine payments, and private details were not what he spoke of; but, in the words of the resolution already adopted by the Council of the Metropolitan Counties Branch, and approved of by nearly 2,000 members of the Association, he moved:

"That this meeting is of opinion that the Reports of the Proceedings of the Committee of Council should be published in as complete and intelligible a form as is consistent with the conduct of business; and that in no case should important resolutions affecting the general interests of the Association be omitted."

Dr. JOSEPH ROGERS asked the President if, in the case of his seconding the resolution *sub silentio*, he would be shut out from speaking subsequently? [*Cries of "Certainly not!"*]

The PRESIDENT ruled that Dr. Rogers or any member who seconded a resolution in silence could speak subsequently.

Dr. ROGERS thanked the President, and seconded the resolution proposed by Dr. Grigg.

Mr. SAMPSON GAMGEE (President of the Birmingham and Midland Counties Branch) said he had taken upon himself to stand before the meeting to press the view that it was necessary for the proper and successful conduct of the Association, that the question of the publication of reports of proceedings in the Committee of Council should altogether be left to the discretion of the Committee of Council. [*Cheers.*] He had to appeal to the sympathy of the meeting in moving an amendment to the resolution proposed by Dr. Grigg. He appealed to their sympathy in taking this course, for he had not had the opportunity—not having the fortune to be a metropolitan member—of a long and intimate acquaintance with the mover of the resolution, though he had had a long and intimate acquaintance with the affairs of the Association—[*hear, hear*—]—and the members would see how ingeniously Dr. Grigg had stated his case, how he had elaborated his details, how deep had been his inquiry, how well he had marshalled his facts, how great had been his deliberation, and the speaker hinted that the meeting would be as kind to him under the obviously disadvantageous circumstances in which he should labour in opposing the resolution thus placed before those present representing the Association. He objected to the resolution on its merits. The first part of it was of no very serious import either one way or the other, and this he should, with no want of respect to the mover—for it was a mere truism to say "that the reports of the proceedings"—those which the Committee of Council considered might be published—"should be published in as complete and intelligible a form as is consistent with the conduct of business". That was stating a truism to which all members might fairly assent without any violence to their feelings—[*a laugh*—]—and in saying this he begged to congratulate Dr. Grigg upon the skill with which the resolutions were drawn. He hoped that he should have an opportunity of becoming better acquainted with Dr. Grigg, so struck was the speaker with admiration at the skill with which he had drawn up his case—with the ingenuous, not to say ingenious way, in which he had put his case, positively omitting no point whatever. It would be quite impossible for any body of men to do business if their hands were to be tied, as it was proposed to tie the hands of the Committee of Council in the second part of the first resolution, to which members must give their special attention. [*Hear, hear.*] What would the members of the Association in their individual capacities say if their bankers were bound to publish all their proceedings? how would business men care to have all their transactions published for the benefit of their rivals in business? [*Hear, hear, and cheers.*] It was often necessary to hold over in the Committee of Council resolutions, and this in the private interests of the Association; and it was often expedient, in the same interests, that resolutions should not be published at all. [*Cheers.*] The members must leave such matters in the hands and at the discretion of the governing body, and if they had confidence in that governing body they would do so. He also objected to the resolution in regard to its terms, for if it should be carried it would be a declaration of alienation of confidence in the Committee of Council; and he contended that if the Association had men to conduct their business they must have confidence in them. [*Cheers.*] The laws of the Association said that the business was to be vested in the Committee of Council; that might be right or it might be wrong; but he was not aware that the profession and the Association had protested against that law. [*Cheers.*] He himself was one who, in bygone days, thought that the Committee of Council had too much power, but now, if the Committee of Council should advise that greater extension should be given it, he should congratulate the Association, because he thought it was a wise course to educate as many as possible in the business of governing. [*Cheers.*]

The meeting at Birmingham in 1856 gave full powers to the Committee of Council, and how had they exercised it? Well, in 1858, the Association had 2,000 members and £800 of debt; and who then in 1858 would have predicted that in 1878 the Association would have 7,000 members, would have given £400 in the year for scientific grants, would have had a JOURNAL of the present character, and would have had a capital sum of its own invested? [*Cheers.*] There was present Dr. Falconer, who used to manage the finances of the Association when it had no money at all. [*Laughter and cheers.*] There were very few members then who were inclined to go in and share the responsibilities of the Committee of Council. Now, however, it seemed as if there were many candidates desiring to share the honours which the Committee of Council had won. [*Hear, hear.*] He maintained that the confidence which had so long been given to the Committee of Council, which had been given to them when there was no capital, should be given now they had accumulated capital; and that the Association should be that professional brotherhood, working for each other's good, which Sir Charles Hastings, its founder, designed it should be. To limit the confidence which the Association had in the Committee of Council would be to thwart those endeavours which had hitherto been exercised so much to the advantage of the Association. [*Cheers.*] If this confidence of the Association should be thus limited, who would undertake the duties now discharged by the Committee of Council? Would commercial men, who were directors of banks or other undertakings, submit to have their governing actions thus controlled? [*Hear, hear.*] He should like to ask if the Committee of Council had any fees for their discharge of duties for the Association? [*Laughter.*] and the members of the Committee of Council present answered emphatically in the negative. Well, then, if men who had fees would refuse a position if there was an implied want of trust, how much more would gentlemen, who received no fees, feel disinclined to carry on the business of the Association under the like circumstances. [*Hear, hear, and cheers.*] He apologised for using an offensive word to professional ears—the word "business". [*Laughter.*] His excuse must be that it was a word much used in that town. A large buyer of coals in that town had his bills sent in "Mr. So-and-so to the Earl of Dudley". [*Laughter.*] One peer of the realm, who had marriage connection with the reigning Royal family, had also a son in a "tea-house"—but no doubt the metropolitan members of the Association, who knew, of course, all about the great city, could correct him if he were wrong—and these facts would show that he spoke of "business" in respectable company. In sober seriousness, the profession must not seem so to object to "business". The day when the members of the profession were looked up to as gods had passed—never to return; and the profession would have to appeal to the sympathy of their fellow-men by an intelligent discharge of their business duties. [*Hear.*] The manner of Dr. Grigg's speech had made him feel that he had not heard sufficient hitherto of Dr. Grigg; but he confessed he desired to see more of the Committee of Council's management, but he did not want to limit it. [*Hear, hear.*] There was particularly good reason why the Association should give its support to the Committee of Council at this time. It was twenty years ago since the passing of the Medical Act; and now, in 1878, Parliament was on the eve of legislation again. There were many important points in the Bill, and whether they became law would depend upon the Association, through the action of the Committee of Council. The Act of 1858, whatever might be its imperfections, was brought about by the Association in face of the opposition of some most important bodies. Now, in this year of legislation, it would be most unwise, to say nothing of the ingratitude of such a proceeding, to do anything which would seem like a limitation of the confidence in the Committee of Council, who gave the Association so much gratuitous labour. [*Cheers.*] He moved, as an amendment: "That it is necessary, for the successful transaction of the business of the Association, that the publication of reports of meetings of the Committee of Council should be left to the discretion of the Committee of Council."

Mr. WATKIN WILLIAMS, in seconding the amendment, said it gave him much pleasure in assisting to defend the action and privileges of the Committee of Council. He was not new to the business of the Association, and he was sure that it would be a fatal blow to the Association if the Committee of Council were to be hampered in respect to what they should or should not publish of their proceedings. [*Hear, hear.*] As Dr. Grigg's resolution stood, if carried, it would render it necessary upon the Committee of Council to publish all its business transactions; and, as had been said, this would be altogether contrary to prudence. The question was, Who should be the judge of what was to be published? And he held that, as the Association had grown from a few hundreds to be an Association of five thousand or six thousand members, and in a flourishing condition, the work could not

have been badly managed; and that, therefore, those who had conducted its affairs hitherto to this success were the best in which its affairs could still be left. [*Cheers.*] All that was necessary to say upon the subject had been so well put by Mr. Gamgee, that it would only be gilding refined gold to add to his words; but it must be urged that, if the Association were to continue to grow in *status*, numbers, and importance, it must change with the times, by going into the market where all men went who had to do with newspapers, and come face to face with those with whom they desired to do business—just as men desiring to trade with gunsmiths came to Birmingham. He knew nothing about the house in the Strand; but he had confidence that the Committee of Council would act honestly and fairly. [*Cheers.*] He did not say that they had never made a mistake, nor did he say they never would; but he said that fewer mistakes had been made by the Committee of Council than might have been expected, and he could give them the fullest confidence that, if any mistake should be made, it would not be because they were lax, or for the want of giving the subjects their best consideration. [*Cheers.*]

Dr. JOSEPH ROGERS said he had listened to the fervid eloquence of Mr. Gamgee, but had failed to catch much solid argument in that eloquence against the motion. Mr. Gamgee might be congratulated upon the fact that, if he stood only in the position of a "raw recruit", he had reached the head of his profession, and had so marshalled his views as to be worthy of promotion to the rank of a general officer. [*Laughter and cheers.*] Mr. Gamgee had addressed a very sympathetic audience, an audience in favour of his views. It was certainly a remarkable move to call the special meeting in Birmingham—it was more ingenious than ingenuous. Dr. Grigg had two thousand answers in support of his view that the house in the Strand should not be taken, many of the metropolitan members being amongst the number. [*Cries of "Question", "Ex parte statement", "Order", and other interruptions.*] When Dr. Grigg sent those circular letters, he appealed to unbiassed minds, by minds not to be swayed by eloquence like that of Mr. Gamgee. [*Cries of "Question".*] As to the action of the Committee of Council in regard to the house in the Strand. On October 10th, when it was first decided to take the house—

Dr. WADE rose to order. The question of the house was in the second resolution, and not in the first, then before the meeting. [*Hear, hear.*]

Dr. DAY said that Mr. Williams had not been called to order in his reference to the same subject.

Dr. ROGERS went on to say that the meeting would not have been called at Birmingham if it had not been for a purpose. [*Interruption.*]

Mr. WILLIAMS said that it had been the custom to call the meetings at Birmingham for many years.

Mr. A. BAKER believed that every special general meeting for the last fifteen years had been called at Birmingham.

Dr. ROGERS, proceeding, protested against attempts being made to shut out what he had to say. He did not want to make an attack on the Committee of Council; he did not say that the contemplated expenditure should not be made; but he maintained that, when it was contemplated to make so great an outlay, a general meeting should have been called. He knew that certain things in business matters ought to be kept back; but, when so large an amount of funds was intended to be sunk at once, it was felt by some that the Committee of Council had been led into a mistake.

Dr. EASTWOOD objected that the speech of Dr. Rogers did not bear upon the resolution before the meeting.

Mr. HUSBAND said that, if Dr. Rogers could show that something was being kept back by the Committee of Council which ought to have been made known, he had a right to do so; but he had no right at this stage to enter into the question of the propriety of taking these premises.

Dr. ROGERS said that the Committee of Council should have made their proposal to the whole body of their constituents. [*"So it was".*] Yes, six weeks after in one instance, and two months after in the other. He simply said that they were guilty of an imprudence, and one which he protested against.

A MEMBER asked if the Committee of Council, in what they had done, had exceeded their powers; and a reply in the negative was given.

Mr. HUSBAND said that, when gentlemen came to a meeting prepared to make charges, they should be very careful as to what they stated. Dr. Rogers, with the characteristic looseness of Dr. Grigg, had said that in October the Committee of Council determined upon the course they had adopted, when they had not determined upon any course at all. Dr. Rogers had spoken of the preconceived opinions of that meeting; but what was wanted was not any preconceived opinions upon the part of anyone, but a fair judgment as to the unfair attack

made upon the Committee of Council. He had facts before him which would exculpate the Committee of Council from all the charges made. In October—to give the facts—a report was made, or, rather, the subject was considered of taking premises; and this was the first time it was entered upon. It was not then determined upon. No resolution whatever was then passed. [*Hear, hear.*] The Committee of Council said: "This is a matter which requires grave and careful consideration." [*Hear.*] They said, with regard to the present offices, "We must get out of here; we are compelled to move."

A MEMBER rose to order. One question must not be mixed up with the other; and Mr. Husband was entering upon the second subject—the taking of the house. The meeting ought to be kept to the one resolution and to the amendment.

Mr. HUSBAND thought he must have been misunderstood, for he was keeping to the first question; he was not defending, then, the taking of the house, but was only showing that the Committee of Council had not suppressed anything. [*Hear, hear.*] He was speaking strictly to the purpose before the meeting, showing that the Committee of Council, at the time referred to, had nothing to conceal, for nothing was done, and the taking of the premises was another question altogether. As he was saying when interrupted, on the 10th of October last the Committee of Council considered the subject for the first time. They appointed a subcommittee, who reported to them, and it was not until the 9th of January that the lease was determined to be taken. There was some accidental delay in the arrangements, but when this delay was remedied the matter was published, so it was unjust to say that there had been any suppression. [*Hear, hear.*] As to the statement of expenditure upon the premises, there had not been a farthing yet expended, and nothing had been done but to take the building. If the Committee of Council had not taken it when they did, they would have lost it, and the action was as quickly as possible reported in the JOURNAL.

Dr. WADE said that the confusion which had arisen was owing to Dr. Grigg having put the cart before the horse in discussing a matter of secondary importance first, and it was almost impossible to touch upon one subject without touching upon the other. As to the charges of a "move" in regard to the meeting being called at Birmingham, the fact was that all the special meetings were called there, and he hoped that the result of this meeting would be a warning to members not to readily, so readily as they had in this case, sign requisitions for special general meetings. [*Hear, hear.*] Birmingham was the most suitable place for a meeting, for it was impossible for provincial men to come up to London and return in a day, whilst the majority of members could come to Birmingham and return in a day. [*Hear.*] Besides, in London there was an organised band for certain purposes, and he should be entirely opposed to a meeting to consider a requisition being held in a place where that requisition originated. [*Hear, hear.*]

Dr. GRIGG, in reply, said that, if Mr. Gamgee did not recognise him, he had pleasure in recognising Mr. Gamgee as an old and valued teacher. He complimented him on the energy and ability of his advocacy. He quite agreed that only suitable details should be published, and no minor matters. But the recent practice had been, in the official reports furnished to the JOURNAL, to omit amendments, and to omit reference to reports of Subcommittees. Now in this, more perhaps than most other Committees, the most important business was referred to and transacted by Subcommittees; and their reports, when adopted, constituted the most important parts of the proceedings, and those most necessary to be made known. His resolution only asked for a convenient and adequate report of proceedings. It could not be contended that the reports to which he referred were adequate or reasonable. The resolution seemed to be one which all parties who wished well to the Association should be willing and even eager to adopt.

A MEMBER asked whether, if the motion should be carried, the Committee of Council would take the vote as one of censure.

A chorus of voices responded, "Certainly".

Dr. GRIGG said that such was not his meaning.

Dr. BORCHARDT rejoined that in that case Dr. Grigg's words had not borne out his meaning.

The amendment was then put to the meeting and the great majority voted for it. "On the contrary" showed some ten hands. The amendment was then put as a substantive resolution, and the great majority voted for it, five hands only being held up against it. The amendment, thus taken as a substantive resolution, was declared carried, amid loud cheers.

THE NEW OFFICES OF THE ASSOCIATION.

Dr. GRIGG said: I have now to move the second resolution which stands on the paper. It is—"That this meeting desires to express its opinion that, in the selection of a house for the Association, it is desirable that the Council, Committee, and waiting-rooms should be separate from the printing and publishing offices". There are only two main grounds on which a scheme such as that the Council have in hand can be supported. The first would be that it is the best thing which can be done for the business interests of the Association; and the second is, that it would advance the professional interests of the Association. I will take first the business interests. The scheme to which the seal of the Association has been set involves, as does not appear in the reports of the Proceedings of the Committee of Council, but as the fact is, not only the renting of a shop and house in the Strand at £320 a year, on a lease of twenty-one years, but also the expenditure on these premises of a capital sum of £1,000 in repairs, and of an amount estimated at least as much as about £500 for fittings, and £500 at least, probably more, for printer's plant, together with a loss of nine months' rent, which means an expenditure of nearly £300 more, making a grand total of £2,300. Now, the avowed reason set forth in the recently published statement of the Committee of Council on this subject is, that such a proceeding will conduce first of all to a considerable economy in printing, and will further increase the income from advertisements. I have found no small difficulty in checking the calculations upon which this estimate is based, because the President of Council, Dr. Falconer, thought it right to instruct the General Secretary not to give me the detailed information which I sought, with the object to put before this meeting a perfectly authentic criticism of these estimates, in order that the basis of a fair decision might be obtained. I have, notwithstanding, enough information to enable me to put before you figures which will help us all to judge for ourselves. In the first place, how is the economy to be realised? It is to be realised, we are told, by the Association undertaking for itself what is technically known as the composition of the JOURNAL, that is, the setting it in type. When this subject was last discussed at the Committee of Council, I heard mixed up with it a good deal about savings which had been effected by purchasing our own paper, and savings which had been effected by purchasing our own stamps, and others which will still be effected by contracting for what is known as our own steam "machining", that is, the printing of the JOURNAL—a distinct thing from the composition. All these are, however, not to the point. They all arise from the fact that for some years the increasing income from the larger circulation, and consequent improvement in advertising income, has enabled us to pay cash for our paper, and contract direct for it, instead of having to let Mr. Richards buy it for us, on the strength of his credit, and charge us a profit on it, taking payment from us for it, at such times and in such a manner as we were able to make payments. Of course our earlier struggling years of impecuniosity compelled us, like many other people, to buy in a dear market, and involved a waste of money. As ready money purchasers, we have of late years been able to save that margin of profit, which was formerly impossible while we were buying on credit. (*Hear, hear.*) I really do not know, and have not been able to learn, why we have omitted for the last few years to save the like margin of profit which would have been realised if we had contracted for our own machining. So far as I can make out, there is no reason for it; it ought to have been done two or three years ago; and should be done at once. We are and have been throwing away, according to the General Secretary's calculation (no doubt on good grounds), not far short of £200 a-year by not doing it. The economy, however, now held up before our eyes is to be realised solely in the composition, by employing our own compositors, instead of contracting with a printer. Now I have seen and checked the rough calculations of the Secretary upon which this supposed economy is based, and by which the Committee of Council, I regret to say, have been misled. It was stated at the last meeting of the Committee of Council, and may possibly be stated again here to-day, that that economy would amount to between £900 and a £1,000 a-year. That statement is *prima facie* incredible, if not ridiculous, when we remember that the total cost of composition for the JOURNAL is only £1,900 a-year. It amounts to saying that we have been over-paying our present printer to the extent of £900 on an annual bill of £1,900—giving him a net profit of 90 per cent. on the composition of the JOURNAL. Such a statement would involve a profound reflection on the business management of the Association, as well as a great and most utterly unfounded reflection against our present printer—a man of the highest honour, and to whom, for a large part of twenty-five years, we have been much indebted, as Dr. Stewart could tell you, for rendering it possible even to maintain the very existence of the Association. At one period, the Association was indebted

to him above £2,500. It is well known that 12 per cent. is considered a fair printer's profit in contract work, for time and capital. Moreover, it has frequently been ascertained that Mr. Richards' contract price for composition of the JOURNAL was moderate, and even cheap. As a matter of fact, there has been no such overcharge, there is no such economy realisable; and the whole estimate is, I have convinced myself, by looking at it, and as you will convince yourselves in a few minutes, delusive and fallacious. The estimate which the Secretary has put before the Committee as promising these profits is roughly this. The actual cost of composition, as paid to Mr. Richards at the present for the JOURNAL is, *per annum*, about £1,900. Now the cost of wages of compositors, and of the services of one reader, if we were to employ our own men, would be £1,150; add 15 per cent. for replacing plant, say £75 *per annum*, and deduct this sum from that now paid in gross for composition, and the balance is £675; and this difference has been gravely put forward as a net realisable economy. A further saving of £200 a-year is calculated on machining; but that—even if the calculation be correct, which it is not—we can save, without moving, by making our own contract with the machiner. Such a calculation as the above is, I may be pardoned for saying, really childish, and would be amusing if the matter were not so serious. If the JOURNAL were to be composed in the street—if there were no cost for rent, repairs, rates, taxes, gas, fire, water, insurance, extra cost of house-cleaning and caretaking, interest, and replacement of expended capital, wear and tear of stock, or none of those minor costs which in the conduct of every business have to be added to mere wages in order to estimate what production costs, then such an estimate would be allowable. But it is obvious that all these things have to be included in our estimate, and we are going to pay very heavily indeed for the rent of our printing and publishing shop and premises. It is obvious, therefore, that the calculation of profit must be corrected by such additions of expenditure for those items as necessarily belong to the account. Now I happen accidentally to have been called upon long since to acquire a considerable acquaintance with publishing and printing matters, and I can tell you roughly at once what is the addition which has to be made to the wages of compositors, or for other charges in printing-houses where everything to be included is calculated and managed by persons of large experience on the principles of rigid economy. It is an addition of fifty per cent. For that statement I can give you the highest authority. That is to say, if you are paying, say, £22 per week for compositors' wages, you must add to that £11 a week to know what the composition has cost you. As you will see, this rule of trade works out quite accurately when we come to a detailed estimate properly drawn up. Thus, the real calculation for our JOURNAL stands in this way:

Composition and reading for JOURNAL (thirty-two pages) including advertisements (£29 a week) . . .	£1,508
Difference of rent, rates, and taxes (deduct £110 from £400) . . . . .	290
Repairs . . . . .	40
Water, gas, coals, and insurance . . . . .	40
Extra cost of housekeeper and cleaner . . . . .	40
Warehouseman . . . . .	75
Extra clerk . . . . .	100
Capital and interest on £1,500 outlay (taking for twenty-one years, 3½ per cent.) . . . . .	120
Plant and renewal . . . . .	120
	<hr/> 2,333

Now that £2,333 *per annum* is what it will really cost us to print our own JOURNAL, against £1,900 which we are paying now: thus showing no profit, but a loss of about £400. I will go further than this, for, being fully convinced from some knowledge which I have on all matters in connection with printing and publishing, that the professional printer really works at a very small margin of profit, and can from his collateral sources of occupation for his men, compose a weekly journal much more cheaply and efficiently than its proprietors can do it for themselves, I wrote last Friday to Mr. Richards, asking him whether, if he had a contract for five years for the composition of the JOURNAL, instead of his present hand-to-mouth tenure, he could make any reduction in his present contract price. I will read you his answer. [A letter was here read, in which Mr. Richards said that, with a five years' contract, he would be able to make a reduction of £175 a year on the journal of sixty-four pages; or, if the Association decided to do its own machining, to provide the composition of a JOURNAL of sixty-four pages for £2,080 *per annum*.] On the other hand, if we endorse the proposition of the Committee of Council to take the Strand premises and undertake our own composition, it will cost us, as I have shown, £400 more than we are now paying, and

£600 more on the reduced "five years' contract" which Mr. Richards is willing to undertake. I may say further, as a matter of fact, that the private proprietors of journals, such as the *Saturday Review*, *The World*, and other weekly journals of the kind, although certainly not less anxious than we should be to realise an economy in composition, have all, long since, satisfied themselves that it is to their advantage to have their journals composed and printed by large printers, such as Spottiswoode, Saville and Edwards, Robson, and the like, in whose hands has been placed the great majority of weekly journals similar to our own in London. I am aware of a large music publishing firm, who, after three years' trial, found that they lost £800 a year, by printing their own music. We may be quite sure that if private business proprietors do not find it to their commercial advantage to print their weekly papers, an amateur committee of medical men are not likely to make much profit by taking it into their hands. I have obtained on this subject the experience of one of the largest newspaper proprietors and most able publishers in London. [A letter was here read, confirming Dr. Grigg's opinion on the subject.] As a matter of fact I am satisfied that the General Secretary's calculation of profit upon our composition is so absolutely inadequate, and has omitted so entirely to take into consideration many ordinary commercial costs beyond and above those of mere wages, that it is absolutely and entirely untrustworthy, and I believe this meeting may rest assured that there is not only no profit in the scheme whatever, but an actual loss. If from considerations of economy we pass to those of efficiency, it is, of course, obvious that it is of very great convenience to have at disposal the whole composing staff of a great printing firm in case of emergency. My experienced colleague in the Metropolitan Counties Branch, Dr. Alexander Henry, has informed me that he especially directed the attention of the Committee of Council to this point in a letter, which I hope will be read at this meeting. He, after twenty-five years' experience of the JOURNAL, views with the greatest alarm the proposition to rely for producing the JOURNAL upon a restricted staff of compositors in our own employment. He tells me that it has been one of the great elements of efficiency in the JOURNAL, that when a great pressure of matter has come in on the last days, the services of a large staff of well-experienced printers could always be thrown in at once for extra composition; and that, for example, when the week before last an early copy of the Medical Bill was obtained late on Wednesday, it was printed at full length in the JOURNAL the next day, and in no other. This, Dr. Henry tells me, is liable to happen at any time; and the possibility of being able to meet the pressure is of great advantage to the JOURNAL. Dr. Henry is an excellent practical authority on the matter; he looks forward with the greatest apprehension to the proposed change, and I do not think that his opinion—that the proposed arrangements will not tend to the efficiency—is to be slighted. In fact, it has self-evident common sense in support of it. So much for economy and efficiency in printing. But then it has been said in a statement put forward by the Committee of Council, and will no doubt be again said to-day, that by taking a large office in a prominent position in the Strand, we shall improve our advertising connection. (*Hear, hear.*)

So far as I understand advertising, advertisers spend their money in proportion to the circulation of a journal, and not in admiration of its premises. So long as the JOURNAL was of small size and influence, and circulating only 1,800 to 2,000 copies, which was the case ten years ago, so long the advertisements brought in only £500 or £600 a-year. In proportion as the importance, popularity, and circulation of the JOURNAL increased, so did its income from advertisements increase; and without moving its premises at all, as its circulation rose, in five years, to four thousand or five thousand copies a-week, so did its advertisements concurrently rise to about the value of £2,000. In the subsequent five years, as its circulation has risen to between eight thousand and nine thousand copies a-week, so has its advertising income risen proportionately to about £4,000 a-year. If its circulation go on increasing, we may expect its income from advertisements to go on increasing. On the other hand, if the JOURNAL were to fall off in value and in circulation, and go back to its former standard of circulation of two thousand copies, you might take Buckingham Palace as an office, and that would not prevent its income from advertisements from falling off. [*Laughter.*] So far as advertisements go, they have risen as the circulation has increased, and that is the law of advertisements. There is no reason to suppose that we, as amateurs, can make a new law for ourselves. I went into these figures with the fullest desire to find that any economy was realisable; and until I had thoroughly examined the figures, I concluded that such was the case, although I saw, when the statement was made at the last Committee meeting, that the anticipated profit of £800 or £1,000 was greatly over-calculated. If it had been, I by no means, for other grounds, think

that the present costly premises in the Strand, intended to combine the sale and printing-rooms of the JOURNAL with the professional home of the Association, are at all desirable. Nevertheless, it would have been extremely satisfactory, with the view even to a separate arrangement, to have had the possibility of realising an alleged saving in the printing-office. But it is altogether an error; the estimates were crude estimates; the estimate of profit is a document which any business man would laugh to scorn, and it bears its own fallacies on the face of it to anybody who looks at it, and who knows anything whatever on the subject of printing on the one hand and the details of the Association business on the other. I cannot easily conceive how such a document could ever have been put before us, the Committee of Council, by any one professing to act as their business officer, or how we, the Committee of Council, could have been induced to accept so ridiculous a statement, and publicly to adopt it in a resolution as the result of "an exhaustive inquiry". However, I leave that responsibility to whosoever it may belong, and I conclude this part of my statement by reaffirming with the utmost confidence, and staking my reputation on the statement, that under no circumstances could the saving, which could be effected by taking the composition of the JOURNAL into our own hands, exceed a nominal sum of £200 a-year, without calculating the increased costs, which would result in a loss of from £400 to £600 a-year. It would undoubtedly greatly injure the efficiency of the printing arrangements, as Dr. Henry has pointed out, and as all practical proprietors of journals would recognise.

I pass now to the even more important question of whether it is professionally desirable to take costly premises, including a shop, in the most expensive business thoroughfare in London, and to select premises of such size in that situation as to include suitable meeting-rooms for the Committee of Council and for the Subcommittees of the Association, and waiting-rooms. I leave for the moment altogether Mr. Hutchinson's plan, warmly approved by the leading members of the Association, to whom it has been mentioned both in and out of the Metropolitan Counties Branch. He proposes to establish a writing and reception-room in the professional home of the Association, to which country members and foreign visitors can always come when they have to be in London for a day or two; to which they can have letters and telegrams addressed, and where they can obtain information as to the medical engagements of the week in London. That plan is only now in process of maturing; it was first brought before the Branch last summer, and has not yet been brought into complete shape. I may point out that if the Committee of Council had shown a desirable freedom of statement in the preliminary stages of this matter; if they had in their report to the Association in August last announced that they were contemplating taking a permanent central house or home for the Association, which should comprise its Committee and Council rooms; they would at once have necessarily been fully made aware of all the details of Mr. Hutchinson's scheme, and would probably also have received other suggestions from other quarters fully as worthy of consideration. I very much regret that this preliminary statement of their proposed novel scheme and large expenditure was not made. I think the Committee of Council probably now feel that they would have had everything to gain by taking counsel with the Association at large upon their plans, instead of proceeding to spend the money and carry out quietly their plan, and then to ask for the sanction and approval of the members of the Association at the annual meeting, when everything has been done. But leaving this aside as an extra suggestion, and dealing only with the recognised wants of the Association, I think it is plain upon the face of it, and every one will agree with me that, professionally, the proposed shop in the Strand cannot raise the status of the Association. Our Association has arrived now at a great position. It has now become a recognised factor in influencing Parliament, in the formation of public opinion, and in communicating with functionaries of all kinds, and people of high rank and station both in and out of our profession, on questions affecting all the relations of medical men to the state and to the country. When they are summoned to committees, or when they desire to confer with our committees or with our officers, they will, on this plan, find the British Medical Association treated as a mere appendage of the JOURNAL, and occupying apartments over a shop in the Strand. Supposing that our business interests require a separate printing and publishing establishment of our own, which I am sure they do not, and I hope I have convinced you that they do not, still that might be obtained in an unpretending situation, in the neighbourhood of the ordinary localities of printing and publishing shops, at a modest rental. A dozen such could be found suitable for the purpose, at an hour's notice, at a net rental of a third of what it is proposed to pay for and expend on the premises in the Strand. The balance might very properly be expended in selecting as a professional home of the Association suitable premises such as those of the Medical

Society of London, or a house situated in the centre of a professional neighbourhood, in a quiet street, suitable to the character and to the dignity of the Association. Such houses are to be had at moderate rentals, and both desiderata might be found separately at a less expense than is now proposed to incur for converting an upholsterer's shop in the Strand, which it is intended to make the future home of the British Medical Association, surrounded by shops and eating-houses. If that intention be carried out, we take our rank distinctly as an association of trading doctors. Everyone who comes upon professional business must visit the shop. He must enter by the shop, or alongside of it, through a long dark passage, and he will find somewhere upstairs the professional rooms of the Association. In fact, one of the items on which we are going to spend £1,000 is, I see, entered on the estimate, £100 for a shop-front. Now, a shop-front is all very well in its proper place, and I am the last man to attribute anything less than its proper importance to the value of the JOURNAL as the mainstay of the Association; its great propagandist agent, the great source of its prosperity and of its income. But this is no reason why we should insist on annexing ourselves to a shop. Let each thing have its due proportion. Let the central home of the Association be situated in a quiet neighbourhood, and arranged in a fashion suitable for its purposes of committee-rooms, council-room, and, I hope, reception and reading-rooms. Let me say that this is a subject on which I believe the Committee of Council will find that the members of the Association at large have a very strong feeling. And let me add also that we have an excellent example of dignity and success before us in another similar association, whose instincts might be supposed to be less fastidious in this respect, and who, nevertheless, have known how to combine commercial success with an almost professional dignity in their arrangements. I mean the Pharmaceutical Society. It also has its weekly journal, which is a commercial success. Let me add, by the great openness with which the council of that association report at the fullest possible length their proceedings and even their discussions in the *Pharmaceutical Journal*, they offer an excellent example to our Council; but, although a society of keen traders, they have recognised the facts that they can best consult economy by having their journal printed by contract with a professional printer, and their journal is actually printed a very few doors from the house of the present printer of the *BRITISH MEDICAL JOURNAL*. But the central home of the Pharmaceutical Society is a building of which any society may be proud. It is situated in Bloomsbury Square, as most of you know, with a museum and library attached, and, although they are not afraid of the shop, they do not think it necessary, in the semi-professional functions which they exercise, to annex the office of their society to their shop. I commend that example to this meeting. I have taken a great deal of trouble since I was led to consider this subject in investigating all its details. I have endeavoured, without sparing trouble, and as honestly as possible, to look at all sides of the question; and the conclusion to which I have arrived is that contained in the resolution which I now have the honour to submit to you, and which I will again read, in the hope that it will commend itself to your support. If it do not, I shall have no objection to the whole subject being referred to a committee for further information.

Dr. DAY (Stafford) seconded the resolution. He said that it was out of no feeling of disrespect to the Committee of Council that he took this course, for they were a body who had earned the general esteem of members. [*Cheers.*] His reasons for seconding the motion was that he thought the printing business should not be associated with the offices of the British Medical Association. The social, professional, and scientific character—the original characteristics of the Association—ought to be maintained; and it would be a misfortune, he thought, to have the commercial character imported into it, as it would be by undertaking to print the JOURNAL, and by the Association having a shop. The medical publishers, such as Churchill, did not print their own books, and what these had not thought it advisable to do the Association would not. He objected strongly to the proceedings of the Committee of Council in taking the premises.

Mr. HUSBAND: I now rise—the motion having been seconded—to state, on the part of the Committee of Council, the reasons which have led them to have—not a shop, but offices—offices which are compatible with the dignity and usefulness of the Association. I feel that I have a difficult task in having to answer a long speech read out as Dr. Grigg's has been—rapidly, and with many *ex parte* statements, letters, and such like, which no one else on this side of the table has had an opportunity of weighing. In the year 1871, the Committee of Council found that the Association was not financially prosperous—rather the reverse. Now why was this the case? The Association was not prosperous because its business was carried on in two different places—in Birmingham and in London. We had busi-

ness premises in London without superintendence, and the executive here in Birmingham, and a debt of nearly £2,000. [*Hear.*] We found that must change our plan. I hold in my hands a report made at that time—I will read it if you desire it—it was made, after full consideration, by our editor then and our editor now, Mr. Ernest Hart. [*Cheers.*] Mr. Hart is a practical man—[*cheers*]—a man who should know something about this business; and Mr. Hart made a carefully considered report to the Committee of Council advising us to undertake the printing of our JOURNAL. Remember what was then our position. We owed our present printer, Mr. Richards, a considerable sum, we were in debt otherwise, our members were considerably fewer, so that our income was very considerably less, and yet Mr. Hart, in his report, contended that if we took upon ourselves the work of printing our paper, purchasing the material with borrowed capital, it would be advantageous to the Association. [*Cheers.*] We then said, "No, we are not going to do this on borrowed capital; we are going to make a great change, by combining all the business at one centre, by having a managing secretary; and we will see how we get on with this business first before we attempt more". [*Cheers.*] We made the change, and two or three years ago we found we could not conduct the business we have to do in our present offices, and no one who passes through the gloomy cavern of our present offices can surely say that they are compatible with the "dignity of our profession", as well as with the standing of the Association. [*Cheers, and a voice, "Admitta!"*] Well, then, when we now turn out, as we are obliged to do, we must have new offices to go to; and when this was before us, we naturally took up the consideration of being our own printers; a question pressed upon us by our editor Mr. Hart when we were in difficulties; and we weighed the matter by the light of our position that we were enabled to pay for the outlay—that we have the capital for the plant. [*Cheers.*] We had and have no personal interest in the matter [*cheers*], and Mr. Fowke, our able and painstaking secretary, had and has no interest in the matter, beyond the desire to benefit the Association; and we, the Committee of Council and Mr. Fowke, are only taking upon ourselves additional work by our endeavours to advance the interests of the Association. [*Cheers.*] If we had consulted our interests—our repose—we should have let things go on; but we have always considered the interests of the Association as standing first, and the Committee of Council have often had to come to London upon the business; they have spent their money and they have spent their time, with the single object of the good of the Association. [*Cheers.*] Now, Dr. Grigg should have known that we have considered all the details he has given us. He has given us Dr. Henry's views; but against Dr. Henry I place Mr. Ernest Hart's report made to us, proposing to extricate ourselves from difficulty by undertaking our own printing. [*Cheers.*] In Dr. Grigg's view and Dr. Henry's view, we should have two separate establishments, but Mr. Hart advised—and the wisdom of the advice was apparent and obvious—that the whole business of the Association should be done at one establishment; that the presence of the head officer of the Association was to be a source of control; and Mr. Hart's estimate—which can be read if desired—included the rent of rooms for the secretary; and Mr. Hart added that a large part of the advantage of the then proposed new arrangement would be lost if the whole establishment should not be thus combined. Reference has constantly been made to a "shop". Now it is not a "shop" which the Association wants, but offices. We want headquarters where the Committee of the Association can meet, and properly meet; and where the whole business of the Association may be done under one roof. [*Hear.*] I have here an estimate of other places, which might be had cheaper, it was said, but I defy Dr. Grigg to take whoever he may to these places, and then come to our premises without its being declared that our choice is the best in every respect—in character, in value, and in accommodation. [*Cheers.*] The architect whom we have consulted, and who has given us his opinion as to other places, says that the position is better, and that there is no comparison as to value against the other places offered. [*Hear.*] We have investigated the particulars of the other places, and have visited them; but we say that these are not places where the work of the Association could be properly carried on. There has been talk about the "shop", and about the necessity of pursuing science, but you could not have scientific grants with an empty purse; and I should like members who talk about the "scientific purposes" of the Association to give a moment's consideration to the thought of where the money for grants comes from. Unless you have a considerable balance you cannot pursue the "scientific aspects" of the Association. Your expenditure on the JOURNAL is met by your income; but if you had not had a balance, how could you have done what has been done? If you had the accounts before you, as I have them before me, you would be able to see what the Association

has been able to do now by the aid of these despised advertisements in the JOURNAL, raised, too, not by canvassers, but by Mr. Fowke and his clerks. [Cheers.] Mr. Fowke had raised the advertisement receipts to double what they were, and that fact has enabled the Association to give scientific grants, to give an improved JOURNAL, for we have paid double the amount even lately paid to contributors—nearly entirely members of the profession—and to that fact is due our being clear from debt, and to our having a balance to-day. [Cheers.] Now is not this a high position to have achieved? [Cheers.] Dr. Day says, "Let us be a scientific body", but I say we cannot, as an Association, be a scientific body, pure and simple. [Hear.] Our JOURNAL—the most ably conducted of all the medical journals—[cheers]—finds its way to the hardworking general practitioner in a way which no other journal does; and for his fee of a guinea a-year he has his membership of the Association; he has his association with a brotherhood of his profession, and he has that ably conducted JOURNAL week by week. What enables us to place before the hardworking practitioner this JOURNAL, practically for nothing, is the fact that we conduct our business in a right way, and that we have a business. [Cheers.] Now, as to the scheme of some of the London men, with respect to making a "home", as they call it, for the Association, the London men have a club where they can go, so that they should not want a club in the Association. [Cheers.] Well, then, say that you have a room where the members from the country could go, I ask, of what good would that be to men in the country? [Cheers.] When we go to London we do not want to go to reading rooms and read medical works, but to enjoy ourselves or to transact business; and, when we are tired, to go to our lodgings or hotels. [Hear.] It is nice sometimes and cheering to meet medical friends, but, as a rule, you will find that when country people go to London they would prefer to leave the "shop" at home. [Laughter and cheers.] Dr. Grigg's statements have been fairly met, and from the information we have had as to the printing, we can say that Dr. Grigg's calculations are based upon the present number of pages, while, as our editor has been urging us to give him more space, we are desirous to raise the paper to sixty-four pages in place of forty-eight, and if our calculations are correct, and we are as likely to be correct as Dr. Grigg—[cheers]—we shall give you a better journal of sixty-four pages, and we shall put £500 a year in the pockets of the Association. [Cheers.] You must remember that we are obliged to go somewhere else; our offices cannot remain in Great Queen Street; and even if we went into a back street, as recommended to us, we should not save £100 a year upon our present proposal. We have secured a building sufficient for everything; we have carefully gone through the calculations made to us; we have them here, and I would read them to you, but that I am afraid of taking up your time; but there they are (holding papers before the meeting), and I pledge myself that they have been fully, even painfully, considered. Mr. Callender, of London, went through these figures, and he was so satisfied of their correctness that he moved the adoption of the report. [Cheers.] Now this has been done in no hasty manner. It was first of all before the Committee of Council, referred by them to the subcommittee, who carefully considered the matter, and then referred it to the Finance Committee, who also considered it, and referred it to the Committee of Council. Now it would be a most extraordinary thing, if this were a foolish or absurd scheme, that there was not one dissentient voice throughout all these references of all the persons who heard the whole *data*, or that all these several committees should have each passed the matter unanimously. Now the Committee of Council, with a scheme which had passed through these ordeals, felt that they were going to confer a great boon upon the Association, that they were going to give a better journal at a better rate, and to be independent of the printers, and all printers are under certain influences. [Hear.] Dr. Grigg gave us the names of one or two journals printed by printers for their proprietors; but look at the other side of the picture, at the papers which are printed by their proprietors, as the *Church Times*, the *Era*, the *Builder*, the *Lancet*, the *Watchman*, the *Athenaeum*, the *Guardian*, the *Horticultural Journal*, and a whole host of class papers, against his of the *Pharmaceutical Journal*. The number of papers printed at their own offices is enormous. Dr. Grigg has stated that, if we will give the present printer a contract to print for five years he will allow us £200 a year, so that the action of the Committee has resulted in an offer to lessen our payments by £1,000. [Cheers.] But still the printer would expect to make a profit, and would make a profit. [Hear.] We have considered all things, and we have data to go upon that we shall save beyond this promised reduction of £200 a year, and, besides, shall have the advantage of being in our own offices. Every one who has been to see these offices has been struck by their great capabilities, and by the possession of them you will have a building for twenty-one years which will be fully equal to the growing wants

of the Association. [Cheers.] If you do not go there, I do not know where you will go to obtain the like accommodation. I have gone with Mr. Fowke to various places, but I have not seen one building which was at once so suitable for the public business of the Association in relation to the JOURNAL and the executive business of the Association. [Cheers.] I trust you will support men who have painfully, honestly—[cheers]—and carefully weighed this matter. I have no interest but yours in the matter. [Cheers.] I will move as an amendment,

"That, in the opinion of this meeting, the arrangements contemplated by the Committee of Council in leasing the premises in the Strand are of a nature to promote the successful conduct of the business of the Association." [Cheers.]

Mr. BAKER seconded the amendment.

Dr. ROGERS said he was in a position to commend and support Dr. Grigg's motion. The Council proposed to save money by combining the two branches of the Association—the printing with the management part. Now, the question was, would this be the case, would money be saved? That certain economy had been effected in what the Council had done by having one place, he was ready to admit. [Hear, hear.] But that was not the point, nor was that the case as now put, for it was said that £800 a-year would be saved on an expenditure of £1,900—a ludicrous statement. The Committee of Council proposed to set up as printers; and Dr. Grigg appealed to practical printers to give him advice; and he showed that, instead of a saving of £900 a-year, there would be a loss of £300. The Committee of Council looked to an increase of advertisements by taking a shop. ["Office."] They might call it what they pleased; but, when they proposed to spend £100 to put in a plate-glass front, he called it a "shop". Now, the advertising power of the JOURNAL was in its circulation, and not in the position of its offices. The fact was, that the Committee of Council were going into business. [One of the Committee of Council: "We have been in business for a long time."] Mr. Cobden once mentioned to him that he had great respect for the medical profession, as the members of it understood something of their calling; "but", Mr. Cobden added, "I hardly know one who knows anything else". ["Question."] That was a fair observation directed against the Committee of Council being the men to go into business. Dr. Rogers concluded by urging the members to look before they leaped.

Dr. B. FOSTER said that no doubt Dr. Rogers's acquaintance with the late Mr. Cobden was one of the great privileges of his life, and that he could calmly suffer with others in the depreciation in which the late statesman held the business habits of the medical profession. [A laugh.] But what was Mr. Cobden's testimony and opinion, by the side of the fact that in a few years the present Committee of Council had been able to raise the Association to its present position of a powerful organisation—a position of dignity—and to save several thousand pounds—this, too, without acting in a commercial spirit, but after giving several thousand pounds to scientific purposes; and it was a proof of the business qualities of the Committee of Council that they had effected savings on all the changes they had made, so that the reflection upon the business qualities of the profession, based upon the words of the late Mr. Cobden, fell to the ground. [Cheers.] The Association had been advised to look before it made its leap; but he could assure the Association that the Committee of Council had taken a long and deliberate look before they leaped, and had well measured the distance, so that they felt they should safely land on the other side. [Cheers.] The statements—not controverted—as to the savings which the Committee of Council had been enabled to make in the working of the Association, had been the result of deliberate consideration and thought, and the experience gained it was intended to apply to the Association in future. [Cheers.] Let the members weigh the facts of the savings effected by the Committee of Council as so much testimony in favour of the views they now held in regard to their new action. [Hear.] In undertaking this greater responsibility, they were doing extraordinary service for the Association; and he desired the Association to bear in mind this fact: that the JOURNAL required to be more brought before the public; for its advertisement income at the present time bore no proportion to what it ought to be, considering its great, certain, and increasing circulation as the organ of a great and increasing Association. [Cheers.] Other journals of smaller circulation and less influence had larger advertising incomes; and the Committee of Council were taking the best steps to place the JOURNAL on a proper footing in this respect. [Cheers.] The Committee of Council were taking steps to do this; and, when it was done, they would give their best thoughts and attention to provide a "home" in London asked for by the London men, and he had no doubt that the medical club would give Dr. Grigg and every friend of Dr. Grigg a hearty welcome. [Laughter and cheers.]

Dr. HENRY said that there could be no doubt that every one in the room desired the prosperity of the Association; and each side could give the other full credit for that feeling. He must protest against the insinuation conveyed in certain expressions used by Dr. Foster and other speakers, that the metropolitan members desired special advantages for themselves. In all that they had proposed with reference to the subject under discussion, the members in London had consulted for the benefit and convenience of the country members of the Association. He quite agreed with those who desired that the Association should have a house worthy of the high position to which it had attained; but he hesitated to go with the Committee of Council in their proposal to undertake the printing of the JOURNAL. He had already expressed his views on the subject in a letter to the President of Council; pointing out especially, among other matters, certain difficulties that would probably arise in regard to having a sufficient staff of compositors and keeping them fully employed. The views which he held were in substance the same as those put forth by Dr. Grigg.

Dr. GRIGG having briefly replied,

The PRESIDENT put the amendment to the vote; and a large majority voted in favour of it, seven or eight only being against it.

It was then put as a substantive resolution, and carried, with five against.

#### THE PRIVILEGES OF LADY MEMBERS.

The PRESIDENT stated that this subject would be deferred until the annual meeting, as the gentleman who had intended to move a resolution on the subject was unable to be present.

Mr. OLIVER PEMBERTON moved:

"That a Subcommittee be appointed to inquire as to the privilege of lady members, with power to take counsel's opinion, and to report to the annual meeting."

Mr. LISTER thought it would conduce very much to the interests of the Association if some steps were taken in the interval between this time and the annual meeting with regard to this subject; and he seconded the motion.

Mr. GANGEE moved as an amendment:

"That the Committee of Council be instructed to take the opinion of counsel as to the rights of the lady members, and to report to the annual meeting."

Mr. SOLOMON seconded the amendment.

Dr. WADE, Dr. EASTWOOD, Dr. BORCHARDT, Mr. LAWSON TAIT, and others spoke; and ultimately a division was taken, when there appeared: For the amendment, 40; against, 38.

It was moved by Mr. SAMPSON GANGEE, seconded by Mr. HUSBAND, and resolved unanimously:

"That the best thanks of this meeting be given to Dr. Eason Wilkinson for his conduct in the chair."

The meeting then separated.

#### THE EXISTING STATE OF OUR NAVAL, INDIAN, AND ARMY MEDICAL SERVICES.

ON Monday, the 1st instant, the thirty-sixth session of the Army Medical School was opened at Netley with nineteen candidates for the British army, twenty-six for Her Majesty's Indian service, and eleven for the Royal Navy. There was a large attendance of officers and gentlemen from the neighbourhood, including Major-General Bayley, C.B., R.E.; Inspector-General Domville, C.B., R.N., Principal Medical Officer of Haslar Hospital; Colonels Stewart and Farnar, Major Bullen, R.E., and others. The Introductory Address was delivered by Surgeon-General Longmore, C.B., Professor of Military Surgery. The lecturer gave a hearty welcome to the new-comers, and assured them all the authorities at Netley were anxious that the time of their stay should be agreeably as well as profitably spent, and, with much feeling and eloquence, exhorted them to turn to the best account the means of improvement placed at their disposal. He made some highly important remarks on each of the three branches of the public service, especially with regard to the Army Medical Department, in respect to its condition for entering upon a campaign if required to do so. These remarks have been forwarded to us; and as the subject is one which has excited a good deal of attention of late, and is still doing so, we at once lay the substance of them before our readers.

The several branches of the public service in which you are destined

to apply your professional knowledge offer, each of them, a noble field for your exertions. Each branch has its special features, its special advantages; and, as there is no sphere in life in which unmixed good is to be found, I may in fairness probably add, each has its special drawbacks. In all, however, to those who are disposed and competent to turn the opportunities they offer to good account, the advantages very far outweigh the drawbacks.

In the Royal Navy, the rank and position of the medical officers, the rates of pay, and the retiring pensions have been greatly improved of late years, while personal economy can be practised in it with less self-denial than in other branches of the public service. If serving on shipboard, you may be sure, if your professional attainments are such as to command respect, and you have a disposition open to be pleased, that you will meet with no want of pleasant companions; nor, in whatever part of the world you may be stationed, can you ever be without abundant means of enlarging your views and extending your knowledge in those natural sciences which have formed part of your education, and which are so full of interest to all of us. To some persons a sea-life is distasteful, especially to those who have not become used to it in early life; and this, no doubt, is one fruitful cause, joined with the demand for medical practitioners in other directions, why more candidates do not come forward for this branch of the service; but it is not to be forgotten, in these days of steam, that ships do not remain at sea for long periods as in former years, and that medical officers of the Navy, in the course of their service, spend much of their time in hospital establishments on shore.

The Indian Medical Service offers a magnificent field for the surgeon who is fond of his profession and ambitious of gaining distinction in it, whether in its technical, tutorial, or administrative aspects. I speak not only of the higher positions that become open to you in time—such as appointments in the great medical colleges of Calcutta, Madras, Bombay, Lahore, and Hyderabad, though not a few of the professorships in these are now held by medical officers who, comparatively a few years ago, sat on the very benches you now occupy, as well as other important charges in the Presidency cities and larger stations—but I refer to the positions in which relatively juniors are placed. Even in what may be regarded as out-of-the-way and minor stations, large professional practice and distinction may be gained in India. But certain qualities must be displayed in order to secure these results. The apathetic or the unskilful surgeon will not obtain them. There must be the desire for the practice in the first instance; cases must be almost sought for at first; in the next place, confidence must be gained by the exercise of ability and skill; and then opportunities of practice will follow of their own accord. About three weeks ago, I received a printed report of the work done in 1877 at a small dispensary at Azamgarh by Mr. R. C. Sanders, who passed through this school with much credit about seven years ago. Between the 1st of January and the 26th of December last year, Mr. Sanders performed 831 surgical operations. They were followed by only 5 deaths, but 13 of the cases were still under treatment at the time the report was closed. Among them were no fewer than 523 operations for extraction of cataract, and 197 cases of indectomy. Imagine upwards of 500 cases of cataract extraction in one year; what would the most eminent practitioner in ophthalmic surgery in our great metropolis say to such a number coming under his care in that time? And conceive the gratification to all concerned in the results: 336 with sight successfully restored, and 95 relieved, out of the number! Each successful case increased tenfold the advent of blind people from the surrounding villages. After referring to the number of applications in the month of July, the report states: "At the beginning of the year, the difficulty was to get the patients to submit to operation: now the difficulty is to keep them off the operating-table." In a letter dated February 28th of this year, written from Moradabad, in Rohilkund, Mr. Sanders asks that the amount of his practice at Azamgarh in 1877 may be mentioned to you at the beginning of the session, and I have accordingly done so; and he adds: "The field for work in this country is boundless. I have but just been transferred to this station, and have, in the first month had over 180 cases to treat, mostly cases of cataract." Any one may well be proud to belong to a service in which such opportunities of professional usefulness are to be obtained.

The medical department of the British army is also a service in which not only great opportunities of usefulness, but also many sources of gratification, are open to all who join its ranks. You may justly feel a patriotic pride in belonging to it. Its efficiency has been so persistently decryd for some time past in a certain portion of the press, so much obloquy has been cast upon the officers at the head of it, that a feeling of uncertainty and distrust in regard to it has been propagated far and wide among those who have no personal acquaintance with it. It seems not improbable that these constant attacks have, in some degree,

effected the harm which they appear to have been designed to accomplish; and that they have kept many young surgeons of promising ability from seeking commissions in it. You who have had the courage to come forward, in spite of these deterring influences, are not likely to regret the step you have taken. You will find honourable employment, with remuneration above the average of what is obtained in early years in civil practice, and at the same time free from most of the difficulties and anxieties inseparable from it. You will be associated with an army which, though inferior in numbers to many others, has no superior in patriotism and fame; and that has the merit of never being employed as an instrument of aggression and injustice. A distinguished general officer, Sir Garnet Wolseley, has recently published a comparison between the state of the British army, in strength and organisation at the present time, and its state at the time of the Crimean war. He has shown the improvements which have been made in it, and how much more competent it is now to take the field, and to maintain a struggle, if called upon to do so, than it was then. It would be easy, if time allowed, to show that, what is true of the army as a whole, is equally true of the medical part of it. I will only mention a few of the most striking facts in this respect. At the time of the Crimean war, we had not even the vestige of an hospital corps. The ordinary plan for meeting the want of hospital orderlies was by abstracting effective soldiers from the ranks of regiments; and when, during the war, attempts were made to form an independent hospital corps—composed as it was at first of worn-out pensioners, and afterwards of untrained civilians—the efforts only ended in failure. Now we have a regularly trained and disciplined Army Hospital Corps, of considerable numerical strength. We had no organised system for the removal of the wounded; no trained stretcher-bearers, nor establishment for training them; no equipment nor organisation for forming dressing-stations in advance of the field-hospitals; and no fixed arrangements for the field-hospitals themselves. The band-men were supposed to be available for carrying the wounded away, but it was a mere supposition; they were neither taught the duty, nor were there any existing orders or means for making them do it; and, practically, when the wounded were removed, they were carried off the field by their comrades—a most objectionable proceeding. Now, we have systematically organised and trained "Bearer Companies", complete in their essentials of *matériel* and *personnel* for all the duties between the fighting lines and the field-hospitals, including those of transport as well as those of the dressing-stations. The field-hospital establishments are complete, and adapted to the exigencies of modern warfare. At the time of the Crimean war, the troops marched and fought the battle of the Alma without a single ambulance-wagon with the army; the only one that was landed was left, where I saw it, on the shore at the place of debarkation; and when, at a subsequent period, some ambulance-wagons were brought to the army before Sebastopol, they were so cumbersome, there were such difficulties in moving them, that they were abandoned as useless. Now, not only are there large stores of ambulance-wagons and other conveyances for sick and wounded soldiers available, but there is every reason for believing that there are none so perfect for their particular purposes, certainly none more so, in any army in Europe. Some British ambulance-wagons were sent to France during the war of 1870-71; one detachment of them was employed with the French, another with German troops. One of the English medical officers with the latter afterwards published the fact that, when the German surgeons wished special cases of wounds to be removed, they requested the use of the British ambulance-wagons in preference to their own—a sufficient proof of their ease of carriage: and when, after going through the trying work of the hard winter in France, they were brought back to Woolwich, all the essential parts of the vehicles were found to be as perfect as when they left it—a sufficient proof of the excellence of their construction; and there have been many improvements made in them, as well as in the other classes of ambulance conveyances, since that time. In short, in all respects—in organisation, in quality of equipment, and now, I believe, in the amount of it—if a British army be called upon to enter on active service, there is every reason for believing the medical department will be found far better adapted to meet the demands which will be made upon it, great as they now are in warfare, than it has ever been at any previous time. The majority of the medical officers, too, will be found better prepared than they had the opportunity of becoming formerly. The instruction at this school, supplemented by the Bearer-column drill at the dépôt at Aldershot, must produce this result. Sir Garnet Wolseley, in his paper before alluded to, has recalled to recollection the reply of the War Minister to a Member of the House of Commons, who brought the want of ambulance conveyances in the Crimea, during the early part of the first winter, to the notice of Parliament. The Minister asserted that the reports on the subject were devoid of truth, because he knew for a fact that there were fully a hundred hospital panniers with the army. These

are articles which have not the remotest relation to ambulance conveyances. But it can scarcely excite wonder that the Minister did not know what field-hospital panniers were, since many of the army surgeons had no idea of their nature when they first started on the expedition. How could they? They had never had occasion for their use, and the panniers had never been shown to them. Such ignorance cannot occur again. I do not mean to say there are no matters connected with the department which one could wish to be different from what they are; but there is good reason for believing that whatever defects exist of importance will be rectified before long, and, at any rate, this is not the place to discuss them. It is with regard to the efficiency of the department, which has been so much decried in certain quarters of late, that I have been led to speak; and I hope I have been able to show there is not the slightest ground for the injurious attempts which have been made to disparage it in this direction.

In conclusion, let me recommend you who have just come to Netley to make yourselves acquainted with the character of our lost colleague Dr. Parkes, whose portrait has just been placed in the map-room, and with whose fame you must be more or less familiar. As a likeness, the picture is so admirably true that, looking at it, you will see what manner of man he was while in life; but, to know how he lived and how he worked, you must look elsewhere. You will not fail to see important evidence of his great industry, his earnestness in the search after scientific truth, and of his perfect freedom from prejudice in the valuable work on practical hygiene, which will be constantly in your hands as a text-book while you are here. You will be able to learn further from any of the memoirs which have been published of him, how unselfish he was in his aims, how resolutely and indefatigably he worked for the good of humanity at large, but especially for the welfare of the officers and soldiers of the army; and what great improvements he effected, without taking credit to himself for them, and certainly with remarkably few signs of gratitude or appreciation from those who received most advantage from them. The medical officers of the United Services, however, have not been forgetful of the benefits he conferred on them by his teaching and published works, nor the position he achieved—to use one designation given to him—of "the leading hygienist in the most hygienic nation in the world"; but, in concert with a few personal friends, they have testified to their appreciation of them by subscribing enough to found the "Parkes Memorial Prize", a gold medal, and £100, to be given triennially for the best essay on Hygiene: further, to obtain the memorial portrait just placed in the officers' mess-room: still further, I am happy to add, to establish a Parkes Medal, for the candidate who sessionally exhibits the highest attainments in the hygienic work which he so long directed at this school.

Only try to imitate him in his beneficent aims, and in his honest and loyal efforts to fulfil all his duties to the best of his ability, and you may be sure that you will not only satisfy those with whom you have to deal in the business of life, but you will enjoy what is still more important, that self-satisfaction, which will be a source of happiness to you under every condition in which you may happen to be placed, as long as life itself lasts.

#### THE HARVEY TERCENTENARY MEMORIAL FUND.

WITH great satisfaction we recognise the extent to which the Harvey Memorial project has been noticed by the general press. All the London daily journals referred to the occurrence of the three hundredth anniversary of the birth of Harvey on Monday last; they spoke of his beneficent labours in terms of grateful admiration, and called attention to the memorial-statue about to be erected at Folkestone. There also appears in most of the papers of to-day (Thursday) an appeal to the general public for £500 or £600 more, signed by the members of the London Executive Committee of the fund. The actual centenary was commemorated at Folkestone, at which the Rev. R. C. Jenkins, Honorary Canon of Canterbury, gave a lecture on "Harvey, and his Position as a Discoverer". There was a large audience, from which subscriptions to the Memorial Fund to the extent of about thirty guineas was obtained. Other subscriptions promised to or received by the London Honorary Secretary during the last fortnight amount to £130.

At the meeting of the Fellows of the Royal College of Physicians, held on Tuesday last, the subject was introduced, and notice was given by the Senior Censor of a motion to be brought forward at the next meeting of the Fellows, that the College, recognising how much it is indebted to Harvey, should subscribe one hundred guineas to the Memorial Fund. The Council of the Obstetrical Society, at their meeting on Wednesday, also passed a resolution recommending the

next meeting of the Council to make a donation of 25 guineas. The subscriptions, exclusive of these sums, now amount to £1,100. We are requested to ask the members of the profession who have not hitherto contributed to this most interesting object to kindly send their donations at once to either of the hon. treasurers (Sir George Burrows, Bart., or Mr. Prescott Hewett), or to either of the Hon. Secretaries (Mr. George Eastes, M.B., 69, Connaught Street, Hyde Park Square, London, W.; or Mr. W. G. S. Harrison, B.A., Town Clerk, Folkestone), or to pay them into the account of the Harvey Tercentenary Memorial Fund, at the Western Branch of the Bank of England, Burlington Gardens, London, W. Subscriptions from five shillings upwards will be very acceptable. Success is insured, if that feeling which should exist in regard to this subject should lead to practical action generally on the part of the members of our profession.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary meeting of the College was held on April 2nd. Permission was given to Dr. Willis to publish in his life of Harvey a letter in the possession of the College written by Dr. Harvey to Dr. Baldwin Harney.

A communication was read from the Secretaries of the "Harvey Tercentenary Memorial Fund" soliciting the co-operation and assistance of the College in providing funds for a proposed statue to Harvey.

Dr. Quain gave notice of his intention to move at the next meeting a grant from the College fund for this purpose. Dr. Quain also gave notice that he would propose that a banquet should be given by the College.

The Bill introduced by the Lord President to amend the Medical Act was then considered, and the following resolution was adopted:

"That a deputation, consisting of the President of the College and the Fellows to be nominated by him, be authorised to wait on the Lord President of the Council to point out the objectionable features contained in the Bill which his Grace has introduced into the House of Lords, to seek modifications of the same, and to report to the College."

#### THE MEDICAL ACT AMENDMENT BILL.

THE Medical Reform Committee met on Tuesday, at the Queen's Hotel, Birmingham, when the following members were present: Dr. Edward Waters, Chairman and Convener; Dr. Wilkinson, President of the Association; Dr. Falconer, President of the Council; Dr. Chadwick, Vice-President; Dr. De Bartolomé, Vice-President; Dr. Wade, Birmingham; Dr. Balthazar Foster, Birmingham.

The action of the Committee, and its communications with the Government and with Members of Parliament, were considered, and the Bill of the Government to amend the Medical Act, 1858, was condemned—

1. For not providing for direct representation of the profession in the General Medical Council;

2. For not containing compulsory enactments, to enforce the formation of a conjoint board of examination in each division of the kingdom, on the principle of equal fees and equal examination.

It was resolved: That the Chairman should, by a communication to every member of the Association, and, as far as practicable, of the profession, endeavour to obtain an expression of his adhesion to the principles which the Association has so long struggled to realise.

#### FORM OF PETITION.

The following form of petition was suggested. It must be *written* and not printed.

Unto the Right Honourable the Lords Spiritual and Temporal of the United Kingdom of Great Britain and Ireland, in Parliament assembled.

The humble petition of the undersigned, registered medical practitioners, residing in \_\_\_\_\_ and its neighbourhood, sheweth—

That a Bill, intituled an Act to Amend the Medical Act, 1858, has been brought into your Honourable House.

That, in that Bill, no provision is made for the introduction of direct representatives of the profession in the General Medical Council.

That the General Medical Council, as now constituted, consists of seventeen representatives of the Universities and Corporations, and of six members nominated by the Crown, together with a President, chosen by the other members of the Council.

That the representatives of the Universities and Corporations have exclusive interests to watch over, and exercise an overwhelming influence in the Council.

That the general expenses of the Medical Council are defrayed out of fees exacted from the members of the profession, and that the Universities and Corporations do not contribute to the payment of those who represent them in it.

That the medical profession, as a body distinct from the Universities and Corporations, is wholly unrepresented in the General Medical Council.

That the Bill does not provide compulsory enactments for the establishment of a conjoint board, for the examination of medical candidates in each division of the kingdom, on the principle of equal fees and equal examinations; and that such enactments are indispensable, in the interests of the public, to abolish the competition downwards in the granting of medical licenses and diplomas.

Your petitioners pray your Honourable House not to pass that, or any other Bill, unless provision be therein made for direct representation of the profession in the General Medical Council, and for the compulsory establishment of conjoint boards of examination, on the principle of equal fees and equal examinations in each division of the kingdom.

And your petitioners will ever pray, etc.

## ASSOCIATION INTELLIGENCE.

### COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, London, on Wednesday, the 17th day of April next, at Two o'clock in the afternoon.

FRANCIS FOWKE,

*General Secretary.*

36, Great Queen Street, London, W.C., March 25th, 1878.

### WEST SOMERSET BRANCH.

THE spring meeting of this Branch will be held at the Railway Hotel, Taunton, on Thursday, April 11th, at 5 P.M.

The following question has been settled by the Council as the one on which members should be invited to express their opinion at the said meeting after dinner:—"Is the Use of Water desirable in Dressing Wounds?"

The Secretary requests that early notice be sent to him of the title of any communication intended to be brought forward at the meeting.

W. M. KELLY, M.D., *Honorary Secretary.*

Taunton, March 16th, 1878.

### NORTH OF ENGLAND BRANCH.

THE spring meeting of this Branch will be held in the Board Room of the Guardians, at Hexham, on Thursday, April 25th, at 2 o'clock P.M.

The following papers, etc., have been promised.

1. Drs. Stainthorpe and Farmer: Case of Aortic Aneurism in a boy aged 13.

2. Drs. Stainthorpe and Farmer: Case of Contracted Knee-Joint, recently operated on by division of the Tendons and Forcible Extension.

3. Dr. Byrom Bramwell: On the Differential Diagnosis of Aortic Aneurisms and other Intrathoracic Tumours, with cases and specimens.

4. Dr. E. C. Anderson: On Leucine and Tyrosine, and their Diagnostic Value in Disease, with cases.

5. Dr. James Murphy: Exhibition of Tarnier's Obstetric Forceps.

6. Dr. James Murphy: On Puerperal Convulsions.

7. Dr. Philipson: Notes of a Case of Hematuria.

Dinner at the White Hart Hotel at 4.30 P.M.; charge six shillings, exclusive of wine.

G. H. PHILIPSON, M.D., *Honorary Secretary.*

Newcastle-upon-Tyne, April 2nd, 1878.

### BATH AND BRISTOL BRANCH.

THE fifth ordinary meeting of the Session will be held at the York House, Bath, on Thursday, April 25th, at 7.15 P.M.; HENRY MARSHALL, M.D., President.

R. S. FOWLER, } *Honorary Secretaries.*  
E. C. BOARD, }

Bath, April 1st, 1878.

## CORRESPONDENCE.

## HOSPITAL FINANCE.

SIR,—You gave insertion to some valuable suggestions, in your impression of the 2nd instant, by publishing the views of Mr. Henry C. Burdett on hospital finance. He tells us "the want of method in the system of management" causes the working of our large metropolitan hospitals on unsound principles; and he gives you a sketch in his letter as an illustration of the financial operation which concludes by the sale of stock. Further, Mr. Burdett tells us that in a particular instance a successful issue has been arrived at to prevent the evil of selling stock. Now, surely, if this step in the right direction can be reached by one institution, the managers of other institutions ought to be very desirous to learn how they can in like manner help themselves. Why not, therefore, try to mature the valuable suggestions which have now been offered? An annual conference of hospital managers ought not to be at all a difficult meeting to convene. There are board-rooms at all hospitals worthy of the name, and a circular from the chairman of any one ought to ensure a full representation of the remainder.

The letter to which I am now seeking to draw further attention from your readers seems to me one that ought to have been noticed ere now by some one of many years' more hospital experience than myself; but, failing a reply at the present moment from more able hands, I venture to try to keep this so excellent idea alive before those who are evidently most interested, and also before the public who subscribe to the several charities, and who have a right to ask that every available means to save unnecessary sales of stock should at least have a full and exhaustive trial.—I am, sir, your obedient servant,

HENRY N. CUSTANCE,

Secretary Metropolitan Hospital Sunday Fund.

Mansion House, E.C., March 20th, 1878.

## PHYSIOLOGICAL TEACHING IN DUBLIN.

SIR,—Misfortunes are said never to come singly; and, in the present instance, it would seem as if the fates had conspired to strangle any attempt at physiological teaching in Dublin. The decision of the Board of Trinity College as to registering places for physiological experiments, to which you have drawn attention in your leading article of to-day, is one which every well-wisher of the University, as well as every believer in physiology, must deplore. It is not, however, to this that I wish now to call attention, but to the state of affairs that exists, and is being most studiously protected, in connection with the curriculum of the Royal College of Surgeons in Ireland. The vast majority of our Dublin students seek the licence of the Irish College of Surgeons, and consequently the curriculum of this body forms the basis of the teaching in all the Dublin schools (the University excepted). This curriculum includes, amongst other things, attendance on three winter courses of systematic lectures on Practical Anatomy, Anatomy and Physiology, and Surgery, respectively. Two courses are required in Chemistry, one of which must be a winter (theoretical course); the other may be theoretical or practical. In none of the three subjects above mentioned is there more than one course of lectures, and consequently first, second, and third year's students are all taught together.

Now, sir, I doubt the advisability, to say nothing stronger, of requiring a student to attend three courses of lectures on any subject, more particularly when it is the rule, as it is here, for a student to complete his whole course and get his diploma in the space of two years and nine months. In surgery, possibly a complete course of lectures might be made to extend over three winter sessions, and still each part made reasonably intelligible to a junior student. Whether this be or be not done in the case of surgery, it certainly is not and cannot be done in the case of physiology. Physiology must necessarily be taught synthetically; a large number of subjects must be treated every year; and hence it comes that, when a student is asked to attend three courses, he is practically asked to do little; if anything, more than to attend the same course three times over.

Since my appointment as Lecturer on Physiology at the Carmichael School in 1872, I have each year given a duly advertised course of practical physiology on the type of the requirements of the English College of Surgeons. The course is, for the most part, one of history and biological methods, and consists of thirty meetings of the class of two hours each. As, however, students going in for the diploma of the College of Surgeons have to pay for three courses of physiology, but few of them are willing to pay for another. Hence I have never had many from this source.

At the request of some students, I made application, on March 28th of last year, to the Council of the College of Surgeons that attendance on the practical course should be allowed to be substituted for attendance on one of the three winter courses. This was refused, as being contrary to the by-law. But, as I was aware that the similar by-law in the case of surgery had occasionally (if not frequently) been relaxed, so as to allow the substitution of a course of operative surgery for one of the three winter courses, I again wrote on April 19th, requesting, as an act of special grace, that three students (named) should be allowed to substitute my practical course, then about to begin, for a winter one. The reply stated that the matter was under consideration. As I received no definite answer for nearly a year, I wrote on the 4th of the present month (March), requesting a decision one way or the other, as one of the three gentlemen was about to present himself for examination. The reply stated that the Council had referred the matter to the Committee of Inspection; the Committee reported, I am told, in favour of the certificate being accepted; but, on Thursday last, the Council decided not to accept it.

These are the facts of the case, and I think they show a distinct determination not to allow the introduction of practical teaching into Dublin. I am not one to uphold the breaking of a by-law. If a by-law be bad, let it be removed; if too stringent, let it be modified. But, if by-laws are broken at all, it ought to be on some definite principle. The only difference between the case of operative surgery and practical physiology is, that the latter course is far more laborious and occupies a much longer period than the former. Yet the by-law is broken in one case and not in the other. Then, again, the by-law requiring five lectures per week in anatomy and physiology is not complied with by the school of the College of Surgeons itself, and consequently, by the strict letter of the law, the certificates ought not to be accepted.

The truth is, medical teaching in Dublin is in a very unhealthy condition; and strong influence is being used to protect "vested interests". It is quite as easy to lecture to one hundred and fifty students as one hundred; while, if one year's batch of the one hundred and fifty were allowed to take a practical course, there would be considerably more than double the work and little, if any, more pay. But surely it is the lowest aspect of trades-unionism to prevent a teacher from giving two courses instead of one, more particularly when what he offers is now universally admitted to be essential to all adequate physiological teaching. As a matter of fact, a large number of our students who signified their intention of taking out my practical class this summer, if the certificate were allowed, are now, by the resolution of the Council, deterred from so doing. I have consequently decided, with the permission of the directors of the school, not to give the course.—I am, sir, faithfully yours,

REUBEN J. HARVEY.

7, Upper Merrion Street, Dublin, March 30th, 1878.

## MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS—Wednesday, April 3rd, 1878.

*Vaccination Law Penalties Bill.*—MR. PEASE having formally moved the second reading of the Vaccination Law Penalties Bill, MR. SCLATER-BOTH explained his objections to the measure, which he said would enable those who were opposed to vaccination to free themselves from the obligation already imposed by Parliament. There had been no increased tendency to carry on cumulative prosecutions during the last twelve months, and the action of certain of the guardians had been modified by the circular note of the Local Government Board.—MR. PEASE said the Select Committee which had inquired into the subject had reported strongly against the imposition of second penalties, which did not exist in Ireland, and had never been enforced, even if they existed, in Scotland. The Bill would carry out the recommendations of the Committee, and there was less reason to oppose it if, as Mr. Sclater-Booth said, the prosecutions were fewer than they had been.—EARL PERCY suggested that, inasmuch as in the last outbreak of small-pox the mortality was greater than it had been since, and in view of the popular prejudice against vaccination, it was desirable to have a full inquiry into the efficacy of vaccination.—DR. LUSH objected to the way in which the law was administered, though he was convinced that vaccination was one of the greatest boons ever conferred on mankind.—MR. W. E. FORSTER supported the Bill, with a view to the question being referred to a select committee.—MR. FORSYTH, SIR J. M'KENNA, MR. MITCHELL HENRY, and MR. EVANS opposed the Bill, which was supported by SIR T. CHAMBERS, while MR. SERJEANT SPINKS expressed himself in favour of an inquiry.—MR. GLADSTONE supported the suggestion of Mr. Forster, that the Bill should be read a second

time and an inquiry held into the administration of the law, as such an investigation would be of great value, not only in satisfying the public mind as to the efficacy of vaccination, but as to the manner in which it was performed; while suggestions as to its improvement could be considered.—Lord R. CHURCHILL then moved the rejection of the Bill, and this afforded several hon. gentlemen who had already addressed the House an opportunity to speak again. In course of the discussion, Dr. PLAYFAIR characterised the Bill as seeking to legalise the sale of an 'indulgence for a breach of the law, the principle being just the same as if a person were allowed to convey some one suffering from an infectious disease in a cab a second but not a first time.—Mr. SCLATER-BOTH said he could not support the Bill, neither could he feel justified in throwing any obstacles in the way of the second reading, and therefore he left the question to the House.—Mr. W. E. FORSTER said the Government could not leave the question as it stood, but would be bound, sooner or later, to refer it to a committee. On a division, the Bill was rejected by 271 to 82 votes.

## OBITUARY.

JOHN ROBERTS, M.D., M.R.C.P.L.

It is our painful duty to record the sudden death, at the age of sixty-eight, of John Roberts, M.D., M.R.C.P.L., on the 23rd ult., at Nice. Dr. Roberts practised for some years in Paris with success. In 1849 he settled in London, and soon became a popular physician at the West End, with a large and influential *clientèle*. Six or seven years since, illness obliged him to resign the active duties of his profession, and he retired into private life at Upper Norwood, usually wintering at Nice, where he died. By his patients he was beloved for his skill and kindness, by his colleagues he was trusted and esteemed for his high moral and professional qualities.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Board of Examiners, on April 1st; and, when eligible, will be admitted to the pass-examination.

Messrs. T. Kay Whitehead, William Stanwell, and R. Hanson Wolstenholme, students of the Manchester School of Medicine; Robert Jones, George F. Barnes, and G. Treverno Hockin, of St. Bartholomew's Hospital; W. Eckett Fielden, G. Ryding Marsh, and W. Washington David, of Guy's Hospital; F. William Marland and G. Mills Wasse, of St. Thomas's Hospital; George Welch and Arthur Northcott, of University College; W. Aloysius Day and T. A. Perry Marsh, of the Bristol Medical School; John Palmer, of the Middlesex Hospital; George Anand, of the Melbourne Hospital; David Lawson, of the Aberdeen School; Frederick J. Laimbers, of the Liverpool School; and Ewing McG. Aitken, of the Glasgow School.

The following gentlemen passed on April 2nd.

Messrs. Sinclair Westcott, E. J. Erskine Risk, Donald D. Day, Joseph Armitage, C. H. Bedwell Shears, and Robert S. Batson, of St. Bartholomew's Hospital; Albert Wheeler, Walter Aterbury, and Ernest E. King, of the Middlesex Hospital; Richard Rice and Arthur Hooley, of the Charing Cross Hospital; Arthur H. Proffitt and Richard Vivian, of St. Mary's Hospital; Edward Coterrell, of University College; John W. Batterham, of the Westminster Hospital; H. Pearson Gilbert, of St. Thomas's Hospital; Jonathan Hutchinson, of the London Hospital; Frederick J. Driver, of the Cambridge School; and James M. Chadwick, of the Manchester School.

The following gentlemen passed on April 3rd.

Messrs. Charles P. Lukis, Alexander Haigh, and John H. Stewart, of St. Bartholomew's Hospital; Robert H. Firth, Alexander B. Voisin, and Charles D'A. Collings, of University College; Frank H. Shaw, Benjamin E. Studor, and William W. Pryn, of Guy's Hospital; William A. Duncan and Newton Bentham, of St. Thomas's Hospital; Henry F. Corbould and James Thurton, of the Charing Cross Hospital; Henry J. Minchinton and Thomas W. Scale, of the Middlesex Hospital; Ronald Volkman and Lloyd Francis, of the London Hospital; Herbert F. Parsons and Joseph Tucker, of St. Mary's Hospital; John H. Oates and Joseph Thirkill, of the Leeds School; Charles J. Mouncey, of the Manchester School; and Ernest H. Wagstaff, of King's College.

Nine candidates out of the seventy-two examined, having failed to acquit themselves to the satisfaction of the Board, were referred to their anatomical and physiological studies for three months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, March 28th, 1878.

Bell, William Montague, 362, Camden Road, N.W.  
Fraser, Græme Bisdée, St. Mary's Hospital  
Good, Frederick Thomas, 61, Highbury Hill, N.  
Gover, Henry John, Clapham, S.W.  
Hawks, Robert Shafto, Hertford  
Skelding, Henry John, Bayswater  
Walter, William Henry, Sydenham

## MEDICAL VACANCIES.

The following vacancies are announced:—

ALICE DALE INFIRMARY, Cape Colony.—Obstetric Physician. Salary, £500 per annum, with house, servants, and horse. Applications to be made on or before May 1st to the Physicians and Surgeons of the Hospital, with copies of Diplomas.

ATHY UNION.—Medical Officer of Athy Dispensary District. Salary, £130 per annum, and £15 as Sanitary Officer, together with Registration and Vaccination Fees. Applications to the 9th instant.

ASHTON-UNDER-LYNE DISTRICT INFIRMARY.—House-Surgeon. Salary, £80 per annum, with board and lodging. Applications to be made on or before the 17th instant.

Bournemouth GENERAL DISPENSARY and COTTAGE HOSPITAL.—Resident Medical Officer. Salary, £120 per annum, with rooms, coals, gas, and attendance. Applications to be made on or before the 12th instant.

BRISTOL GENERAL HOSPITAL. Physician's Assistant. Salary, £50 per annum. Applications on or before the 19th instant.

EASTERN DISPENSARY OF BATH.—Resident Medical Officer. Salary, £100 per annum, with furnished apartments, coals, gas, and servants. Applications to be made on or before the 16th instant.

EAST LONDON HOSPITAL FOR CHILDREN and DISPENSARY FOR WOMEN.—Resident Medical Officer. Salary, £60 per annum, with board, lodging, and washing. Applications to be made on or before the 11th instant.

ENNIS DISTRICT LUNATIC ASYLUM.—Resident Pupils. Applicants must be qualified as Physician and Surgeon, and not above thirty years of age. Salary, not less than £50, or more than £60 per annum, with apartments and rations.

GERMAN HOSPITAL, Dalston.—Honorary Assistant-Surgeon. Applications to be made on or before May 1st.

INGHAM INFIRMARY and SOUTH SHIELDS and WESTOE DISPENSARY.—Senior House-Surgeon. Applications to be made on or before the 8th instant.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary, £80 per annum, with board and residence. Applications to be made on or before the 10th instant.

NARBERTH UNION.—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.

QUEEN'S HOSPITAL, Birmingham.—Honorary Physician. Applications to be made on or before the 13th instant.

ROSCOMMON INFIRMARY.—Resident Apothecary and Registrar. Salary, £60 a year, apartment, rations, fuel; or a Non-resident Apothecary to compound the medicines at £30 a year; and a Registrar at £30 yearly. Applications to the 17th instant.

ROYAL CORNWALL INFIRMARY.—House-Surgeon, Secretary, and Dispenser. Salary, £200 per annum, with furnished rooms, coals, gas, and attendance. Applications to be made on or before the 24th instant.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington.—Pathologist and Medical Tutor. Applications to be made on or before the 8th instant.

ST. THOMAS'S HOSPITAL.—Ophthalmic Surgeon. Applications to be made on or before the 6th instant.

WARNEFORD, LEAMINGTON, and SOUTH WARWICKSHIRE HOSPITAL.—House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before the 16th instant.

WOK DISPENSARY.—Resident Medical Officer. Salary, £130 per annum, with furnished apartments, coals, and gas. Applications to be made on or before April 18th.

## MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

BROWN, W. H., M.R.C.S. Eng. (late Assistant House-Surgeon to the Leeds General Infirmary), appointed House-Surgeon to the West London Hospital.

CRESSEY, G. H., M.R.C.S. Eng., appointed Medical Resident and Secretary to the General Infirmary, Hertford, *vice* \*W. Odell, F.R.C.S. Eng., resigned.

WICKS, W. Cairns, M.B., appointed Physician to the Hospital for Sick Children, Newcastle-upon-Tyne.

## BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.*

### MARRIAGE.

FLEMING-WALLS.—At 2, Belhaven Terrace, Glasgow, on the 2nd instant, by the Rev. T. Dobbie, William James Fleming, M.B., F.F.P.S., Lecturer on Physiology, Glasgow Royal Infirmary School of Medicine, to Annie Cole, eldest daughter of William Walls, Esq.

VACCINATION.—Mr. Daniel Gibson, Public Vaccinator for the West District of the Hull Incorporation, has received an award of £69:14 from the Local Government Board for efficient vaccination in his district, this being the second consecutive grant that gentleman has received.

ADDRESS TO MR. G. WYNDHAM MURPHY.—An influential meeting was recently held in the Court House, Ramelton, for the purpose of presenting an address to this gentleman, who has resigned the office of medical officer to the Ramelton Dispensary District. The address, which was in book form and highly decorated, was signed by the magistrates, clergy, and leading inhabitants of the district, and was presented by his numerous friends, who wished to place on record the estimate they had formed of his professional character and personal worth.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### HOW TO EMBALM A BODY.

SIR,—In reply to "Armenia," who asks "How to Embalm a Body," I beg to send you the following description of the process, as given in Johnson's translation of Ambrose Paré's *Surgery*, which was published in 1634.

"But the body which is to be embalmed with Spices for very long continuance must first of all be imbowelled, keeping the heart apart, that it may be embalmed and kept as the Kioskfolks shall think fit. Also the brain, the skull being divided with a Saw, shall be taken out. Then shall you make deep incisions along the arm, thighs, legs, back, loins and buttocks, especially where the greater Veins and Arteries run, first that by this means the blood may be pressed forth: which otherwise would putrefie and give occasion and beginning to putrefaction to the rest of the body: and then that there may be space to put in the aromatic powders the whole body shall be washed over with a Sponge dipped in *agua vite* and strong Vinegar, wherein shall be boiled Wormwood, Aloes, Coloquintida, common Salt and Alum. Then these incisions and all the passages and open places of the body, and the three bellies (i.e., the three great cavities, head, chest and abdomen) shall be stuffed with the following Spices grossly powdered. *R. Pulc. rosar. chamem. melil. balsami. menthar. anethi. salvia. lacend. rorisnar. majoran. thymi. absinthii. cyperi. calami aromati. gentiane. irosos. florent. asse odorata. caryophyll. nuxis moschat. cinnamomi. styracis. calamitiz. benjoini. myrrha. aloes. santal. omnia quod sufficit.* Let the incisions be sewed up and the open spaces that nothing fall out; then forthwith let the whole body be anointed with turpentine dissolved with Oil of Roses and Camomil, adding, if you shall think it fit, some Chymical Oils of Spices, and then let it be again strewed over with the forementioned Powder; then wrap it in a linnen cloth and then in Cere-cloths. Lastly, let it be put in a Coffin of Lead sure soldered and filled up with drie sweet herbs. But if there be no plenty of the forementioned Spices, as it usually happens in besieged Towns, the Surgeon shall be contented with the powder of quenched lime, common ashes made of Oak-wood. For thus the body being over and above washed in strong Vinegar or Lye, shall be kept a long time if so be that a great dissolving heat do not bear sway, or if it be not put in a hot and moist place.

That the embalming may become the more durable, the author further directs the surgeon "to steep the bodies (being imbowelled and pricked all over with sharp bodkins, that so the liquor hindring putrefaction may penetrate the deeper into them) in a wooden Tub filled with strong Vinegar of the decoction of aromack and bitter things as Aloes, Rue, Wormwood, and Coloquintida; and there keep them for twenty days, pouring these into eleven or twelve pints of *agua vite*. Then taking it forth and setting it on the feet, I kept it in a clear and drie place. I have at home" (he continues) "the body of one that was hanged, which I begged of the Sheriff, embalmed after this manner; which remains sound after more than 25 years, so that you may tell all the muscles of the right side (which I have cut up even to their heads, and plucked them from those that are next them for distinctions sake, that so I may view them with mine eyes, and handle them with my hands as often as I please, that by renewing my memory I may work more certainly and surely, when as I have any more curious operation to be performed) the left side remain whole, and the Lungs, Heart, Diaphragma, Stomach, Splene, Kidnies, Beard, Hairs, yea, and the Nails, which being pared, I have often observed to grow again to their form and bigness." As if to dispel any doubts as to his veracity in making this last statement, the author concludes as follows: "And let this be the bound of this our immense labour, and by God's favour, our rest; to whom Almighty All-powerful, Immortal and Invisible, be ascribed all honour and glory for ever and ever. Amen."

In the spelling, italics, etc., I have followed the original.—I remain, yours, etc.,  
12, Colebrook Row, N., March 4th, 1873. GEORGE BROWN.

#### WORMS IN THE OESOPHAGUS OF A DOG.

SIR,—Do the filaræ travel in germ-form with the blood into the viscera? or do they migrate in fully developed state through the tissues from a first point of adhesion in the oesophagus, as the teredo does through a balk of timber? Are they checked in any way in the human subject by a daily ration of alcohol, the habitual use of salt with food, or the habit of smoking tobacco?—Yours truly,  
Jo. C.

#### HEADACHE.

SIR,—It would appear that the headache of J. K.'s patient arises from over-stimulation of an irritable brain. First, there is the "exhilarating" effect of the air of Brighton; second, there is the stimulating influence of the kitchen-fire, to which a cook is necessarily much exposed; third, the food of "the mistress of the kitchen" is generally highly stimulating; and fourth, there are frequently much hurry and excitement in getting meals ready at the proper hour. Now, such an amount of stimulation is decidedly injurious to an irritable nervous system, and is quite sufficient to produce the obstinate and severe headache described by J. K. Sedatives (being merely strong stimulants—i.e., rapid liberators of nervous energy) are decidedly contraindicated. In such cases, I have not found drugs of much avail; excepting, indeed, a gentle laxative, if necessary, every second morning. I deprive the patient, as far as possible, of all avoidable stimulants—viz., tea, coffee, alcohol, and the more stimulating foods, allowing cocoa, fish, rabbit, etc. I disapprove of any food being taken within four hours from bedtime; and I advise the patient to sleep on a high pillow. In such cases, there is frequently great irritability of the heart, which on the smallest provocation sends the blood with severe and sudden force upon the tender brain. To avoid increase of the headache from this cause, I recommend all unnecessary hurry to be avoided, and especially condemn sudden getting out of bed in the morning.

I am convinced that it is only by insisting strongly upon such details that we can be of much service to such patients as that of J. K.; but this method of treatment certainly requires perseverance and self-denial.—I am, etc.,

JAMES MUIR HOWIE, M.D. Edin.

50, Rodney Street, Liverpool, March 25th, 1873.

#### SURGICAL OR PULSE CHRONOMETER.

SIR,—May I ask you and the profession if a watch, constructed so as to beat audibly in unison with the average healthy pulse—say seventy-five—and having a hand describing the full circle of the dial in seventy-five clear movements, in the period of one minute, would be considered an advantage? I imagine it would enable the doctor to time his eye in the light, and his ear in the dark, so accurately as to determine the slightest variations and irregularities of pulsations. At the same time it would, of course, serve the ordinary purpose of time-keeping.—Your obedient servant,  
A WATCHMAKER.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

#### MORTALITY STATISTICS.

SIR,—In reading the weekly accounts of the mortality statistics, I have been puzzled on one or two points, which perhaps you can explain. I can make out very easily that if the mortality at A be 20 per 1000, and at Z 30 per 1000, A must be a much more healthy place than Z. But it seems to me that there is a very important factor always omitted in these estimates which is necessary to a proper understanding of the statistics—namely, the average age of the inhabitants of each of the towns. Every one must die eventually. Let us suppose that each of the towns A and Z started some years ago with a like mortality statistic, and that A, by sanitary or other effort, reduced the death-rate to the lower of the two figures, it is evident that each year there must be an increment of aged persons at A, and this constantly accruing should eventually, after a sufficient interval of low rates, in consequence of the necessary decrease of octogenarian or other aged persons, bring the mortality at A to the level of the mortality at Z.

Again, we have occasional paragraphs that the mortality-rate at particular places is one to so many inhabitants, sometimes going even to hundreds. If this calculation be taken on an area of sufficient extent, or a community sufficiently established, I submit this would show the average age the inhabitants of these places attained. Thus, if it be said that the mortality at N was one in 100, this figure would represent the average age of the inhabitants, which is absurd. I think that when these large figures are presented, it merely proves that the register of mortality has been very imperfectly kept.—Yours, etc.,  
G.

Our correspondent's difficulty in comprehending the true bearing of mortality statistics is not an unusual one. The influence of the age distribution of a population upon its rate of mortality has been at the same time both overrated and misunderstood. The influence is, for all practical purposes, in actual populations, so small that it may almost be disregarded when comparing mortality statistics. The age constitution of a population depends, moreover, fully as much upon the birth-rate as on the death-rate. Our correspondent overlooks the fact that, if a death-rate decline and the birth-rate be maintained, the proportion of children and young persons in the population will increase at a greater ratio than that of the elderly persons—supposing that the birth-rate exceeds the death-rate, which is almost invariably the case.

In the second part of his letter, G. is evidently thinking of a stationary or life-table population. An annual rate of mortality equal to one in 100, or 10 per 1000, maintained throughout a generation, would undoubtedly, in a stationary population, signify a mean duration of life of one hundred years. This is, however, not the case in actual populations which are increasing populations. A death-rate in a single year so low as 10 per 1000 has no possible connection with the mean duration of life, neither does it afford any evidence that the death-register is imperfectly kept, which is now almost impossible.—ED. BRIT. MED. JOUR.

#### PHYSICIANS' FEES.

SIR,—The animated discussion of the proper remuneration of professional services prompts the question, Whether any scheme involving a fixed fee for every visit or consultation be fair to either the patient or the physician? If we maintained the poetic fiction that our aid, being immeasurable by pecuniary standards, was given to mankind out of pure philanthropy, and that the *honorarium* was a spontaneous testimonial of gratitude, apportioned to the patient's means, the present system might be defended from an Arcadian point of view; but in this prosaic and practical nineteenth century, the public, if not the profession, have learned to look upon medical attendance as a business affair, regarding a fee as payment for value received. In all other matters of exchange, political economy teaches that the price is regulated by the amount of service rendered: even where no barter of material commodities takes place, this rule obtains; as, for example, in the legal profession, where the charge for an opinion is proportioned to the importance or difficulty of the case. In medicine alone do men adhere to the traditional absurdity of an unvarying fee for each interview, irrespective of the thought and skill exercised therein—whether it concern the most intricate question of diagnosis, or the routine prescription of a cough-mixture. It is not an uncommon event in medical practice to be able, on the one hand, to save a life by a single visit, or, on the other hand, to have for some days under treatment a comparatively trivial ailment which neither imperils life nor taxes professional skill. In which of these cases is the larger reward fairly earned? Another objection to the system of stated charges "for each consultation or visit" (setting aside the remote possibility of a physician being so unprincipled as to yield to the temptation to multiply unnecessary visits) is, that it establishes an inverse ratio between a physician's skill and his compensation; the more speedily he cures his client, the smaller being his aggregate reward. If it were left to the patient's option, most people would cheerfully pay more to be made well in a week than to be kept ill for a month; but, under the existing plan, the doctor who is fortunate enough to cap a mistaken diagnosis with inadequate therapeutic measures makes four times as much as his clever colleague, whose work is successfully done with one-fourth of the number of visits. Even in the inner circle of consultants and specialists who enjoy great popular celebrity, errors of diagnosis and failure of treatment sometimes occur; and it may happen that a patient who has paid frequent but futile visits to one adviser, will obtain relief from one or two consultations with another. Ought the former's failure to be more profitable than the latter's success?

Unless we are willing to place ourselves on the same economic footing as the manual labourer, who is paid for his time without regard to the kind of work he does, I would suggest that we accept our modern relation to the business-like community, and make our charges proportionate to the value of the service which we render in any given case, rather than to the number of visits made. In my own practice I have been guided by this principle for some years, and have found it to work generally to the satisfaction of my patients and myself.—I am, sir, yours, etc.,  
AN AMERICAN PHYSICIAN.

#### OLEATE OF BISMUTH.

SIR,—In 1876, an oleate of bismuth was prepared for me by Messrs. Hopkins and Williams; and subsequently I wrote a paper on its properties and uses, which was read at a meeting of the Pharmaceutical Society, and reported in their Journal (No. 357, December 9th, 1876). I now wish briefly to state that I have repeatedly employed this compound in cases of eczema and pityriasis (simplex) with sufficient success to induce me to draw attention to it in these columns, in the hope that others may give it a trial.—I am, etc.,  
LOUIS LEWIS, M.D.

## A CURE OF EPILEPSY.

IN connection with a letter from A. H. D., it is our duty to draw attention to the following documents, forwarded at the same time, and since in duplicate by other correspondents.

*Fits.—Epileptic Fits or Falling Sickness*—A certain method of cure has been discovered for this distressing complaint by a physician, who is desirous that all sufferers may benefit from this providential discovery. It is never known to fail, and will cure the most hopeless case after all other means have been tried. Full particulars will be sent by post to any person free of charge.—Address—Mr. Williams, 10, Oxford Terrace, Hyde Park, London.

This is an advertisement from a weekly paper. In response to a reply to the advertisement were forwarded the following lithographed circulars.

"London.

"In accordance with the wish expressed in your favour, I am directed to send you Dr. Niblett's treatise on various diseases, in which you will find full particulars of the preparations used. A clergyman, whose son has been cured by the medicines, has published an edition of ten thousand copies of this treatise, and he has instructed me to send a copy to any one who may wish it. Should you or any of your friends require the doctor's advice, I am desirous to say he will be happy to reply to any letters free of charge.—I am, your obedient servant, W. WILLIAMS."

"London.

"Your letter has been handed to me by Mr. Williams, and I have directed him to forward you one of my treatises, which I hope you have received safely. Should it, however, by any mishap have been delayed or lost, I shall have much pleasure in sending you another by return of post, on receiving an intimation from you to that effect. I take this opportunity of enclosing you a few of my printed forms, to fill up in case you or any of your friends should desire to place yourselves under my treatment; in which case you will find it convenient to fill up one of the enclosed forms and return it to me.—I am, yours faithfully, S. BERRY NIBLETT."

There was also forwarded a copy of a pamphlet *On a Rational Method of Treating Consumption, Chronic Bronchitis, Asthma, and all Diseases of the Lungs, Liver, and Heart. Also a Treatise on Epilepsy and Fits: with Practical Observations on many Prevalent Diseases.* By S. Berry Niblett, M.D., Royal College of Physicians. One part of the pamphlet runs thus:

*Treatment of Consumption.*—In recommending the following treatment, I trust that I am actuated by an earnest desire to benefit those whose cases it may serve to illustrate. My aim is to lessen human suffering and to prolong human life.

"Blessed art of healing, once again divine."

The specific medicine which I have so successfully prepared for every form and variety of consumption, and all disease of the lungs and air-passages, is called *The Restorative Balm*. There is not a single symptom of consumption that this balm will not take hold of and eradicate. Its action is immediate; it will also remove chronic bronchitis, asthma, sharp pains in the chest, difficult expectoration, sore throats, coughs, and colds, also general debility. It will nourish and strengthen the vital organs by purifying the blood and removing all nervousness; it will greatly assist the digestive organs and increase the appetite; it will itself nourish the patients for weeks at a time.

On page 16 the following passages occur:—*"Treatment of Epilepsy.*"—Heed not the twaddling of ignorance, but listen to the voice of judgment and experience.—After several years of experiment and research, I have been enabled to discover a certain remedy for all forms of epilepsy and fits; it is called *The Vital Renewer*. This invaluable remedy will cure the most inveterate cases, even when the fits have lasted for years. None need, therefore, despair. It is perfectly harmless; it is prepared exclusively by myself, and no cost has been spared to bring it to the specific remedy it now is.

From this the whole of the pamphlet may be inferred. In the *Medical General Register* is the following entry:—"1859, January 1st, Niblett, Stephen Berry, 10, Oxford Terrace, Hyde Park, London, W.; Lic. Soc. Apoth. Lond., 1858; Lic. R. Coll. Phys. Edin. 1860; Lic. Fac. Surg. Glasg., 1861."

The profession will be interested to know whether the licensing bodies in question are disposed to allow this to pass unnoticed much longer.

## MENSTRUATION AND THE CURING OF MEAT.

SIR,—The question asked by your correspondent in the JOURNAL of March 2nd has just been recalled to my mind. Last week, I ordered a pig to be killed, but the cook demurred, and made excuse about not being able to attend to the curing. My wife afterwards informed me that she objected because she was in a "certain way." The killing was therefore postponed. This was a *hog* pig. The next day, my men remarked that I must not think of killing the sow, as she was "brenming," and therefore would not take the salt. I have, then, in my establishment two persons firmly asserting two distinct facts—that the hams and bacon will not cure if the rubber be menstruating, and that if a sow be killed when "brenming" it will not take the salt. During the past few days, I have spoken to several matrons about the opinion, who all believe firmly in it. One person had a number of hams spoiled through the thoughtlessness of the cook; and since then she has had them rubbed by a man. I may say that this belief is not peculiar to a locality. I knew it to be held in the north and south of England. I have only heard one explanation—the moisture that is on the hands and body during the catamenial period. This matter might be decided by experiments made in lunatic asylums or prisons, under the direction of the medical officers.—Your obedient servant,

March 12th, 1878.

## THE BRUSSELS DEGREE.

SIR,—In answer to the inquiries that are being made regarding this degree, permit me to give a slight sketch of the conditions on which it may be obtained and the nature of the examinations, as I have been in Brussels lately and taken the degree. The candidates must hold a diploma in medicine and surgery, and produce the same to the secretary before the first examination. He must matriculate; the fee is £8 12s. It entitles him to attend all the lectures in the Faculty of Medicine, and the clinics at the hospitals, St. Jean and St. Pierre, for the year. He must pay the examination fees, four guineas for each examination, or twelve guineas in all. Forty-eight hours after matriculation he may go up for the first examination. It consists of the following subjects, 1. Special Pathology; the examiner is Professor Crocq; 2. General Pathology, Professor Desmech; 3. Pathological Anatomy, Professor Whankel; 4. Materia Medica and Therapeutics, Professor Van den Corput. If he pass this test, he receives a certificate to that effect, and forty-eight hours afterwards he may go up for the second. The following are the names of the examiners and the subjects. Surgery and Surgical Pathology, Professor Thiery; Midwifery, Professor Pigeolet; Forensic Medicine, Professor Guillery; Hygiene, Professor Mahaux. Forty-eight hours after passing this examination, he may go up to the third and final. Clinical Medicine, Professor Crocq; Clinical Surgery, Professor De Roulaix; Operative Surgery, Professor Tirifay; Operative Midwifery, Professor Pigeolet. If a candidate fail in the first test, he is re-

funded eight guineas; if he pass the first and fail in the second, he is refunded four guineas; if he fail in the third, there is no money refunded, but by paying an extra guinea at any time within twelve months he can come back again and have another trial. Some of the professors speak English, and examine the candidates in that language, but most do so through an interpreter. The only special book that I would recommend is Parkes's *Manual of Hygiene*. The ordinary text-books used do well enough. The subjects that most men are weak in are pathology, hygiene, and anatomy.

Intending candidates should write to Dr. James, 10, Rue de Luxembourg, Brussels. He is Professor of Latin, and, being an Englishman, generally acts as interpreter. He informed me that the percentage of rejections about three or four years ago was only five per cent.; during the last year it has been about thirty-three per cent., or one in three. The examinations are public; and a gentleman who is a F.R.C.S. came over for examination, and was present during two of the days that I was being examined. He saw that the tests were more stringent than he expected, and determined to remain and read up for a week or two before going up. I took notes of all the questions asked; and if you think they would be of any use, I will forward them for publication.—I am, faithfully yours,

March 1878.

C. B. G.

THE following communications have been handed to the General Manager:—Dr. J. Smith, Dumfries; Mr. P. J. Gill, Birmingham; Mr. H. S. Worsley Benson, London; Mr. James Kirkeley, South Shields; Mr. H. S. Beaufort, Lym; Mr. T. H. Wilson, Montrose.

# THE GOULSTONIAN LECTURES ON THE LOCALISATION OF CEREBRAL DISEASE.

*Delivered at the Royal College of Physicians of London.*

By DAVID FERRIER, M.D., F.R.S., F.R.C.P.,

Professor of Forensic Medicine in King's College; Assistant-Physician to King's College Hospital; etc.

## LECTURE II (concluded).—March 20<sup>th</sup>.

**Brachio-Cranial Monoplegia.\***—Paralysis of the leg occurs more frequently in association with paralysis of the arm than singly as the result of cortical lesions. I have already given several cases of this kind, to which the following may be added.

MM. Charcot and Pitres† give a case of paralysis with rigidity of the left limbs of three years' duration, sensibility being unimpaired. A patch of softening  $5 \times 2.5$  centimètres was found at the upper extremity of the fissure of Rolando, on the convex surface of the right hemisphere. (Fig. 18.)

M. Moutard-Martin‡ reports a case of fracture of the skull and injury of the brain, causing paralysis of motion of the right arm and

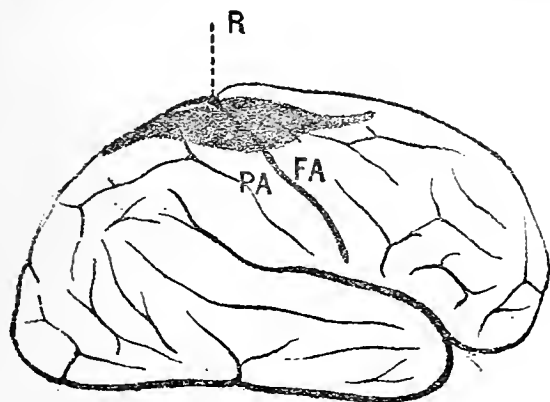

Fig. 18.

leg, for which trephining was practised without success. The cerebral lesion occupied the upper extremity of the ascending frontal, ascending parietal, and anterior two-thirds of the postero-parietal lobule, and slightly to the inner aspect of this region, or paracentral lobule.

M. Pitres§ gives a case in which the lesion affected, not the cortex, but the medullary fasciculi of the superior frontal and parietal region.

**Brachial Monoplegia.**—The centres for the movements of the arm and hand occupy a considerable space, as might be expected from their importance as organs of intelligence. Area [5] (figs. 15 and 16) is the centre for the forward extension of the arm and hand; area [4], for the adduction and retraction; area [6], for the supination and flexion; while the various letters (*a, b, c, d*) placed in the ascending parietal convolution indicate the portion of the various centres for the movements of the wrist and fingers. With these latter, retraction of the angle of the mouth is apt to be associated, owing to the proximity of the facial and oral centres (7, 8, 9, 10, 11, fig. 15): a proximity which serves to explain, among other things, the retraction of the angle of the mouth so commonly seen associated with powerful action of the hand. Hence also the fact that brachial monoplegia occurs less often than brachio-facial paralysis.

It is obviously highly important, in any given case of brachial monoplegia of cortical origin, to determine, if possible, which of the movements of the upper extremity are particularly affected. This has not been done with any great degree of accuracy in many of the recorded cases.

M. Maurice Raynaud|| reports a case of paralysis limited to the left

arm, and more particularly to the extensor muscles, though the flexors were also paretic. There was no diminution in sensation, nor alteration in electro-motor contractility. The lesion was situated in the ascending parietal convolution of the right hemisphere, in the position of a line drawn back from the second frontal. It was an area of softening surrounding a tubercle of the size of a millet-seed, and about a centimètre in diameter; the softening affecting the subjacent medullary fibres more than the cortex. A smaller area of softening of the size of a pea was situated near this, but within the fissure of Rolando. The whole lesion could be covered with the pulp of the finger.

M. Sabourin\* records a case of sudden partial right hemiplegia without loss of consciousness, which soon disappeared, leaving paralysis of the right hand and arm, which continued till death seven days afterwards. A focus of red softening was found in the left hemisphere of the size of a two-franc piece, the centre of which, where the softening was greatest, corresponded with the junction of the ascending parietal convolution and supramarginal lobule. The softening extended halfway up the ascending parietal convolution, somewhat concealed within the fissure. The ganglia were intact.

M. Boyer† has recorded a case of sudden paralysis of the left arm and leg. After four or five days, the leg regained its power, while the left arm remained permanently paralysed. The affection happened in 1872. In 1877, the condition was rigidity of the left arm and atrophy of the muscles of the forearm. Sensation was unimpaired. The patient died of bronchopneumonia. The left hemisphere was normal. In the right hemisphere, a patch of atrophy, caused by an old yellow softening, existed in the ascending parietal and ascending frontal convolutions; and an extension of the same existed in the temporo-sphenoidal region. The position of the lesion is indicated, from a drawing sent me by M. Boyer, in the diagram before you.

M. Bourdon‡ has collected several other cases, from which I quote the following.

A case related by M. Pierret, of an apoplectic attack with early rigidity of the left arm and retraction of the right angle of the mouth, followed by partial paralysis of the left arm. Death occurred twelve days afterwards, from sudden coma and epileptic convulsions. In the right hemisphere, at the junction of the middle frontal with the ascending frontal convolution, a focus of red softening of the size of a franc-piece existed. A similar focus existed in this case in the median occipital of the same hemisphere.

Another case, observed by Darolles, is given, of cerebral affection resolving itself ultimately into paralysis of the right arm. A hæmorrhagic extravasation was found in the left hemisphere, embedded in the cortical substance, three millimètres in extent, at the upper part of the ascending parietal convolution. A patch of softening also existed in the median occipital lobe of the right hemisphere in this case.

In a third case, there was an association of aphasia with paralysis of motion of the right arm. The brachial monoplegia continued till death. After death, a small hæmorrhagic extravasation was found at the upper part of the ascending frontal convolution of the left hemisphere.

M. Bourdon also quotes an interesting case of double brachial monoplegia communicated to him by M. Vermeil. This was the result of a cranial injury. The arms only were paralysed as to motion, sensation being unimpaired. Death occurred two days after the accident. There was no depression of the skull at any part. On the surface of the brain were two small superficial hæmorrhagic extravasations of about fifteen millimètres in diameter. The one of these was situated towards the upper part of the ascending frontal in the left hemisphere. The other, in the right hemisphere, was situated at the junction of the ascending parietal with the supramarginal lobule.

Several other cases of brachial monoplegia (Raymond's, Demongéot de Confrevon's) are on record; but the characters of the lesions (tuberculo-meningeal) are not altogether such as to admit of their being quoted as exactly circumscribed. I will only refer to one other case of brachial monoplegia, respecting which there exists some doubt as to its harmony with the other facts related in reference to limited paralyses. The case is related by M. Cotard.§ A woman, who died at the age of seventy-one, had been seized with convulsions, followed by paralysis of the left arm, about the age of two years. The left arm continued paralysed and rigid. She walked with difficulty; but this was apparently due to fracture of the neck of the left femur a few years before. Formerly no difficulty was noted in this respect. The right hemisphere was smaller than the left. "Behind the upper extremity of the fissure of Rolando, there was a longitudinal depres-

\* I use the term monoplegia here to indicate paralysis of a distinct group of movements, and not as meaning paralysis of a muscle or a limb.

‡ Op. cit.,

§ Atrophie partielle du Cerveau, p. 21.

sion of the cortex, which extended parallel with the longitudinal fissure as far as the occipital lobule, five *centimètres* in length by one *centimètre* in breadth." It is not clear in this case what extent of the ascending parietal convolution was involved, or how much of the postero-parietal lobule, if any, as it is only said that the linear depression was parallel to the longitudinal fissure. M. Charcot, in whose *clinique* the case occurred, is unable to give me further particulars as to the exact seat of the lesion. The uncertainty in this case is as regards the extent of the affection of the centre for movements of the leg, which, whether they were affected at first or not, do not seem to have been permanently so.

A somewhat similar uncertainty also exists in reference to Boyer's case already quoted, in which, though the leg was at one time paralysed, yet recovery took place, though some lesion of the leg-centre still appears to have continued. It is, therefore, a question whether the leg may regain complete power, notwithstanding the existence of partial lesion of its cortical centre. These cases would seem to indicate this, granting always that the observations were thoroughly exact and minute.

M. Charcot, in a private communication to me respecting Cotard's case, thinks that cortical lesions in infancy do not have precisely the same effect as similar ones in the adult, owing to the functions of the cortical centres not being as yet well defined. This is worthy of particular investigation, and would seem to be justified by the experiments of Solimann in reference to the development of the cortical centres in young animals.\*

With the exception of Cotard's case, which must remain doubtful, the seven cases I have quoted of limited lesions with brachial monoplegia are entirely in harmony with the localisation of the head and arm centres in the monkey; for, though the lesions recorded did not occupy the same position in all, yet they were all in regions included within the area in which these centres are situated, viz., the ascending parietal and upper part of the ascending frontal convolutions.

In those in which it was noted that the hand in particular was affected, the lesion invaded the ascending parietal convolution, in accordance with the facts of experimental localisation. In others, no differentiation was made, or was possible. It would have been most interesting if this had been done in Vermeil's case of double brachial monoplegia, as the lesions occupied centres for different movements of the upper extremity.

As with the leg, so also in regard to the arm, some cases of amputation, or congenital deficiency, of the hand or arm are on record in which atrophy has been described in certain convolutions of the opposite hemisphere.

A case is reported by Chuquet† of amputation of the right arm six years before death. In the left hemisphere, there was atrophy of the upper third of the ascending parietal convolution and corresponding part of the internal surface of the hemisphere. The length of the atrophied part was two *centimètres*.

M. Boyer‡ examined the brain of a man who died at the Bicêtre, having had his left arm amputated thirty years previously. The ascending convolutions were atrophied at their superior extremity, and the ascending frontal was throughout very slender and flattish.

Dr. Gowers has kindly given me the particulars, accompanied by a photograph of the brain, of a case of congenital absence of the left hand. The middle part of the ascending parietal convolution in the right hemisphere is, as clearly shown in the photograph, much smaller than the corresponding convolution in the left. A microscopic examination had not been made at the time Dr. Gowers gave me these particulars, though he intended carrying this out.

The cases of atrophy—and of these Dr. Gowers's seems the most satisfactory, inasmuch as the lesion was congenital—if we cannot place absolute reliance on them as yet, are not opposed to the localisation of the hand and arm centres as determined by physiological experiment or the facts of disease.

**Brachio-facial Monoplegia.**—The combination of brachial with facial paralysis is a much more frequent occurrence than brachial or facial paralysis singly in connection with cortical disease; and very commonly, and for obvious reasons, it is associated with aphasia when the disease is in the left hemisphere. This, however, is not always the case; and I have recently seen two cases of right brachio-facial monoplegia without aphasic symptoms. Many such occur, but recover and are lost sight of. *Post mortem* examination has, however, been made in several.

Dieulafoy§ has recorded the case of a woman, aged 60, who was sud-

denly seized with paralysis of motion in the right arm and right lower facial region. Death occurred the next day from coma. The necropsy revealed a hæmorrhagic extravasation, of the size of a nut, surrounded by a zone of softening in the ascending frontal convolution of the left hemisphere. The exact position of the lesion in the ascending frontal is not given more accurately in the record.

Troisier\* gives a case of a man, who died of phthisis, who had been suddenly seized with paralysis in the right arm, at first showing itself in the muscles supplied by the musculo-spiral nerve, and followed by complete paralysis of the limb, with the addition of right facial paralysis; sensation was intact. In the left hemisphere, a patch of hyperæmia and yellow granulations, of seven to eight square *centimètres* in extent, was found posterior to the third frontal convolution. The lesion was not very definite in this case, and it was further complicated by the simultaneous occurrence of granulations in the membranes behind the posterior parietal convolution.

M. Hippolyte Martin† has recorded a case of left facial paralysis, with paresis of the left arm, more particularly shown in the first three fingers. The affection had come on suddenly, without loss of consciousness or other paralysis, five or six months previously. The necropsy revealed a patch of yellow softening in the lower fifth of the ascending parietal convolution of the right hemisphere. The softening extended up the fissure of Rolando, to a level with the posterior extremity of the second frontal convolution. The softening penetrated about one *centimètre* from the surface. The basal ganglia and the rest of the brain were normal.

Crucilhier‡ gives a case, illustrated by a figure, of paralysis suddenly occurring on the right side of the face and tongue (aphasia), with paralysis and rigidity of the right arm. The lesion in this case was a patch of red softening of about  $2 \times 4$  *centimètres* in extent, situated at the lower third of the fissure of Rolando, and affecting also very specially the ascending parietal convolution.

A case reported by Anton Frey§ is referred to by M. Pitres||, as showing that brachio-facial monoplegia may occur from lesions limited to the medullary fibres of the middle pediculo-frontal and frontal section. The symptoms were paresis of the left arm and left side of the face, without affection of sensation. Death occurred from gangrenous erysipelas of the face. In the right hemisphere, a small focus of hæmorrhage, formed by the juxtaposition of three minute extravasations, each of the size of a mustard-seed, was found in the medullary fibres at the junction of the middle frontal with the ascending frontal convolution.

Other similar cases are given by Pitres, which I need not, however, quote. I might cite many other instances of this form of monoplegia in connection with cortical lesions; they are not, however, all described with the degree of topographical accuracy which is desirable. I would refer the reader to M. Landouzy's work, where most of them are collected and details given, and also to Grasset's recent memoir, *Localisation dans les Maladies Cérébrales*, 1878.

A glance at the diagrams before you, and a comparison of the position of the lesion in these five cases with the situation of the hand and facial centres (areas [7] [8] [11], fig. 15), will show how close is the correspondence between them. The lesions causing brachio-facial monoplegia are all towards the middle of the ascending frontal and parietal convolutions or somewhat lower, regions which include facial and brachio-manual centres, as indicated by experimentation on monkeys.

**Facial Monoplegia.**—Facial paralysis of the cerebral type—i. e., paralysis limited almost exclusively to the lower facial region—is not a very common occurrence by itself in connection with cortical disease. Usually, it is complicated with brachial paralysis or with aphasia; with the latter more especially when the lesion is in the left hemisphere. This is naturally to be expected from the proximity of the facial centres ([7] [8], fig. 15) to those of the arm and hand already indicated, and to the lingual and oral centres ([9] [10] [11], fig. 15).

Brown-Séquard\* reports a number of cases of facial paralysis, "seemingly caused" by lesions in various parts of the brain, such as the frontal, occipital, and temporo-sphenoidal lobes; but as there is not even a common, to say nothing of a constant, relation between such lesions and motor paralysis of any kind, and as there seems to have been no attempt at distinction between peripheral and central facial paralysis, the facts have little or no value as regards localisation.

The cases on record in which paralysis limited to the face has been

\* *Jahr. für Kinderheilk.*, Band ix.

found in connection with localised cortical disease have been due to lesion of the right hemisphere; but in none can the lesion be said to have been accurately defined or uncomplicated. Charcot and Pitres\* give a case, with a figure (fig. 19), of a lesion, extensive in one sense, but limited as regards the motor area of the brain involved. This was

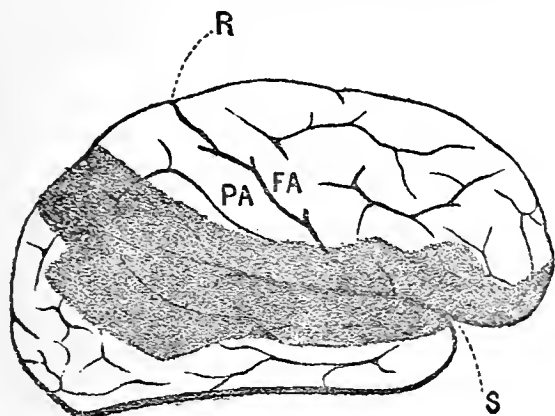

Fig. 19.

a case of apoplexy with facial paralysis and early rigidity of the limbs on the left side. The rigidity of the limbs disappeared, but the facial paralysis persisted till death. An extensive area of softening was found in the right hemisphere, invading the third frontal, the lower extremities of the ascending convolutions, and a large extent of the parietal, temporo-sphenoidal, and insular lobes.

Hitzig† relates the case of a French soldier, who, two months after a bullet-wound on the right side of the head, began to be affected with clonic spasms in the left side of the face. These were followed by transient, but complete, paralysis of the left side of the face and left side of the tongue. Clonic spasms occurred also in the left hand. After death, an abscess was found corresponding to the seat of the injury, situated in the ascending frontal convolution, between the pre-central fissure and the fissure of Rolando. It should, however, be noted that there were indications of meningeal inflammation over the whole surface of the right hemisphere, though there was no cerebral softening except in the neighbourhood of the abscess. A similar case is reported by Wernher‡. Had the lesions been in the left instead of the right hemisphere, we should in all probability have had the symptoms of aphasia superadded, as in the following case—to select one from a host—related by Hervey.§ This was a case of right facial paralysis with aphasia. A focus of softening was found anterior to the fissure of Rolando, at the junction of the third frontal with the ascending frontal convolution of the left hemisphere.

Dr. Gowers|| has reported a case of left hemiplegia, which gradually recovered, with the exception of very marked paralysis of the inferior facial muscles. Under the influence of emotion, however, the muscles acted equally well on both sides. This was found to depend on a hæmorrhagic extravasation in and beneath the upper half of the pre-central sulcus, which had pressed upon the convolutions bounding it—viz., the posterior extremity of the middle and superior frontal, and corresponding part of the ascending frontal of the right hemisphere.

**Aphasia—Oro-lingual Hemiparesis.**—I would now make a few remarks on what may be described as an objective-subjective monoplegia; in the one aspect, oro-lingual hemiparesis; in the other, aphasia. It is not my intention to discuss the intimate pathology of aphasia, nor the relation between the objective and subjective aspects of the lesion on which this depends. Nor do I think it necessary, in the present state of clinical medicine and pathology, to take up time with the enumeration of instances of aphasia with lesions in what is termed Broca's region.

The occurrence of aphasia in the immense majority of instances in connection with disease of the left hemisphere and with disease in a region which, as you will see by reference to the diagrams, corresponds with the oral and lingual centres in the monkey ([9] [10] figs. 15 and 16), is a fact which can no longer be disputed. It is also a fact that, in the great majority of instances, aphasia is associated with a greater or less

degree of right hemiplegia or right monoplegia, of which the most common is brachio-facial or facial monoplegia.

It is necessary that those who dispute the validity of inferences as to causal relationship between the lesions indicated and aphasia, should clearly understand what is contended for by those who consider this relationship established. Aphasia, in the strictly limited sense of the term, or Broca's aphasia, does not mean speechlessness from paralysis of articulation, nor speechlessness from general cerebral disturbance, such as emotional shock, etc., but the inability to express thoughts in articulate speech, or to think in words, and all that this implies.

It is not contended that there is an absolute restriction of the speech-centre to the left hemisphere. This, though the rule, is not an absolute rule, but only an approximate generalisation, and therefore exceptions may be admitted without invalidating the localisation of the speech-centre in one side or the other, which is what is really maintained. Hence, to overturn the localisation of a speech-centre, it is not enough to bring forward a case of lesion of the left speech-centre without aphasia. This is admitted by all; and it is a very significant fact, that in several at least of the cases of aphasia with disease of the right speech-centre, the patients have been left-handed.

It is incumbent upon the opponents of this localisation to bring forward a case in which, with bilateral lesion of this centre, no aphasia occurred. But, I need scarcely say, no such evidence exists.

The effect of a bilateral lesion would be, according to the results of experimental physiology, both aphasia and anarthria, or paralysis of articulation.

A beautiful, and I believe an unique, instance of this has been put on record by Dr. Barlow.\* A boy aged 10, the subject of aortic disease, of which he ultimately died, was seized with right hemiplegia, chiefly brachio-facial, and aphasia. Of this he had apparently recovered at the end of a month. Three months afterwards, he was seized with left brachio-facial monoplegia. This time there was not only aphasia, but paralysis of all voluntary movements of the mouth and tongue. Reflex deglutition, however, was unimpaired. There was no affection of sensation in the paralysed parts, either in the skin or in the mucous membranes of the palate, etc., and the muscles reacted normally to the faradic current. "To sum up the cerebral condition", says Dr. Barlow, "there appeared to be loss of voluntary motor power over the muscles concerned in deglutition and articulation." This lasted till death, while the arms improved somewhat in power. Intelligence was fair, and comprehension good. On *post mortem* examination, a lesion was found in each hemisphere, and in exactly corresponding situations. The region involved by the lesion—which was yellow softening—was

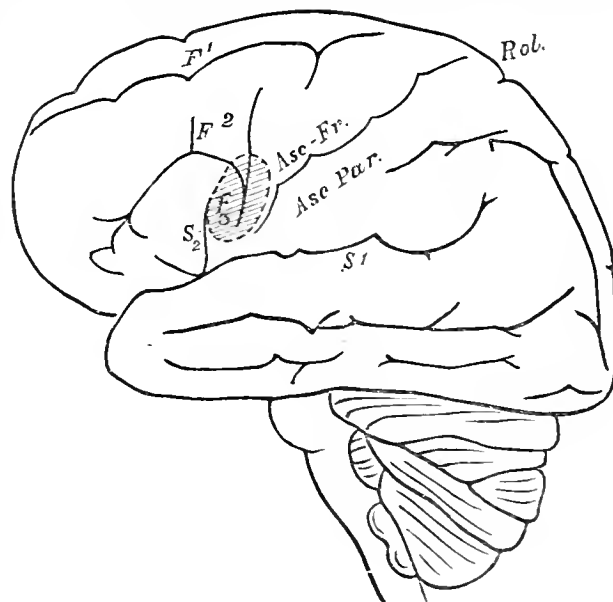

Fig.

"the lower end of the ascending frontal and the hinder end of the middle and inferior frontal convolutions". (Fig. 20.)

This case, in all its features, whether we look at it as an experiment

\* *Revue Mensuelle*, 1877, p. 181.

|| *Pathological Transactions*, 1876, p. 35.

of disease, approaching to the conditions of an exact and precise experimental lesion, or to the care with which it was observed and distinguished from peripheral or bulbar paralysis, is one of the most satisfactory and conclusive demonstrations of the harmony between human pathology and experimental physiology with which I am acquainted.

Some ingenious—if we cannot call them successful—attempts have been made to overthrow the causal relationship between lesions in Broca's region in the left hemisphere and aphasia, and to make it a relationship merely of co-existence.

As embolism or thrombosis of the left middle cerebral artery or one of its branches, is perhaps the most frequent cause of aphasia, it has been suggested by Jaccoud and others, that the greater frequency of aphasia with left cerebral lesion might be accounted for by the greater frequency of embolism in the left middle cerebral artery than in the right. That this is so appears to be an indisputable fact, and perhaps to be accounted for by the physical conditions of the blood-supply. Meissner\* found in 38 cases of embolism, 26 in the left and 12 in the right; and Bertin found 31 cases of embolism of the left to 7 of the right middle cerebral. Aphasia, however, does not always depend on embolic softening; and if we take the relative frequency of softening due to any cause, in the right and left hemisphere respectively, we find, according to Andral's statistics, that the right hemisphere is more liable than the left. Thus out of 169 cases, 73 were in the right, 63 in the left, and 33 in both hemispheres. And in reference to diseases of the hemispheres generally, Charcot and Vulpian found the relative proportions in the two hemispheres very nearly equal. They found 58 cases of left hemiplegia with disease of the right hemisphere, to 52 cases of right hemiplegia with disease of the left. As regards the relative frequency of aphasia with right and left hemiplegia respectively, Seguin found, from an analysis of 266 cases of hemiplegia with aphasia, 243 with right hemiplegia, and 17 with left hemiplegia; i.e., a proportion of 14.3 : 1. Now, if we take Bertin's statistics as to the relative proportion of embolism of the left and right middle cerebral as 4.4 : 1, and Seguin's association of aphasia with lesion of the left hemisphere as 14.3 : 1, we have, in favour of the association of aphasia with lesion of the left hemisphere, a preponderance of 10 : 1, which cannot be accounted for by mere fortuitous collocation; and even if the arguments founded on the relative frequency of disease in the left and right hemisphere respectively, had not been thus shown to be without foundation, they would be at once disposed of by cases of aphasia resulting from traumatic lesions of the left hemisphere. Several interesting cases of this kind are on record.

Sydney Jones† gives a case of aphasia resulting from fracture of the left side of the skull by the kick of a horse. After death, an abscess of the size of a nut was found in the medullary substance of the third left frontal convolution.

Simon‡ gives a case of a healthy man who fell from horseback, and who on getting up was found by a physician who came up to be aphasic, and without any signs of paralysis. Death occurred from meningitis. A small wound with depressed fracture of the left side of the skull was found; and corresponding to this was a cerebral softening—surrounded by meningeal inflammation—of the third left frontal (in which a spiculum of bone was imbedded), the second frontal, and the island of Reil.

A similar case of aphasia from fracture of the left side of the skull, in which recovery took place on trephining, has been recorded by MM. Proust and Terillon.§

That gross anatomical lesions have not always been discovered in Broca's region in cases of aphasia may be true, but this is a fact of no value against the localisation of the speech-centre here. Perhaps they might have been discovered more frequently if careful search had been made, for on more than one occasion they have been found, when supposed absent, in the subjacent medullary fibres. Of instances of this kind several have been collected by M. Pitres.

The clinical evidence alone is amply sufficient to establish the relation between aphasia and lesion of Broca's region as an empirical generalisation; but when we take into consideration also the facts of experimental physiology and the light they throw on the motor substrata of mind, the connection between lesion of Broca's region and aphasia is no longer a merely empirical generalisation, but a derivative law, which in my opinion is established on as firm grounds as any other fact in scientific medicine.

*Diagnosis of Cortical Paralysis.*—Apart from considerations as to the mode of onset, etc., of the affection, there are no features which clearly enable us to distinguish between hemiplegia depending on general destruction of the motor area of the cortex, and hemiplegia due to destructive lesions of the corpus striatum, more particularly those involving the anterior two-thirds of the internal capsule. There is the same relative affection of the different movements; those being most paralysed which are most volitional, at least after the first rude shock of the disease has subsided. The facial paralysis is seen especially in the lower facial region, or in those movements which are most independent; while the frontal and the orbicular muscles of the eye are but slightly affected. The movements of the leg are less paralysed than those of the arm, and the proximal movements of the arm less than those of the hand. In neither case is sensation affected, if the lesion be strictly limited to the cortex, or to the anterior two-thirds of the internal capsule; and in neither case is the nutrition or electric contractility of the paralysed muscles directly impaired. The same tendency exists in the development, sooner or later, of descending sclerosis of the motor tracts of the crus, pons, medulla, and spinal cord, and the appearance of late rigidity or contracture of the paralysed limbs. This late rigidity seems, according to the views of Charcot, Bonchard, Bastian, etc., to be essentially dependent on the degenerative process, and has its analogue in lateral sclerosis of protopathic origin. Hughlings Jackson, however, looks on late rigidity as a species of tonic distortion, caused by the cessation of the cerebral influence, and the consequent unopposed action of the cerebellar and mesencephalic centres; for, says he, "there is unimpeded cerebellar influx, and hence rigidity of the muscles which in health the cerebrum chiefly innervates".\* I see serious objections to this view. If it were true, I should expect the antagonism or cerebellar influx to show itself at the beginning of the paralysis; for distortion, consequent on the cessation of an antagonist, is always most marked at the commencement, whereas, in the rigidity of hemiplegia, it is usually weeks or months before it sets in. And if it were cerebellar influx, I should further look for the rigidity in the extensor muscles of the trunk and legs, owing to the more especial relation of the cerebellum to these movements; whereas the very contrary holds, as the rigidity is most marked, and, in a large majority of cases, is confined to the arm and flexors more especially. The rigidity, in fact, seems to affect those muscles most which are most paralysed by destructive lesions of the hemispheres. If it be objected—and this seems to be the main objection—that the remittent or intermittent character of the late rigidity, in its early stages, militates against the idea of its being dependent on a permanent organic lesion, we can find analogous phenomena. The neuralgic pains which are associated with progressive sclerosis of the posterior columns of the spinal cord are not constant, but remit, intermit, or vary under different conditions, which modify the nutrition and activity of the nerve-centres. It seems to me more in accordance with all the facts to attribute, with Charcot, etc., the late rigidity to irritation set up by the process of degeneration of the motor tracts, just as in protopathic lateral sclerosis.

As regards the temperature of the paralysed limbs, in central and cortical disease respectively, there seems to be some uncertainty, and we cannot speak definitely on this point as yet. It is, however, generally stated† that there is less difference in temperature between the two sides when the paralysis depends on cortical than on central disease. It is certainly less marked than in paralysis due to mesencephalic lesions. Experiments have been made on animals, with a view to determine the question; but the results do not seem quite in harmony with each other. Eulenburg and Landois state that vaso-motor paralysis occurs in dogs, in consequence of destruction of the cortical motor centres in this animal, and in this they are supported by Hitzig. Vulpian, however, fails to detect such phenomena. And it would appear, from a preliminary communication by Küssner,‡ that, in rabbits at least, no vaso-motor paralysis occurs from cortical lesions. It may be that the representation of the vaso-motor centres in the hemispheres follows the same laws as the motor centres in different orders of animals, and that the vaso-motor paralysis, at first resulting from cortical lesions, subsides more rapidly than when the lesion is central; and this seems to me highly probable. That vaso-motor should accompany motor paralysis from cortical lesions is, I think, what might be expected, from what we know of the physiology of motor and its correlated vaso-motor innervation; and that such vaso-motor paralysis should subside more rapidly in cases of cortical lesion would, I think, be in harmony with the comparative escape of movements independently organised in lower centres. To the correlated vaso-motor disturbances, I would ascribe the subjective sensations of numbness, tingling, and the like, which so frequently

\* For these various statistics I am indebted to Küssmaul, *Die Störungen der Sprache*, Ziemssen's *Handbuch*, vol. xii, Anhang, 1877.

† *Lancet*, 1873, vol. ii, p. 449.

usher in paralysis or spasm in connection with lesions of the motor centres, rather than look upon them as projected central sensory irritation.

Hemiplegia, complete from the first and permanent, is not, however, the most common type of paralysis depending on lesion of the cortex or subjacent medullary fibres. More frequently, paralysis of cortical origin is fractional or dissociated, or is a succession of dissociated paralyses or monoplegiae. In cortical affections, we frequently find a hemiplegia, at first complete, resolving itself into a monoplegia; or a monoplegia becoming a hemiplegia by progressive advance of the disease to other motor centres. This latter is a significant indication of cortical disease. Paralysis of voluntary motion of the arm and leg; of the arm and face, or this combined with aphasia, if the lesion be in the left hemisphere; or paralysis of the inferior facial region; of the arm alone; or of certain movements of the hand and arm; or of the leg alone; without affection of sensation, and without qualitative or quantitative changes in electrical contractility, or direct impairment of nutrition, may be looked upon as depending on lesions of the cortex or subjacent medullary fibres. Monoplegia is very often associated with monospasm or early rigidity of the paralysed limb, or of the muscles governed by the centres surrounding the lesion. Sometimes the paralysed limb may remain motionless while convulsions occur in the others. Cortical paralysis is frequently erratic and transitory, more especially in connection with superficial meningo-encephalitis; appearing and then vanishing, first on one side and then on the other. According as the lesion is superficial, or deep, and invading the whole depth of the cortex and subjacent medulla, we get transitory paralysis, or a paralysis which remains permanent, and is followed by descending sclerosis and late rigidity.

Whereas early rigidity is of frequent occurrence in cortical disease, it is rare in central cerebral disease; and then particularly, it would seem, when the medullary fasciculi of the fronto-parietal region are irritated—a condition generally found in connection with hæmorrhagic effusions into the lateral ventricles. Consciousness is less frequently lost in cases of sudden cortical lesion than when similar disease occurs in the central ganglia. This is to be accounted for by the special tendency in the latter case to sudden displacement of the cerebro-spinal fluid, and, through this, general disturbance of the cerebral circulation, in the manner indicated by Duret.

As an accessory element in the diagnosis of cortical lesions, may be taken the fact, noticed by Callender\* and others, that cortical lesions are more frequently accompanied by localised pain in the head; and I have frequently observed that, even when pain is not spontaneously complained of, it may be brought out by percussion over the seat of lesion.

While we cannot be quite certain of the position or extent of a cortical lesion causing a sudden and complete hemiplegia, we may take a monoplegia of the leg, or of the arm and leg, as an indication of lesion of the upper extremity of the ascending convolutions close to the longitudinal fissure; brachial monoplegia, as a sign of lesion of the upper part of the ascending frontal convolution, or, if the paralysis affect the hand more particularly, of the ascending parietal convolution; brachio-facial monoplegia as indicating lesion of the mid-fronto-parietal region; while facial and oral monoplegia, or this combined with aphasia, indicates lesion of the lower part of the ascending frontal convolution, where the third frontal unites with it.

## SURGICAL MEMORANDA.

### CATGUT DRAINS.

MR. PLAYFAIR is, I have no doubt, correct in his criticism upon my views as to the physics of capillarity, and I am quite ready to accept his statement; but he will allow me to say that the experiment to which I referred was one likely to lead to the view I took of the subject. More explicitly, the experiment referred to was of the following nature. One end of a skein of catgut, not tied together, and therefore with the separate strands at some distance from one another, was placed in an urine-glass filled to the brim with water. The other end hung over the side of a second glass of the same height. In a little time, the water began to run over; but after about an hour the flow completely and finally ceased. The water in the full glass had sunk about a quarter of an inch. I do not venture to argue the physics of the question; but such are the facts. This experiment was performed in one of the wards of the infirmary, and was watched by several of the students.

## CLAUDE BERNARD:

### A LECTURE

*Delivered to the Senior Class of Physiology at the Physiological Laboratory, New Museums, Cambridge.*

BY MICHAEL FOSTER, M.D., F.R.S.,

Trinity Praelector in Physiology.

GENTLEMEN,—It has long been a heavy burden on my conscience that, while you are receiving your instruction in physiology here, you are told but little of the history of science—that your attention is only rarely and incidentally called to the various steps by which we have reached our present outlook. I fear that such historical statements as do reach you are sadly limited to the controversies of the last decennium. The names you hear quoted are too often those of the authors of the most recent memoirs and of the last new contradiction; and I shall probably be going not far wrong when I say that, were your knowledge limited to what is uttered here, you would be almost justified in supposing that, except for the changes embodied in about the last dozen volumes of Pflüger's *Archiv*, Physiology might have been, like man, created in its present form in the Garden of Eden. This state of things, though undesirable, is, in large measure, unavoidable. Our time is so short, and the body of knowledge we have to traverse so great, that it is absolutely impossible for us to devote an hour's study to the history of our science without foregoing a corresponding quantity of the science itself; and, on the whole, we do well to choose the knowledge itself rather than the story of how we have come into possession of it. The recent death of a great physiologist, Claude Bernard, has, however, determined me to spend the whole of to-day's lecture in pointing out to how large an extent the modern doctrines of physiology have been influenced by his brilliant investigations.

It is not my purpose to dwell upon his personal history; indeed, there is happily but little to tell. Men of science are fortunate when their personal histories are uneventful; they live in their work and not in their lives. And Claude Bernard was in this sense fortunate. All I know of him is that he was born in the sunny South of France, at Saint-Julien, near Villefranche (Rhône), on July 12th, 1813; and that, when nineteen years of age, he came to Paris as an aspirant for literary fame, carrying in his pocket an unaccepted tragedy and a comedy which had enjoyed an obscure provincial success. Arrived in Paris, he was told by a judicious friend (Saint-Marc Girardin) that "poetry was a bad trade, but might be made a profitable amusement." Other lovers of poetry in general, and of their own in particular, have at divers times received the same valuable advice. Bernard was in some respects singular, in that he obeyed that advice to the letter. The transition from dramatic poetry to the dissecting-room is great and startling, but he did not shrink from it; he became a medical student. In 1839, he became *interne des hôpitaux*. So far, he had given no token of his future eminence; but, in 1841, he was made assistant to Magendie, and then it was that he found his calling.

It is impossible to understand Bernard's life unless the character and influence of Magendie be rightly appreciated; and here, again, I fear that, save in the matter of the functions of the roots of spinal nerves, the name of Magendie conveys no particular ideas to your minds; and yet it occupies a most honourable place in the history of physiology. Magendie was born in 1783 and died in 1855, so that the lives of himself and his pupil Bernard extend over just about a century. During that century, the progress of physiology has been immense; and if I were to ask any of you what has been the distinguishing token of the physiology of this nineteenth century, you would answer "Experimental investigation, the application of chemical and physical knowledge and methods to the solution of biological problems." Now, Magendie was *par excellence* an experimentalist; his whole life was a prolonged effort to unravel physiological phenomena, by the help of chemical and physical methods, applied in a direct experimental manner. He is, in a certain sense, the father of modern experimental physiology. You must remember that, in his time, Germany did not possess the institutions and appliances of which she is now justly proud, and which

\* Paul Bert, Preface to *La Science Expérimentale*, par Claude Bernard. Paris, 1878.

we equally justly envy her. In the early part of this century, there were no physiological laboratories at Leipzig or Berlin, or elsewhere. Experimental inquiry in Germany was occasional and slight; indeed, hardly more was being done then in that country than in our own. Magendie stood almost alone as a professed and systematic experimentalist; and, willing as we English always should be to acknowledge, in the fullest possible manner, the benefits which physiology has received from Germany during the last fifty years, we must at the same time not forget that France led the way. That Magendie has not left more mark than he has on the science which he cultivated, is due to two reasons. In the first place, he was to a certain extent before his time. His tools were chemistry and physics; and these had, in his time, not as yet acquired the excellence and precision necessary for his purpose. He tried to do fine work with rough instruments, and, as a matter of course, in many cases failed. Were he living now, instead of fifty years ago, with all the appliances at his command which we have at ours, his name would be in yours and everybody's mouth. In the second place, it must be admitted that, with all his brilliant talents, Magendie's mind was limited. He was essentially *doctrinaire*. Impressed with the physical and chemical aspects of vital phenomena, he did not realise the profound complexity of the molecular changes of living matter. He did not grasp the view, that the apparently simple phenomena of living beings, even if at bottom molecular phenomena, and as such subject to physical laws and capable of physical interpretation, are so transformed that they need to be studied from a stand-point of their own, as if they were phenomena *sui generis*. His sharp sceptical intellect saw through the hollowness and insufficiency of the vitalistic doctrines current in his day, but his mind was not broad enough to recognise that they were the distorted shadows of a real substance. In one word, clear and able as he was, Magendie was without genius. But what was lacking in him abounded in the young spoiled dramatic poet, who came to him first as his pupil, remained as his assistant, and finally succeeded to his chair. And this reminds me that I must return from this digression.

While assistant to Magendie, Bernard published, in 1843, his first memoir, *Recherches Anatomiques et Physiologiques sur la Corde du Tympan*, which was speedily followed by an inaugural thesis, delivered upon his becoming doctor of medicine, the title of which was *De Sac Gastric et de son Rôle dans la Nutrition*. It is suggestive that his two initial pieces of work should be in the two lines along which he was afterwards destined to labour so fruitfully. In 1854, he was appointed Professor of General Physiology in the Faculty of Sciences, a chair established on purpose that he might fill it; and, in 1855, upon the death of Magendie, he was called to the Chair of Medicine, *i. e.*, of Experimental Physiology, in the Collège de France, so long held by his master. Here for many years he laboured, receiving in due time various academic and other honours. In 1868, he quitted the Faculty of Sciences to take the place, formerly held by Flourens, of Professor of General Physiology at the Muséum d'Histoire Naturelle, succeeding Flourens also at the Académie Française. In 1869, he entered the Senate. In 1876, he received the highest scientific honour which England can bestow: the Copley Medal. Having, in the course of a life not so long, won renown in the eyes of all who love science; having come to be a prophet not without honour in his own country; having passed his days loved by all who had the happiness to know him in the flesh, he was taken with illness, in the laboratory, in the midst of his work, and died, from renal disease, on the 10th of February that has just gone by.

It is not my purpose to-day to sit, as your teacher, in judgment on the scientific character of Claude Bernard. He had his faults, and these not inconsiderable ones. I said just now that he had genius; he had also some of the failings which are proverbially said to hang on genius. When you read his writings, you will not fail to be struck with a certain rashness and want of carefulness in his statements, and indeed in his deductions. Thus, in his lectures you will come upon a statement of this kind, that the stimulation of the vagus produces arrest of the heart's beat either in systole or in diastole, according as whether the application of the stimulation takes place during systole or during diastole. Now you have all known, from your physiological infancy upwards, that this is simply an error, that cardiac arrest from stimulation of the vagus is always a diastolic arrest. And in going over Bernard's works, I might point out very many errors of as grave or even graver nature. So much so is this the case, that his books are undesirable books to put in the hands of a beginner or amateur. They always need to be read with the critical faculty alert; otherwise, they are apt to mislead, and, indeed, to do harm; for, as you well know, a writer's errors are always more readily laid hold of and obstinately clung to than his truths; and I have known hangers-on of physiology build up specious quasi-physiological doctrines on a foundation supplied

by some enticing but wholly erroneous observation of Bernard. In a smaller man, these faults would be serious matters; but in Bernard's case, they fade away like slight mists before the rays of his grand discoveries. Even in his lifetime, we were content to forget them; let it be much more so after his death. Happily, the lives of men of science are unlike those of politicians, inasmuch as the good they do lives after them; it is the evil which is interred with their bones. So let it be with Claude Bernard. We have no need to dwell on his shortcomings when we remember that it was his good fortune, amid a large quantity of slighter but still useful work, to make at least the two, we may perhaps even say the three or four, most brilliant physiological discoveries of the half century during which he lived. It is to these to which I wish to call your attention for a little while. My object to-day, indeed, is not to draw up a valuation of Bernard himself, but to point out to you the bearings of his labours.

Let me first turn to the earliest and to the least important of his capital investigations; to his work on the pancreas. Bernard's investigations into the function of the pancreas were made in the year 1846, but were not published till two years afterwards. Let me briefly point out what was the state of our knowledge previous to the appearance of his memoir.

If you read, as I trust some of you sooner or later will do, the *Elementa Physiologie* of the great Haller, you will find that Father of physiology, after a long and laborious discussion of the views of others, concluding that the great use of the pancreatic secretion is to dilute the bile and to temper the acerbity of that fluid in order that it may mingle more freely with the mass of the food along the intestine, and so promote the digestion of the rest of the food. "Hence," says he, "the pancreas of the crocodile is so very large, for the bile of that creature is, indeed, most acrid."\*

If you turn to the first edition of Carpenter's *Human Physiology*, published eighty years later—1842—and which is well worthy your study as an admirable exposition of what were the advanced doctrines of physiology forty years ago, you will read on page 359, as a summary of what was known concerning the action of the pancreatic juice, the following meagre sentence. "The chyme is mingled in the duodenum with the biliary and pancreatic secretions, which effect an immediate alteration both in its sensible and chemical properties."

In point of exact knowledge, this is hardly an advance upon the teaching of Haller. In one respect, indeed, the modern doctrines had gone astray. The older writers, filled as they were with great reverence for the bile, admitted fully the importance of the intestinal digestion; the later inquirers, misled by the striking observations of Beaumont and the discovery of artificial peptic digestion, had gradually been leaning more and more to the view that stomachal digestion was all in all. You know that, in the elementary lectures, I am in the habit of insisting that peptic digestion is at the best a preparatory process, and that the great conversion of food takes place along the length of the intestine. This, the now current doctrine of digestion, dates from the publication of Bernard's memoir. It is true that Valentini† suspected, from the prominence of the pancreas in herbivora, that its secretion converted starch into sugar, and indeed Bouchardat and Sandras‡ had shown this to be the case in fowls. Leuret and Lassaigue also had come to a similar conclusion. But this most important fact cannot be said to have been fairly established, until Bernard proved that it was a constant property of pancreatic juice in all animals and under all circumstances. It is also true that Eberle had previously suggested that the pancreatic juice might have a specific effect on the fats of food; but to Bernard belongs the credit of having pointed out the emulsifying power of that fluid, and of having discovered its peculiar action in splitting up neutral fats. In this matter, as in many other points, Bernard gave way to exaggeration. He insisted that the pancreas, and the pancreas alone, was the agent for the digestion of fat, and his exaggerated views were very naturally contested by Bidder, Schmidt, and others. You know, however, that in this place, we teach that Bernard was so far at least in the right, that the pancreas must be considered as the chief digester of fats, though probably largely assisted by the bile. Lastly, it is true that Tiedemann and Gmelin§ had suggested a connection between the pancreatic juice and proteid food; but their view was a fantastic and erroneous one. They thought that "the casein (alkali-albumin) of the pancreatic secretion, since it contains a large proportion of nitrogen, yields a portion of this element to the different ingredients of the alimentary substances which contain an insufficiency of nitrogen, and thus converts them into albumin, while reducing itself to their standard". Very different from this view is

\* *Elementa Physiol.*, vol. vi, p. 453 (1764).

† Lehmann, *Physiol. Chem.*, Band ii, p. 91.

‡ *Compt. Rend.*, tome xx, 1825.

§ Müller's *Physiology* (Baly's translation), vol. i, p. 600, 184.

the conclusion at which Bernard arrived, that the pancreatic juice dissolves and digests the proteid matters of food, both those which have not been dissolved by the gastric juice and those which, having been thus dissolved, have been reprecipitated by the bile. In fact, before Bernard's memoir, the state of things was this. The action of pancreatic juice on starch was just beginning to be recognised, its action on fats was only just hinted at, and its action on proteids, so to speak, unknown. Bernard clearly proved the existence and pointed out the importance of all these three actions, and thereby restored intestinal digestion to its proper position. I need hardly point out to you how, by the subsequent labours of Corvisart, and especially of Kühne, our knowledge of the proteolytic action of pancreatic juice has made vast strides, and what a flood of light has thereby been thrown not on digestion (and let us hope on indigestion also) only, but on the metabolism of the whole body. The first steps of this inquiry, the ultimate worth of which it is almost impossible to exaggerate, we owe to Claude Bernard.

Far more important, however, than this pancreatic work was the next research, with the results of which Bernard startled the physiological world. I have already spoken of two at least of Bernard's discoveries as being the most important of the mid-century; one of these was his discovery of glycogen and of the glycogenic function of the liver, made known to the world in 1849.\*

This discovery naturally starts from the knowledge of the presence of sugar in the blood, which, by a curious coincidence, we owe to Magendie. I need not pass in review before you the details of this great step. Suffice it to say, that the whole credit of it belonged to Bernard. Both the truth and the value of it were of course denied by some, and a long controversy, now happily forgotten, arose about it; but in the end Bernard, supported especially by Lehmann,† came out triumphant. He not only proved the glycogenic function of the liver, but was the first to extract glycogen, though this was independently, at a subsequent date, discovered by Hensen.‡ And to Bernard alone must be attributed the discovery of the diabetic puncture.§ But these matters are household words in all physiological schools; the names Bernard and glycogen are, and always will be, inseparable. You all know, too, how subsequent researches have somewhat modified the views first put forward by Bernard; at the present moment we do not, as he was at least inclined to do, regard proteid matter as the chief, much less as the only, source of glycogen. I should, however, like to spend a few moments in pointing out to you the bearings of this discovery.

Not so very long before Bernard commenced his work, physiologists almost unanimously subscribed to the dogma of Dumas, that "the plant creates, the animal only destroys". This doctrine has been in reality upset by Liebig's proof that fat was actually formed, and not merely accumulated, in the animal body; but it was a doctrine of great tenacity, capable of living in the face of obvious disproof. The discovery of glycogen may be said to have given it its *coup de grâce*. After that it could no longer hold up its head; and to you who, from the beginning of your biological studies, are indoctrinated with the view that the bodies of the complex animal and the complex plant are mere instances of the differentiation along two diverging lines of a common protoplasm, it may perchance seem strange that such a view should ever have been held. It was held though, and that most strongly; and the fact that it now belongs to past history we owe, next to Liebig, to Bernard's discovery of glycogen.

There is, moreover, a second aspect, in which this work of Bernard's acquires even greater importance. There was a time, not so far distant, when the animal body was regarded as merely a bundle, somewhat loosely tied together, of machines called organs, each of which had its special work or function; and the whole work of physiological inquiry was tacitly held to be limited to the finding out what was the function of this or that organ. Hence it came to pass, that when a "function" had been allotted to an organ, there seemed little more to be done. When, for instance, it was stated that the function of the liver was to secrete bile, it was felt that physiological inquiry had done its duty as regards that mass of tissue, and that there was nothing more to be done. Into such a view as this, the discovery of glycogen fell like a bomb-shell. That one organ should have two functions, and those so utterly different, seemed scarcely less than a scandal. And when Bernard went on to show that this same glycogenic "function" was shared by the placenta, by muscular fibres, by epithelial struc-

tures, and indeed might, under appropriate circumstances, be taken on by almost any tissue, the old mechanical theory of organ and function fell to the ground. I do not say that its downfall was not being prepared in many ways by other researches; it received a great shock when Bichat wrote on *The Tissues*; it, while retaining the old phrases, had for some years become more and more unreal; but the final death-blow was dealt by Claude Bernard. It is, I venture to think, not too much to say that if one sign of modern physiology be more hopeful than another, it is the tendency of present inquiries to attack the phenomena of living beings as the co-ordinated results of the concurrent and conflicting properties of variously differentiated living matter, and not as the mechanical outcome of a group of organic machines.

I must now pass on to Bernard's second great discovery, that which, in reality, forms the basis of our present doctrines of vaso-motor action. It is possible, that when I use the word vaso-motor, some of you may be reminded of that gourmand who grew weary of partridges when served every day for dinner. And, indeed, if we were to mark out the history of physiology into epochs, the present might fairly be called the vaso-motor epoch. You think you hear in this place a great deal of vaso-motor nerves and vaso-motor actions. I can assure you that I, for your sake, have to read a still great deal more. Hardly a number of a physiological journal is laid upon my table which does not contain what might be called a vaso-motor memoir. This being so, am I not right in speaking of that initial observation of Bernard's upon which the whole of the modern vaso-motor doctrines are based as an event of capital importance? It was in 1851 that Bernard first observed that dilation of the blood-vessels of the head and neck followed upon the division of the cervical sympathetic. From that simple observation has sprung all the vaso-motor learning which is now poured so plentifully into your minds.

[To be continued.]

## REMARKS

ON

### THE RECENT OCCURRENCE OF AGUE IN YOUNG CHILDREN IN LONDON: ILLUSTRATED BY FIVE CASES.

By W. B. CHEADLE, M.D., F.R.C.P.,

Physician to the Hospital for Sick Children, Great Ormond Street; Senior Assistant Physician to St. Mary's Hospital; etc.

THE heavy rainfall of the last few seasons appears to have revived a disease which had been almost stamped out by the progress of modern improvement. Ague, with all its striking features fully developed in the acute and early stage of the primary disease, is rarely seen in London now-a-days. Every now and then a well marked case is admitted into the Seamen's Hospital at Greenwich; but in the General Hospitals of London proper the primary forms of intermittent fever are extremely infrequent. Relapses and the irregular recurrence of the later stages are indeed met with, but an initial attack rarely. Similarly, in private practice, a genuine unmitigated attack of ague in full blow, at any rate in the regular form of its earlier stages, is, I imagine, hardly ever encountered in London. Children are said to be less liable to the disease than adults. I have met with cases occasionally, at long intervals, in my practice at Great Ormond Street, during the last ten years; but none so severe, or presenting such striking features, as two out of the five which have come under my observation during the last twelve months.

CASE 1. *Severe attack of Tertian Ague in a Child aged two years and nine months, developed five months after residence in an Ague District: Appearance of Rash simulating that of Scarlatina: Immediate Cure by Quinine.*—On February 28th last year, I was asked by one of my colleagues to see his child, a little girl two years and nine months old, who was suffering, as was supposed, from scarlatina. The patient was also seen by Dr. Mahomed and Dr. Broadbent, who kindly gave their assistance in the case, and were as much interested in it as myself. When I first saw the child, about four o'clock, it was in a state of high fever, with a pulse of 116 and temperature of 104 deg., and covered with bright red suffusion of the skin, closely resembling the rash of scarlatina. The throat, however, was not congested, and the tongue, although rather white, was not reddened or strawberry-like. The child was teething, and the gum over one of the double teeth was swollen and a little tender, but did not appear to give any pain or distress. I learnt that the illness had commenced two days before, about 9 A.M., with a sharp shivering fit; a hot-bath was given, after which a bright

scarlet rash appeared all over the body, accompanied by dry burning skin, and a temperature of 102 deg. and pulse of 110. This condition continued about three hours, when the skin became freely perspiring and the febrile symptoms subsided; the rash also faded away. A dose of castor-oil was given, and the next day the child was playing about as usual, apparently well. On the succeeding day, however—*i. e.*, about seven o'clock in the morning of the day on which I was called in—the same series of symptoms recurred, *viz.*, shivering, followed by high fever, with a temperature of 104 deg. and pulse 116, and the appearance of a bright scarlet rash all over the body. So like was this to the eruption of scarlatina, that the case had been assumed to be certainly one of scarlet fever, and it was proposed to transfer the child at once to the Fever Hospital. The scarlet, punctate, universal rash, without doubt, looked uncommonly like that of scarlet fever; but in view of the absence of sore throat, the condition of the tongue, the anomalous onset, the remissions of the fever, and the eruption, I could not endorse the conclusion as positive, and it was decided to await further developments. Two grains of calomel were given, and the next day the symptoms had subsided. The rash had disappeared, the pulse and temperature were normal, the tongue nearly clean, and, except that the child appeared a little weak and languid, she was herself again. No more medicine was given, and the febrile seizure, although the subject of argument and conjecture, remained to a great extent unexplained.

The improvement in the patient's state was, however, only temporary; for, at 3.30 the following morning, the rigors came on afresh, followed by burning fever and delirium. At nine o'clock, Dr. Broadbent, Dr. Mahomed, and myself saw the child together. We found it with a dry harsh burning skin, a white-coated and extremely dry tongue, a temperature of 106 deg. and pulse 130. There was no distinct rash visible, but perceptible although slight hyperæmia of the skin. The attacks were now seen to be distinctly intermittent, having occurred three times on alternate days, although not with absolute regularity as to the hour, commencing in each succeeding instance a few hours earlier in the morning. The question then arose: Whether the case was one of genuine ague, or a less defined febrile condition dependent on some cause yet obscure? In view of the periodic character of the attacks, half a grain of quinine was ordered to be given every four hours, and two grains at bedtime in addition. The swollen gum was also lanced. The next day, the child was again apparently well, but this was the day of immunity. The quinine was continued; and the following night, on which the seizure would have come in regular course, passed without any other symptom than slight feverishness and restlessness; there was just enough, as the nurse said, to make her feel sure that an attack was coming on. There was, however, no further development, and the slight fever and irritability passed off by morning. On more careful inquiry, we now ascertained that, in the previous August and September, this child and another had been staying in Essex, in a place where ague occurred occasionally from time to time. During their stay there, however, which extended over two months, the children had enjoyed perfect health. These facts, together with the regularly intermittent character of the attacks, and their sudden cessation under quinine, were decisive. The treatment was continued, and the attacks did not recur. A fortnight later, the diagnosis was confirmed by the occurrence of the second case.

**CASE II. Tertian Ague in a Child aged one year and nine months, brother of the patient in the preceding case, developed five months after exposure to malarial poison: Cure by Quinine.**—This child had been the companion of the preceding patient in the visit to Essex; and, about a fortnight after the elder child was attacked, the second was seized with exactly the same symptoms, *viz.*, a shivering fit, followed by burning fever, ending in profuse sweating, with a temperature of 105 deg. and pulse 120. These attacks recurred regularly every other day, for five times, and were then cured at once by quinine. In this instance, no rash was observed. Two months later, the first child had a relapse: a single fit of ague, exactly similar to those of the first series. Quinine was given as before, and there was no recurrence. The spleen was not found to be enlarged in either case.

In addition to these two typical cases of tertian ague, I have, during the last twelve months, met with three other examples of intermittent fever in children. These were less regular in form and of less pronounced features than the preceding. With regard to two of them, there cannot, however, I think, be much doubt. The third is perhaps of more questionable identity. I give the particulars of them very briefly.

**CASE III. Quotidian Ague, in a Child aged four years; Enlargement of the Spleen: Cure by Quinine.**—Louise S., aged four years, living in Gray's Inn Road, was admitted into the Hospital in Great Ormond Street, on April 27th, 1877. The family had lived at Sheerness for two years, and only came to London one month ago. A year ago,

while at Sheerness, the father had ague; and, seven days after their arrival in London, this child became fretful, languid, and feverish, followed by a well marked attack of shivering a few days later. The fit recurred daily, lasting from half an hour to an hour and a half, and was followed by a hot stage of some thirty minutes' duration, which ended in sweating. The attacks were ushered in and succeeded by frontal headache; they came on at first about ten o'clock in the morning, but had been gradually getting later, and now occurred about two o'clock in the afternoon. The child had taken quinine from the outset, the mother giving it "a pennyworth" a day. Another child had similar attacks, but every other day only. On examination, the spleen was found enlarged, hard, extending three fingers' breadths below the ribs. The tongue was slightly coated with white fur. The urine was free from albumen. The temperature was subnormal, 96 deg. Two days after admission, the temperature rose to 100 deg., and there was frontal headache, but no rigors or hot stage. The headache recurred once or twice, but the temperature did not again rise. No drugs were given. No further symptoms of ague were developed, and the patient was discharged on May 18th. The spleen had then returned to its normal dimensions.

**CASE IV.—Intermittent Attacks of Shivering and Fever in a Child aged eight years: History of ague: Enlargement of the spleen: Cessation of the attacks without medicinal treatment.**—Minnie P., aged 8, was admitted under my care at the Hospital for Sick Children November 9th, 1877. She was said to suffer from attacks of shivering and sense of extreme chilliness; this cold stage being ushered in by headache, and lasting two or three hours; it was followed by burning heat, ending in perspiration. The last stage was often accompanied by vomiting, and the attack altogether was usually of four or five hours' duration, the febrile stage preceding the perspiration generally lasting about an hour. The attacks have become less frequent and less severe than formerly, and now occur about once a month only. The exact frequency of recurrence at an earlier period could not be ascertained. In June, the child received a blow on the elbow, followed by five abscesses up the arm, which had only just got better at the time of her admission. While the abscesses were forming, the abdomen was said to have swelled to twice its natural size, accompanied by diarrhoea, which lasted three or four months, and indeed still exists intermittently.

On examination, the child was seen to be fairly well nourished, of an unusually mottled bronzed complexion, more than consonant with the darkness of her hair. The tongue was clean, pulse and temperature normal, appetite good, urine free from albumen. The abdomen was full, but resonant; it measured  $23\frac{3}{4}$  inches at the umbilicus. The spleen was decidedly enlarged, being felt nearly three inches below the margin of the ribs. Her mother stated that she and her family had lived at Hendon for the last twelve years and a half; that she first contracted ague, when living in a damp locality there, in a house built on the earth without excavation beneath, some ten years ago. Her first child contracted it at the same time, and the second, with which she was then pregnant, had it when born. The present patient is her fourth child; it was born at seven months, the mother suffering from ague-fits while carrying it; and she affirms that the child shook in the womb, and had ague directly it was born, from which it nearly died. She further affirms that there have been many cases of ague in the neighbourhood. Two of the other children and the mother were examined, but no enlargement of the spleen could be found.

The patient was kept without medicine for a week; no symptoms of ague appeared. Two grains of quinine were then given three times a day, and the child continuing free, she was sent to Highgate, the spleen being still as large as on admission. The circumstantial history of a succession of attacks of ague in other members of the family, the prevalence of the disease in the district, together with the intermittent character of the seizures and the existence of enlargement of the spleen, seemed to be conclusive evidence as to the nature of the affection in this case. Further inquiry into the statements of the mother, with regard to the prevalence of ague in the neighbourhood, has not led to their confirmation. My friend Dr. Andrew of Hendon informs me that he has met with no instance of the kind during the last five years; and that, although he attended this child for some ailment last year, he had never heard that she or any of the family had had ague previous to my inquiry. The mother, however, adheres to the account she gave me, and the enlargement of the spleen is, of course, strongly corroborative evidence.

**CASE V.—Intermittent Attacks of Shivering and Fever in a Child aged five years, ushered in by a rash simulating that of Scarlet Fever: No enlargement of the spleen: Cessation of the fits under treatment by quinine.**—Mary Ann S., aged 5, living in Drury Lane, was admitted into the Hospital for Sick Children, Great Ormond Street, November 16th, 1877. The mother stated that the child had always enjoyed good

health until two years ago, when she complained of a feeling of heaviness and pain over the left eyebrow. This was followed by ptosis and external strabismus of that eye, which persisted for some months. About six months ago, she was seized with intense pain in the right heel and ankle, accompanied by numbness of the thigh and in the toes. Ten weeks ago, she had what was supposed to be scarlet fever, the attack commencing with a shivering-fit, which lasted from half-an-hour to an hour; this was followed by a burning heat and red rash all over, and terminated in a fit of profuse sweating. There was also severe pain across the loins, high-coloured urine, and great thirst afterwards. Similar attacks recurred about once a week, latterly only once a fortnight; the last was five days ago. There was no history or sign of congenital syphilis. No similar attacks had occurred in any others of the family, or amongst the people in the neighbourhood.

On examination, the child was seen to be anæmic, and appeared feeble, depressed, and fretful. The tongue was much furred, and rather dry. There was no albumen in the urine; the temperature was normal. Physical examination of the chest and abdomen disclosed nothing abnormal. The spleen could only just be felt on deep inspiration. On the day of admission, the child had a shivering-fit, and the nurse who saw it described her as looking cold, and that her legs trembled; the attack lasted about ten minutes. Two grains of quinine were given with ten minims of liquid extract of bark three times a day, and, there being no return of the seizures, she was discharged at the end of three weeks convalescent.

REMARKS.—The first notable point in these cases is the occurrence of the scarlet rash observed in the first and in the fifth. In the first, the eruption was so distinct, and apparently so typical, that it was at once assumed without question to be the eruption of scarlatina; and undoubtedly the occurrence of this rash, together with high fever, greatly obscured the diagnosis at the outset. In the fifth case, the original attack was set down as scarlatinal, and its possible malarial character only transpired on cross-examination afterwards. So far as I can ascertain, although there is often some flushing of the face, such general scarlet eruption does not occur in adults. I have never previously observed it in the intermittent fevers of children, nor can I discover any instance of its occurrence on record. Its development is, however, entirely consistent with what we see in children in analogous conditions. In them, the sharp pyrexia of various acute disorders is frequently attended at the outset with a cutaneous hyperæmia so well marked and so general as to be often mistaken even by experienced practitioners for the eruption of scarlatina. I have seen it in empyema; it is not uncommon in the traumatic fever which follows operations or injuries; and it is met with in various other febrile disorders. This pyrexial erythema is usually partial—not, indeed, in well-defined patches; but it is only distinct on certain parts of the body, such as the neck, chest, and abdomen, for example; and fades away insensibly into the surrounding skin. I have never seen it so bright and deep in colour, nor so uniform, as in this instance; and the pathological conditions in ague would appear to be favourable to the abnormal development of cutaneous hyperæmia. There is marked vascular disturbance, and the contraction of the cutaneous vessels during the cold fit is followed by excessive relaxation during the hot stage which succeeds it. Hyperæmia of the superficial vessels so extreme as to constitute a distinct scarlet rash appears, however, to be the exception. It was observed only in the first case, which was the most severe; and in the fifth.

Another point of much interest is the long period of latency which intervened between the exposure to the malarious poison and the first manifestation of the disease. Such lengthened incubation is by no means unknown. Attacks of remittent fever contracted in a tropical climate sometimes make their first appearance after the return of the patient to England; and similarly ague occasionally appears for the first time in a person resident in some dry healthy locality, but who visited a marshy district months before, where the disease was undoubtedly contracted. Yet this long term of quiescence of the poison after its reception, and the apparent extreme variability of its duration, are most remarkable, for they are far beyond the limits met with in any other disorder dependent upon the entry of a malarial poison into the body, except only that most fearful and strange disease of all—hydrophobia. In it, not months merely, but years even, may elapse between the primary infection and the development of symptoms. Ague stands in this respect between it and the contagious fevers.

I mentioned at the outset that ague had been unusually rife from the autumn of 1876 until the present time. In addition to the four cases here recorded, there has been, I believe, one other in the Children's Hospital under the care of one of my colleagues. For several years previously, I have not met with a single instance. Dr. Ralfe, Physician to the *Dreadnought* Hospital at Greenwich, informs me that it has been

exceptionally prevalent amongst seamen and the boatmen of the Lower Thames. He states, moreover, that not only have intermittent fevers of irregular character, and relapses of ague caught elsewhere, been much more numerous than common, but that cases of primary ague contracted on the Thames, which were formerly rarely seen, have of late become of comparatively common occurrence. Thus the total number of cases of ague admitted into the *Dreadnought* Hospital during the year ending October 1876 was thirty-nine; while during the succeeding twelve months ending October 1877 the number admitted under Dr. Ralfe's care alone was thirty-seven. There would probably be an equal number under the other physician, Dr. Leach; so that the total cases of ague have probably nearly doubled during the last year. Amongst the thirty-seven cases under the care of Dr. Ralfe, there were five of primary attack contracted on the Thames. The explanation of this reappearance of ague seems to lie in the excessive rainfall. The marshy lands artificially drained were deprived of their power of producing the paludal poison; the constant rains of the last two autumns have restored the lands to their former marshy condition, and malaria has temporarily developed again as in the old pre-drainage era.

## THYROTOMY FOR THE REMOVAL OF GROWTHS IN THE LARYNX.

By W. PUGIN THORNTON,

Surgeon to the St. Marylebone General Dispensary.

I SHOULD be glad to have an opportunity of making some remarks on the paper relating to a case of thyrotomy for the removal of growths in the larynx, which was brought forward by Professor Lister and Dr. Burney Yeo at the meeting of the Clinical Society on February 22nd, and was reported in the *BRITISH MEDICAL JOURNAL* of the following week.

There was a point of considerable surgical interest in the treatment of Mr. Lister's case, on which no discussion took place. I refer to the method of drawing together the split halves of the thyroid cartilage by passing a silver wire not only into their substance, but completely through their walls. It was on the second or third day after the operation, on seeing the man in King's College Hospital, that I first learnt the value of such a measure, Mr. Lister very kindly explaining the case to me at the bedside of the patient, and subsequently ordering him to show how good a voice he had. I confess it was with horror that I witnessed the man's attempts to speak; for it has always been my custom, in cases of thyrotomy, to close the thyroid cartilage by passing the sutures only into the substance, taking special care that the wire should not enter the cavity of the larynx. In the twenty-seventh volume of the *Transactions* of the Pathological Society, I have related the appearance of the larynx taken from a boy three years and a quarter after thyrotomy. With this patient, aged 2½ years, owing to his constant fits of passionate crying, the divided portions of the cartilage could not be kept closely together, although the sutures were on one occasion reapplied; and, after the child's death (of general marasmus following whooping-cough, which had attacked other members of the family), they were found united by fibrous tissue, so that there was free movement between them. Doubtless, had I used a suture in Mr. Lister's manner, I should have obtained a cartilaginous union.

Mr. Lennox Browne, speaking in favour of thyrotomy, mentioned three accidents which might occur in attempts to remove laryngeal growths through the mouth, and which he had, he said, personally observed. They were as follows: 1. Spasm of the larynx, resulting from the introduction of instruments, and requiring immediate tracheotomy; 2. Removal of normal tissue, leading to ulceration; 3. Injury to the laryngeal cartilages, especially the arytenoid, resulting in paralysis, caries, and death of the patient. Mr. Browne might have added a fourth consequence which will occur in the removal of growths by forceps, if a portion of the growth is left behind—namely, acute inflammation in the larynx—and especially if the residue is large and happens to become bruised by the instrument. This *contretemps* may necessitate tracheotomy very shortly after the operation.

The three accidents doubtless may occur in the practice of any one who uses the laryngoscope; but I feel confident that the greater the skill of the operator the less likelihood there is of their occurring, and therefore the value of the operation should be estimated by the degree of excellence and consequent ratio of result which we know may be attained. I can but remember the high degree of dexterity which I was accustomed to see displayed in the removal of laryngeal growths by forceps, and which was but rarely, in my recollection, followed by any serious conditions—certainly not in a degree sufficient to warrant

the idea that those practising in throat-diseases should think otherwise than of persevering in the carrying out of the intralaryngeal operation, so that in time the highest degree of manipulative skill may be reached which is attainable. It may be that many have not the opportunity of such constant practice in removing laryngeal neoplasms, as would be necessary to perfect themselves in the operation. I would suggest to those who feel the want of practice through the scarcity of laryngeal growths, that they can materially add to their dexterity by accustoming themselves to use a blunt-pointed right-angled probe in the larynx, touching any point previously decided upon.

The removal of growths by the mouth is necessitated in many cases for which thyrotomy would not be permissible, but in which entire relief may be given to the patient by the intralaryngeal plan of operation. Looking to the opinion of some of the best known laryngoscopists abroad, we find Dr. Fauvel of Paris, in his recent work on *Throat Diseases* (page 177), strongly supporting the removal of growths by the mouth; and Professor Bruns of Tübingen, in his work on all cases on record to the end of 1877 of the extirpation of laryngeal growths by the intralaryngeal and extralaryngeal methods, and which was referred to at the meeting by Dr. Semon, shows how great a preference ought to be given to the former operation. Neither do the statistics of Professor Bruns support the statement of Mr. Browne, in which he says, when comparing the two plans of operation, "there was a much greater tendency", after removal of laryngeal neoplasms *per vias naturales*, "to recurrence than was generally supposed; and the recovery of the voice was by no means so complete as was generally thought to be the case by those who had not had an opportunity of personally witnessing the results"; for Dr. Bruns points out that, in twenty-one out of thirty-nine cases of thyrotomy for benign growths, there was a recurrence of the neoplasms; whilst, on the other hand, out of ninety cases of the intralaryngeal operation there were thirty recurrences: again, out of thirty-nine cases favourable for thyrotomy, in only eighteen was the voice restored, whilst in the remainder it was completely lost or very slightly improved by the operation; but by the removal of benign growths by the intralaryngeal method, a very general success was attained.

If I remember rightly, when, by the invitation of Dr. Yeo, I examined his patient's larynx at the Brompton Hospital, I noticed that some portion of the tissues on the right side had been left. Whether they belonged to the ventricular band I could not say; but, this being the case, there would be some clue to the wonderful condition of the man's voice. The interior of his larynx has certainly a most striking appearance; and, if seeing were the only justification for believing, then in that man's throat there would be undeniable clinical evidence of their entire removal, supposing there was no cause to think the vocal cords had not been *in situ* before the operation. This complete enucleation of the intrinsic parts of the larynx should not, in my opinion, be resorted to on the first occasion when thyrotomy is required, unless very urgently demanded; but the opportunity should be given, as in the case of Mr. Lister's patient, for a permanent and complete restoration to an unimpeded respiration and recovery of voice, by simple evulsion of the growths, which result, it has been shown in the annals of thyrotomy, may, though very rarely, be expected. The plan of clearing out the whole of the internal laryngeal structures, which has proved so remarkably successful, may in future, doubtless, often save extirpation of the larynx.

## CLINICAL MEMORANDA.

### CLINICAL REMARKS ON MR. JOHN DUNCAN'S CASE OF EMPYEMA.

OF the many points of great interest and importance touched upon by Mr. Duncan, in his valuable clinical observations on the case which appeared in the *BRITISH MEDICAL JOURNAL* of April 6th, page 476, I desire to draw attention particularly to two, viz.: the unlooked-for failure of the steam spray-producer, and the later management of cases of empyema treated antiseptically.

The failure of the steam spray is, I believe, of not unfrequent occurrence; and an operator may proceed quite happily for a long time before he discovers that pure steam alone is issuing from his spray-apparatus. Again, the steam-jet may suddenly stop without giving him any warning. A properly fitted hand-ball spray-producer is not open to these objections. Dry air, instead of steam, being used to atomise the lotion, any arrest of the spray is at once detected, and, so long as it is in action, it must be of the right quality. Due warning is given to the operator if, for any reason, the spray have to be intermitted.

A somewhat remarkable case of empyema came under my observation a few months ago, which suggested what may, I think, prove an useful modification of the antiseptic treatment. The case was one of secondary empyema, inactive, and of some months' duration.\* After two or three subaqueous tapplings, the pleura was thoroughly evacuated by incision, under the spray, and the usual antiseptic dressings were applied. On the second day, the dressings were renewed; and it was reported by the surgeon that, on withdrawing the tube, only a small quantity of serous fluid escaped. At my next visit, two or three days later, I found that the tube had slipped under the dressings, and, owing to a little delay in the arrival of a new tube that had been ordered, the wound closed. The temperature continuing normal, however, and the fluid that came away on the first removal of dressings having been serous, I determined to let the wound heal and to watch the result. And the result has proved most satisfactory: there has been no reaccumulation, and the free air and what fluid remained have been absorbed, vocal fremitus being now distinct all over the side.

It seems to me, therefore, well worthy of consideration whether, in many cases of empyema, after thoroughly evacuating the fluid antiseptically, and if it be found, at the second or third dressings, that but little fluid have collected, and that little be serous rather than purulent, it would not be better to remove the drainage-tube and allow the wound to heal. By this means, we should save the strength of the patient, lessen the opportunities for accidental admission of foul air to the pleura, and favour the more speedy expansion of the lung, by preventing that periodical collapse which must occur each time the wound is dressed and fresh air admitted. Experience alone can decide as to the value of this method, which has been suggested to me by a happy accident in one case. In cases in which our expectations were disappointed, there would be no difficulty or danger in repeating the operation.

R. DOUGLAS POWELL, M.D., F.R.C.P.,

Physician to the Brompton Hospital for Consumption, etc.

## ACTION OF CELERY ON URINE.

THE following peculiar case happened to one of my patients lately. I should like to hear if any of my brother practitioners have ever had a similar experience.

Mrs. M. sent for me at 11 A.M. She had tried to void urine several times during the night and morning, but could not. She was not subject to this "sort of thing". I drew off a pint and a half of hysterical-looking urine, and left. She sent for me again urgently at about 3 P.M. on the same day, complaining of pain, and being unable still to pass her urine. I drew off a full pint, very light-coloured. Again at 11 P.M. I had to use the catheter, and got as much as on the occasion in the morning—clear, otherwise not remarkable. Next day, she was quite well. This woman, strong and healthy, had never been so troubled before. She had had no stimulants through the day, drinking tea and barley-water, and no large quantities of these. Her diet had been ordinary the day previous, except celery—"a whole stick"—of which she was very fond. The frost about the time had made her favourite very delicious; therefore she ate inordinately. It is traditional hereabout that celery acts upon "the water".

W. THURMANN RAMSDEN, L.R.C.P.Ed., Ravensthorpe.

## THERAPEUTIC MEMORANDA.

### KOUMISS IN THE TREATMENT OF OBSTINATE VOMITING.

KOUMISS has recently been spoken of favourably in the *JOURNAL* in the treatment of obstinate vomiting. I send a brief account of two cases which I treated successfully by it after the failure of other means.

CASE 1.—Miss W., aged 25, came here for the benefit of her health about six months ago, and, when I examined her chest shortly after her arrival, I found that the left lung was extensively diseased. She improved greatly till January, when violent sickness came on. Hydrocyanic acid, bismuth, and other remedies, were used without any benefit, so I determined to try what koumiss would do. I got a supply from Messrs. Chapman, and was very pleased to find that the stomach would retain small quantities of it, and from this time the patient gradually mended. I was anxious that she should take a course of koumiss, as I thought it would do her good; but, unfortunately, after taking three or four bottles, she disliked it so much that she could not continue to drink it.

\* I have related this case at length in the chapter on the Treatment of Pleuritic Effusions, in my recently published work on *Consumption and Chest-Diseases*.

CASE II.—Miss G., aged 60, has suffered from a fibrous tumour of the uterus for the last ten years; but, till January of this year, she has not had any medical advice for four or five years. I was asked to see her then, as she was attacked with vomiting of a most violent kind. I found the stomach was excessively irritable, and could not retain either water or ice. Opium, hydrocyanic acid, champagne, and other things were tried, but immediately rejected. I feared she would sink from exhaustion, and, as a last resource, I determined to give koumiss a trial. It was given in very small quantities, and with the most satisfactory result, as from that time the sickness abated and gradually her stomach was able to retain other nourishment.

I may add that I have used koumiss with great advantage in several cases of phthisis; even in the advanced stages, I have found it grateful to the patient and easily assimilated. One, during the last few days of her life, took it quite greedily, drinking three bottles a day.

C. J. WORKMAN, M.D., Teignmouth.

## PATHOLOGICAL MEMORANDA.

### A LARGE HEART.

IN the JOURNAL of March 30th, p. 458, the *Revue Médicale de l'Est* is quoted as authority for a statement which, I think, needs correction. Referring to a case of sudden death in which the heart was found to weigh 3 lbs. 4.2 oz. av., it is pronounced that this heart "exceeded in size and weight all the recorded instances of *cor bovinum*". The late Dr. Stokes, however, exhibited, at a meeting of the Pathological Society of Dublin (*Reports*, 1868-9), a heart with adherent pericardium which weighed 4 lbs. 2 oz. av. And Dr. Hayden, in his work on the *Diseases of the Heart and Aorta*, besides quoting this case, mentions Allan Burns as adducing the authority of Lieutaud for the description of a heart which weighed five pounds.

GEORGE F. DUFFEY, M.D., Dublin.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN AND IRELAND.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### CONSULTATIONS.

March 28th.—*Tumour of Sterno-mastoid*.—A robust man, aged 44, first observed a hard lump on his neck two months ago; the swelling had since grown larger. On examining the patient, Mr. SAVORY found that the lump the man complained of was in the substance of the left sterno-mastoid muscle, involving chiefly the sternal origin. Its limits, as far as the muscle was concerned, were ill-defined; but it certainly did not extend, or adhere to adjacent anatomical structures. It was solid and very hard. The patient had a sore on the penis, followed by a rash, fourteen years previously. Mr. Savory had tried the usual antisyphilitic remedies for more than a week, without effect; the tumour was harder than most gummata, and, if it continued to grow, its removal was very advisable. Iodide of potassium might be administered for a week or two longer; but if then no good results could be observed, the growth ought to be removed. Mr. Savory determined to act on that decision, his colleagues fully concurring with him.

*Necrosis of Radius*.—Mr. SAVORY brought forward a lad about twelve years of age, who had injured his forearm five months previously. The entire shaft of the radius had necrosed, and there were numerous sinuses; there was good reason to believe that neither epiphysis was involved. In a similar case, where the articular ends were not diseased, Mr. Savory had removed the necrosed shaft of a radius with great success, very firm bone being produced in its place; and the patient regained the perfect use of his forearm. He thought it time to operate in the same manner in this instance, and the rest of the staff were of the same opinion.

*Fracture of both Femora; Yielding of Callus*.—In August 1877, a youth was admitted into Mr. Savory's accident ward, with fracture of the right femur, in the middle third. He was sent to the Highgate Convalescent Hospital after a few weeks, his fracture having united apparently firmly and in good position. But in October, he fell and broke the left femur. Soon afterwards, he was once more able to walk;

it was found that both his thigh-bones were much bent, and he had become very lame. The right femur was much deformed, and the left was almost as bad. The patient was sure that when an infant both his thighs and one leg had been broken, but his assertion could not be clearly verified. Mr. SAVORY asked the opinion of his colleagues as to the proper treatment that ought to be pursued. He believed that forcible bending under chloroform might be employed to straighten both thigh-bones, the union between fractured ends of bones never being very firm for months after the injury, particularly in this instance. —All the surgeons were in favour of forcible straightening; should that not be found practicable, subcutaneous osteotomy would be necessary.

#### MERCER'S HOSPITAL, DUBLIN.

##### CASES DISCHARGED DURING THE MONTH OF FEBRUARY.

(Under the care of Mr. E. STAMER O'GRADY.)

*Intestinal Obstruction: Suspension of Symptoms: Return, with a Fatal Result*.—A healthy-looking woman, aged 23, the mother of two children, was admitted, complaining of abdominal pain with vomiting. There was much tympanitic swelling, and the symptoms pointed to intestinal obstruction. The bowels, however, responded well to enema; and the patient improved greatly, being apparently convalescent on the third day of treatment, and so remained till the fifth day, when stercoraceous vomiting set in, with signs of peritonitis, to which she speedily succumbed. At the necropsy, a fold of peritoneum was found to bind down the small intestine eight inches before its termination in the cæcum. The stricture was so tense that the muscular fibres of the intestine beneath the constricting band had entirely disappeared. The cæcum contained hardened fæces, while the large intestine was empty.

*Intestinal Obstruction from Adhesion to a Morbid Growth*.—The patient was a female aged 28, but looked older. The bowels had been confined five days. The abdomen was large and tympanitic. The symptoms were from the first acute, and developed rapidly, with stercoraceous vomiting. There was no obstruction to the passage of the long enema-tube, which was inserted twenty-two inches; but a digital examination detected a mass of considerable size around the uterus. Abdominal section was performed the day after admission. The patient being placed under the influence of chloroform, the abdomen was laid open freely. After some search, a portion of small intestine was found deep down behind the pubes, adherent to a large morbid mass contiguous to the uterus; and it was evident that this was the mass which had been felt at the previous vaginal and rectal examinations. With some trouble, this portion of the gut was liberated, when the pent-up flatus at once passed through it. The distension of the small intestines necessitated puncture with a small trocar and cannula. The orifice was, for safety, secured with a circular ligature of carbolised catgut. The wound was then closed and dressed as is usual after ovariectomy. The patient was much prostrated before the operation, and was very low indeed at its conclusion. She, however, rallied marvellously, and for some hours matters began to look promising. The vomiting ceased, and she said she felt relieved and comfortable. The improvement, however, lasted but a short time, when sinking and collapse occurred. At the necropsy, it was seen that the obstruction had been thoroughly relieved, and that there was no other constriction of the intestine. There was a small ovarian cyst lying on the new growth, from which the gut had been detached at the operation; this contained a gangrenous abscess, the sac of which had burst and evacuated its contents into the peritoneum. The adhesion of the gut to the parietes had been very slight, and, but for the other complications, it seemed probable that the patient might have recovered.

*Operation for Hare-Lip*.—The patient was an infant aged nine months. The malformation, though single, was attended with cleft palate and considerable projection of the intermaxillary bones. In dealing with the bone-deformity, the internal surface of the protruding mass was made raw, as well as the internal face of the left superior maxilla; then the protruding bone was cut through above, and forced down into position, being retained in position by interosseous sutures of carbolised catgut. The edges of the cleft lip, having been pared with scissors, were united by two hare-lip needles; and a carbolised catgut suture was used at the red margin. The result was in every way thoroughly satisfactory.

*Excessive Salivation stopped by curing a Ranula*.—A young woman five months pregnant suffered severely from profuse salivation, which was attributed to the pressure of a large ranula on the right side. A piece of the cyst-wall of the size of a shilling was clipped out, giving vent to a considerable quantity of glairy fluid. Slight local inflamma-

tion followed, but soon subsided. The salivation then completely subsided.

*Large Nævoid Growth on the Cheek: Ligature and Sutures.*—An infant presented a nævus as large as a couple of walnuts nearly in the centre of the left cheek. It was congenital, of the sebaceous variety, and increasing rapidly in size. It was tied in halves subcutaneously, the ligatures being secured with running points, so as to allow of their being tightened up as requisite. A few setons were subsequently used. Suppuration was thus freely established, and then healing advanced rapidly. After remaining in the hospital a month, some of the mass remained unabsorbed, but the nævus appeared to be cured; and the subsequent account given by the mother is confirmatory of this opinion.

*Compound Fracture of the Tibia: Rapid Recovery.*—A girl ten years of age presented a very oblique fracture of the tibia a little below its centre, the sharp end of the upper fragment protruding through the skin. Lint steeped in blood was applied, and on this a pad soaked in friars' balsam; and the limb was placed in the ordinary fracture-box of the hospital. The wound gave no trouble. The little patient was dismissed with a perfectly sound and well-consolidated limb in twenty-five days.

*Spontaneous Gangrene of Toes: Separation: Recovery.*—In a man aged 42, the little toe of the right foot and the outer surface of the fourth toe were in a state of sphacelus, and the whole foot was extremely inflamed. The patient attributed the mischief to cutting his corns with too sharp a knife. The little toe sloughed off entirely at its proximal articulation. After this, the inflammation of the foot subsided; the wound became clean, and healed by cicatrization.

*Early Operation for Ruptured Perinæum.*—A woman aged 25 had sustained an extensive laceration of the perinæum, opening into the anus, at her confinement, three weeks previous to the operation. On admission, the wound was but slightly healed, the greater portion of its surface on both sides was granulating freely. The operation was planned so as to make broad strips of raw surface, corresponding to each other in breadth, on the opposite sides. Where there was mucous membrane, this was dissected back and saved; but the major portion of the field of operation was in a condition of granulation, and this was dealt with by transfixing these structures with a sharp knife and shaving off the face. The very moderate hæmorrhage soon subsided, when four deep quill-sutures of strong silk and four superficial stitches of carbolised catgut were inserted. The former were removed after eight days; with the latter it was not necessary to interfere at all. The entire wound healed soundly, and primary union occurred, except a very small hole at the posterior extremity; this granulated kindly, and soon closed in. At the time of the operation, the woman was pale, anæmic, and altogether in a condition of depreciated health, a circumstance which adds to the interest of the operation, performed as it was at so exceptionally an early period after the confinement.

*Hydrocele of the Neck.*—This occurred in a small child, two years of age, and was complicated with further deep-seated disease. The growth occupied the right inferior triangle of the neck, and was as large as the closed fist. It was translucent, and presented the other characters of the affection named. The fluid was drawn off by a drainage-tube, and, as it came away, it was evident that a bunch of enlarged glands occupied the deeper portions of the cyst. Some days subsequently, the cavity was injected with tincture of iodine. Much suppurative action of a most unhealthy type followed, numerous abscesses formed and had to be opened, and through the apertures ill-formed pus and sometimes fragments of broken down glands extruded. The child's health was for a time much depreciated, and at one time there were symptoms of blood-poisoning. Eventually, however, respirative action became established, both locally and constitutionally. After a stay in the hospital of nearly two months, the child was allowed to return to his country home, apparently in a fair way to do well. Some of the inflammatory swelling of the matted tissues still remained, and was being slowly absorbed.

**ASTON MANOR.**—The population is estimated at 46,462; the birth-rate at 43.2 and the death-rate at 17.5 per 1,000 inhabitants. Mr. May having expressed his conviction that the building by-laws should be strictly enforced, an assistant-surveyor has been appointed to see them carried out. Mr. May says that this is absolutely necessary, as he has found families in rooms where the paper would not stick, and the plaster was running down with water; so that it is a wonder that the death-rate was so low. The mortality of infants under one year was 13 per cent. of the births, and the zymotic death-rate was 3.4 per 1,000. Sanitary work appears to have been actively carried out, and some new sewers have been constructed.

## REVIEWS AND NOTICES.

NOTES ON THE SURGICAL TREATMENT OF AORTIC ANEURISM. By JOHN COCKLE, A.M., M.D. Pp. 43. J. and A. Churchill.

OUR profession is often twitted with the haphazard way in which its most successful weapons against disease have been discovered; and, in truth, the data for rational therapeutics have as yet scarcely emerged from their concealment in obscure or inaccurate physiology. We know this so well, that remedies suggested on physiological grounds are still looked at askance, although the time has at last come when this reproach is passing away from us. The operation of ligature of the carotid artery for aortic aneurism will not suffer discredit, however, from having been suggested by any *à priori* reasoning. No remedy in medicine or surgery has ever originated from observations less premeditated. On the one hand, the association of consolidated aortic aneurism with occluded left carotid had been more than once observed in the dead-house and the dissecting-room; on the other, ligature of the same vessel had been successfully performed for the cure of what had been erroneously diagnosticated as carotid aneurism, but which proved to be an aortic sac. It is to Dr. COCKLE that the credit is undoubtedly due of having suggested to Surgery an operation which, based upon *post mortem* findings and the clinical errors of the past, has yet so far been justified by practical results. It is a good feature of the pamphlet before us that, near its commencement, the author boldly observes that he has no theory to offer us as to the exact manner in which the measure he strongly advocates brings about the consolidation of the aneurismal sac. Dr. Cockle is, indeed, not satisfied with any of the suggestions that have been offered. He does not find in the facts of cases that diversion of blood-current will suffice to explain the occlusion of the aneurism; for it would appear that the left carotid need not spring directly from, or even very near to, the aneurism, for the effect to be observed; the operation having proved useful in cases in which the disease involved the ascending or right portion of the aortic arch. And, for this same reason, it cannot be held that extension of clot downwards from the tied vessel is essential for the cure. That an influence should be transmitted to the lining membrane of the sac is a supposition sufficiently indefinite to be beyond criticism. It may be that the true *rationale* of the treatment includes all these, and, in addition to them, that absolute repose which an important surgical operation entails.

But we are for the moment assuming more than is, perhaps, yet permissible; viz., that the operation is to be commended as a method of treating aortic aneurism. And this is the very question with which the pamphlet before us deals as fully and fairly as present experience will allow. In answering this question, Dr. Cockle refers to three sets of observations: firstly, those in which the occlusion of the artery, coinciding with the formation of laminated clot, has been effected by a natural process—cases which have for the most part come to our knowledge from *post mortem* inspections; secondly, cases in which the artery has been tied for supposed carotid aneurism, which has, however, turned out to be aortic aneurism; thirdly, cases in which the vessel has been successfully tied with the definite purpose of causing consolidation of an aneurism affecting the arch of the aorta. Several cases of this latter kind have now been published. Mr. Christopher Heath first adopted the treatment at Dr. Cockle's suggestion in 1872, and has subsequently repeated it on two occasions. Mr. Holmes and Mr. Maumder and other surgeons have also more recently performed the operation. The results of this operation must, like those of any other surgical measures, be compared with those of other treatments of a disease which no pathologist can admit to be curable. The important question is, *When* is this severe measure to be adopted? Dr. Cockle is scrupulously careful in pointing out the place ligation should hold in the treatment of aneurism; viz., that of a *dernier ressort*, "last on the list of therapeutic means". But, be it remembered, this in no way sanctions the postponement of the question of operation to a period when the patient is too exhausted for its adoption. Here lies, indeed, the great practical difficulty in deciding upon this procedure. The operation itself is by no means free from dangers; secondary hæmorrhage, cerebral anæmia, and possible cardiac syncope, being those apt to arise. But the sufferings from the disease are so terrible, and the relief has in some cases proved so prompt and long enduring, that the fear is lest, as the operation becomes better known, it may be too eagerly adopted, without very careful consideration of the merits of each case, and before a fair trial has been given to other measures. A careful perusal of the pamphlet before us, however, will tend to lessen

this danger; for it is written with a full sense of responsibility, and with a due regard to those other methods of treatment which come within the province of the physician. That the aneurism be sacculated, is laid down as essential to success; that it be situated near or at the root of the carotid, as of much, but not essential, importance. The condition of the other great vessels of the neck must also be carefully looked to, in order that diversion of the left carotid blood-stream may not seriously interfere with the nutrition of the brain.

#### THE QUESTION OF REST FOR WOMEN DURING MENSTRUATION.

By M. PUTNAM-JACOBI, M.D. Illustrated. Pp. 232. Smith, Elder, and Co. 1878.

This essay, to which was awarded the Boylston Prize of Harvard University for 1876, is one well worthy of attention. The phenomena associated with menstruation are here carefully considered. In regard to it, Dr. PUTNAM-JACOBI holds the older and at the same time the newer view, that menstruation is "an excess of nutritive force in the sex upon whom devolves the greatest cost of reproduction". She rejects the theory that menstruation depends upon ovulation. The old view is upheld with some minor modifications against the "ovulation theory" distinctly formulated about 1845, which construes the menstrual hæmorrhage as a subsidiary phenomenon entirely dependent on the periodical dehiscence of ovules. "Around this theory has clustered the most brilliant gynaecological literature of modern times." The dehiscence of ovules, however, does not commence at puberty synchronously with the appearance of the menses, but goes back to the second or third year. "The ovule, germinal vesicle, and germinal spot have almost the same dimensions in the child as in the adult; but in the latter the number of ripe Graafian vesicles is somewhat larger than in the child. During childhood, the ripe follicles undergo a retrograde metamorphosis without bursting." Not only this, but the dehiscence of the ovule is not, in the human species, exclusively associated with menstruation. The view maintained by Dr. Putnam-Jacobi is, that there is a long gradual preparation in the woman before she becomes actually fit for positive reproduction. The dehiscence of ovules has gone on for years before this stage of fitness is reached. "The woman buds as surely and as incessantly as the plant, continually generating not only the reproductive cell, but the nutritive material without which this would be useless, whether or not either be utilised in further development. Reproduction in the human female is not intermittent, but incessant; not periodical, but rhythmic; not dependent on the volitions of animal life, but as involuntary and inevitable as are all the phenomena of nutritive life." Dr. Putnam-Jacobi holds that "it is erroneous to study the menstrual flow as a process complete in itself, or to attribute it to a simple congestion or a prolonged erection. It is only the terminal change of a cycle of changes, which begin at the cessation of one menstrual flow and end with the cessation of the flow next following. There is no period of uterine rest; but the organ is ever undergoing those changes which either make it a fit receptacle for the ovum when impregnated, or which prepare it to carry off the ovum when impregnation has failed. If any one stage of the month could be appropriately called a period of uterine inactivity, it would be the bleeding period, for it is then that the mucous membrane ceases to develop and undergoes fatty degeneration." Again, "the menstrual hæmorrhage is to be regarded as the simple equivalent of an accumulation effected by a constantly rising wave of nutrition, primarily (in all probability) affecting the nervous and muscular systems through which the blood circulates. If richer blood circulates in a slightly increased quantity and under a higher pressure through the nervo-muscular organs, the nutritive movements in their tissues are accelerated, and the acceleration is marked by the increase of urea. When, in virtue of the rhythmic movement inherent in their form of nutrition, a portion of the nutritive fluids of women becomes in excess of their individual needs, this excess begins to accumulate in the circulation, until finally, the tension becoming excessive, the closed system gives way at its weakest point—the blood-vessels of the fattily degenerated uterine decidua—and hæmorrhage occurs."

So much for the phenomena of normal menstruation.

"On the hypothesis that the menstrual period represents the climax in the development of a surplus of nutritive force and material, we should expect to find a rhythmic wave of nutrition gradually rising from a minimum point just after menstruation to a maximum just before the next flow. The traces of this rhythmic wave should be measured by the consumption of oxygen, the excretion of carbonic acid and of urea, by the tension of the arterial system, the vital capacity of the lungs; possibly also by the dynamic force of muscles." Such is the preface to a series of inquiries made on six women for a lengthened period. It was found that, "during the few days preceding the men-

strual flow, the excretion of urea is generally increased above the average at intermenstrual periods. In the majority of cases, the urea fell during the flow"; but in others (a minority) it went over. The temperature rises from one-eighth to eight-tenths of a degree during the week preceding menstruation. It falls gradually during the flow, but in the majority of cases does not even then reach the normal average. With the dynamometer test, the muscular strength was increased in seven cases during the flow, less in other seven, and exactly the same in one. A large series of sphygmographic tracings illustrate the question of the state of arterial tension. There is an increase of plenitude and tension up to the time of the flow, but after a few hours of the hæmorrhage the tension is markedly lowered. The lowest point is reached immediately after the cessation of the flow, after which the rhythmic wave of plenitude and tension rises again gradually to a maximum in the premenstrual week. "These observations, if confirmed by others more numerous, should show that in all respects the intermenstrual, and especially the premenstrual, period represents a pregnancy in miniature." From these observations, we can readily comprehend the truth of the following statement. "Now, in the majority of women, the week preceding menstruation is a period of increased vigour, consciousness of increased nervo-muscular strength"; and with some women "the increased feeling of energy begun in the premenstrual week is extended throughout the menstrual flow". The conclusion of all this is that, in typically healthy women, the week of the menstrual flow is not a special time of trial to them; and that they may work during this period with impunity.

But all women are not typically healthy women, and it may be well to see what proportion are. Accordingly, a thousand tables were sent out, asking sixteen questions bearing on the subject of menstruation. To these two hundred and sixty-eight answers were returned. Out of this number, ninety-four, or 35 per cent., suffered neither pain, discomfort, nor weakness during the menstrual flow; and twenty-eight only suffered slightly or occasionally, but not sufficient to interrupt their daily vocations. There remain, then, "one hundred and twenty-eight women, or 47 per cent. of the whole, to whom menstruation was a seriously painful, therefore morbid, process". As to whether they had so suffered long or briefly, cannot be gone into here. This is a large percentage of women to be more or less disabled during a definite period of each menstrual cycle.

We may now review the question of the effects of various forms of labour upon women during the catamenial flow, and the effects of these forms of labour upon that flow. The effects of muscular exertion upon the health of women are in accordance with the theory of the supplemental nutritive wave advocated here. The robust health of country women, who work hard out in the open air, and their freedom from catamenial troubles, are well known. It is only when the health is broken down from various causes, as excessive childbearing, that they begin to suffer from menstrual troubles, as a rule. The increased muscular development so induced furnishes a sum of nutritive material stored up in the muscles, ready at any moment to be appropriated, either for the evolution of motor force in muscular contractions, or for the development of "the supplemental wave of nutrition destined to terminate after one month in menstruation or after nine months in parturition". Muscular work, then, does not deteriorate the health of woman, but rather is an advantage to her. But when work necessitates a constrained position, and interferes with the return of blood from the pelvis, then it does affect the health of women. Celibacy, especially in the upper classes, has an injurious effect upon the health of women; so too does work which entails "forced fixity of attention" for a lengthened period. Dr. Putnam-Jacobi states frankly "that as the characteristic bodily defect of women is lack of muscular strength, so their characteristic mental deficiency, taken as a class, is lack of power of attention". If their work thoroughly excite their sympathies, then very hard work may be accomplished with ease. This is true of both men and women, but more so of the latter; and "simple continuous work which is either indifferent or repellent will, if pursued for a long time, be followed by a 'breaking down' in health. The first symptom of such breakdown is backache; the second a greater or less degree of pain at menstruation." Female teachers are notoriously subject to catamenial disturbances.

The kind of rest needed by women consists in interruptions every two or three hours, not every three or four weeks. Thus, as instanced, domestic servants have much better health than women in other employments involving long hours of attention to the same subject. In schoolgirls and young persons called upon to perform mental work to order (i. e., without spontaneity), this question applies specially. In adolescence, and during the first years that the reproductive wave of nutrition is being formed, mental work exacted "in excess of the capacity of the individual may seriously derange the

nutrition." The influence of fixed attention upon the health of females is a matter calling for more general recognition than is given to it either in girls' schools or in places of business.

As to the practical inferences to be drawn from the foregoing considerations, one is, that female work should be intermittent *at short, not long intervals*. "It is useless to rest during the few days of the menstrual flux, if work be maintained strenuously during the intermenstrual period." The form of labour exercises a marked influence, muscular labour doing good, and counteracting the evil effects of fixed attention, even in perfectly healthy women. Even they "do work better and with greater safety to health when their work is frequently interrupted; but these intermittencies should be at short intervals and lasting a short time, not at long intervals and lasting longer. Finally, they are required at all times, and have no special reference to the period of the menstrual flow. It remains true, however, that in our existing social conditions 46 per cent. of women suffer more or less at menstruation; and that for a large number of these, when engaged in industrial pursuits or others, under the command of an employer, humanity dictates that rest from work during the period of pain be afforded where practicable." With this sentence the work concludes.

It is impossible to escape from the strong attractiveness of the views expounded here so vigorously, yet with such good taste and delicate perception. This view of menstruation being a supplemental wave of nutrition passing through rhythmic cycles, rather than a general state of vascular excitement dependent upon and governed by the changes going on in the ovaries, is probably true. Ovules may form in childhood, and menstruation persist for years after double ovariectomy; yet the relations of the changes in the ovaries to the general condition cannot be overlooked. If the menstrual flow be merely the natural result of a wave of nutritive material coming to its climax, how is it that it so commonly occurs before the growth is completed? How is it too that, as a rule founded upon close observation in the out-patient room, a free catamenial flow in young girls is usually found in small girls; and that well-grown girls rarely are excessively unwell until growth is completed? The influence of the ovary in determining excessive menstrual loss is surely beyond doubt; for in these cases of early menorrhagia there is usually a tender enlarged ovary. Arrest of the excessive loss by bromide of potassium not rarely results in resumed growth, until a goodly addition of stature is attained. While admitting the view advocated here as to the cause of the menstrual hæmorrhage, it must be said that the influence of the ovaries seems to be thrown too much into the background, and the association betwixt the dehiscence of the ovule and the catamenial flux is underestimated. The catamenial loss is not in many women determined, as regards its amount, by the excess of nutrition in the system, but rather keeps them in a condition of semi-starvation; and restoration of health is only attained by limiting the loss. Nevertheless, the views stated by Dr. Putnam-Jacobi are of great value as pointing out what is too little recognised; viz., that amenorrhœa is often a piece of conservative economy when the system cannot afford the loss, and that its real treatment is that of the system generally; and that the reappearance of the menses is but the evidence of the general improvement. What is further said as to the occupation, the forms of labour, and the hours of labour for women, is worthy of considerable attention.

This essay is a piece of excellent work. The facts are well arranged; the language is much above the average; the good taste all that could be wished.

## NOTES ON BOOKS.

We hail with great satisfaction the appearance of the first number of the *Journal of Physiology* (Macmillan and Co.), edited by Dr. Michael Foster of Trinity College, Cambridge, with the co-operation in England of Professor Gamgee of Manchester, Professor Rutherford of Edinburgh, Professor Burdon Sanderson of London, and in America of Professor H. B. Bowditch of Boston and Professor Martin of Baltimore. Its appearance is at once indicative of the hopeful progress in physiology which has been evident of late years in this country, and with which are especially identified the names of the four English editors—the scientific descendants of Professors Hughes Bennett and Sharpey—to whom, in this country, is due so much of the physiological impulse which has already borne good fruit. We cannot here undertake to indicate or criticise, by way of analytical review, the papers contained in this first number; we shall content ourselves now with a list of them, from which alone will be apparent the good work represented by this periodical. Its publication marks a new era in the progress of scientific medicine

in the English-speaking countries; and such is the earnestness and activity of the schools over which the editors preside, that there is little fear of any lack of material. We only hope that enough material support will be found amongst the more highly educated members of the medical profession and the more earnest students of physiology to afford to this scientific periodical a sound basis of commercial success. It must have the best wishes of every thinking member of the profession, and we hope that those wishes will translate themselves into a substantial form. It is sufficiently notable that Oxford alone of the great Universities is unrepresented in this *Journal of Physiology*, as we fear it must be content to remain but partly represented in the progress of scientific medicine generally until some great change is made in the present state of decadence and discouragement of medical study in that great University. This absence of Oxford from that sphere of scientific medicine and biological progress, in which the greatness of her resources well fit her to be foremost, is of itself hardly less eloquent than any protest which we have recently published on this subject. On the other hand, the forward position of Cambridge in the van of the scientific movement in medicine is greatly to her credit, and especially honourable to Dr. Foster, and let us add also to Professor Humphry, whose labours in founding and carrying on the *Journal of Anatomy and Physiology* were the precursors, and are still the adjuncts, of the work of Dr. Foster and of the enlightened liberality of Trinity College, of which he is the Prælector of Physiology. The articles contained in this first number are: An Account of the Anatomy and Physiology of Batrachian Lymph-Hearts, by J. Priestley; Concerning the Effects on the Heart of the Alternate Stimulation of the Vagi, by A. Gamgee and J. Priestley; Note on Fechner's Law, by Trotter Coutts; Hyperplasia of the Muscular Tissue of the Lungs, by W. Stirling; Some Remarks on the Formation of Ferment in the Submaxillary Gland of the Rabbit, by J. N. Langley; Concerning the Effect on Frogs of the Arrest of Circulation, and an Explanation of the Action of Potash Salt on the Body, by Sydney Ringer and W. Murrell; The Physiology of the Salivary Secretion, by J. N. Langley; Does the Apex of the Heart contract automatically? by H. P. Bowditch; Preliminary Note of further Investigations upon the Vaso-Motor Nerves of Striated Muscle, by W. H. Gaskell; and a classified list of books and papers of physiological interest, published this year. The collaboration of the American editors is a feature of great interest. Flint, Bowditch, Ois, and many other of the younger American school show no small capacity and taste for physiological research, in which they have had good European training; and America will, we expect, contribute much valuable matter to this journal.

*Mind*. No. IX. London: Williams and Norgate. 1877. This number is not, especially to medical readers, so interesting as usual, although it contains some valuable contributions. The opening paper is an interesting *résumé* by Mr. Sully of the results of recent physiological research concerning Vision, with especial relation to theories of the Perception of Space. The main facts ascertained by Helmholtz and Wundt are carefully collected in the present number, and we are promised a discussion of the resulting theories in the next. The second paper is a criticism, by Mr. Croom Robertson, of Mr. G. H. Lewes's Physical Basis of Mind, discussing at length the theory of Animal Automatism and the "Reflex Theory", both of which we understand the two psychologists to reject, though in a slightly different way. But by far the most interesting paper in this number is that by Professor W. R. Clifford, on the Nature of Things in Themselves, where, in his clear and frank fashion, he throws out some very curious conclusions. The reader will find some strange words—such as "Ejects" and "social objects"—which we venture to think so clear a writer might have dispensed with; and if he believe Professor Clifford, he will come to the strange conclusion that the "Thing in Itself"—our old friend the German *Ding-an-Sich*, the despair of all metaphysicians—is really nothing else but "an elementary feeling", or, in the barbarous language of modern psychology, "*mind-stuff*", and that "matter is a mental picture in which mind-stuff is the thing represented". We venture to think that this will be, to most readers, at least a novel view. Among the shorter papers at the end, will be found some good notes on the Colour-Sense, à propos of Mr. Gladstone's recent article in the *Nineteenth Century*.

*Revue Philosophique*. December and January. Paris: Germer Baillière et Cie. The first number of this third year of the French Review opens improvingly with a *réplica* in French of Mr. Herbert Spencer's article on Ceremonial Government, the first of a series of sociological studies which are to appear, we understand, in six languages simultaneously—a proof, at least, that Mr. Spencer has a wide audience. The other important articles are a long and polemical

paper by M. Delbœuf directed against Fechner's new book on what they are pleased to call *The Law of Psycho-physics*, and a lively account, in which our readers will probably take more interest, of two speeches relating to the sphere of the medical science in philosophical inquiry recently delivered by MM. Helmholtz and Du Bois Reymond. There will also be found among the reviews a long and appreciative article upon Mr. Grant Allen's *Physiological Aesthetics*, and other interesting papers. The December number, which is also before us, has no great interest for the mere physiological student. There is, however, a good article, following out a previous series, upon Lange, the author of the *History of Materialism*, besides an uninteresting and theoretic attempt to suggest a physiological explanation of Common Sense, by F. Pauthan. The best paper in the volume is the concluding part of an essay, by M. Scaïlles, on the Aesthetic Philosophy of von Hartmann, in which will be found his interesting criticisms on *Roméo and Juliet* and *Faust*.

## REPORTS OF SOCIETIES.

### PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, APRIL 2ND, 1878.

CHARLES MURCHISON, M.D., LL.D., F.R.S., President, in the Chair.

#### DISEASES OF THE LYMPHATIC SYSTEM.

THE discussion on the diseases of the lymphatic system was resumed.

*Lymphadenoma.*—Mr. NUNN exhibited microscopical preparations and drawings of examples of—1. Simple hypertrophy of an axillary lymphatic gland; 2. Secondary affection of a popliteal lymphatic gland, the primary disease having been large-celled sarcoma of the fibular periosteum; 3. Secondary affection of the axillary lymphatic glands, the primary disease having been cancer of the breast; 4. Secondary affection of subcutaneous lymphatic tissue, from the neighbourhood of the scar after amputation of the breast seven years previously, the primary disease having been tumour of the breast, presumably cancer. The first specimen showed an unlimited production of lymphoid corpuscles, without any tendency to arrangement in groups. The second showed an equally unlimited production of the large cells of the sarcoma, without tendency to arrangement in groups. The two last showed cells of two distinct characters, namely, the lymph-corpuscles and the epithelium-like cancer-cells; these latter being arranged in groups and surrounded by the lymphoid corpuscles. In reference to the questions raised by Dr. Wicks, Mr. Nunn said that, whatever might be the precise nature of the relation of lymphadenoma to cancer, a very suspicious companionship would be found in cancer between the cancer-cell and the adenoid growth. He thought, in respect of prognosis, that the general invasion would be found to be more rapid, and the fatal termination to occur earlier in adenosis than in cancer.

*Hyperplasia of the Axillary Glands, with Leukæmia.*—Dr. R. O. JONES gave an account of the case. It occurred in a man aged 50, of good family history, and who had always been healthy, except some infantile troubles. He had never had syphilis. A small lump appeared in the axilla in 1866. In 1877, he began to suffer from eczema of the face and lower extremities. He then had pain in his liver and back, a glazed tongue, diarrhoea, depression, and loss of sleep. The skin over the lump became thick, brawny, and dark; while a mass of glands enlarged so as to obscure the clavicle. In time, opiates failed to procure sleep, and he became much worse. The axillary tumour was of the size of a Seville orange, and movable. Edematous swelling set in. The temperature rose to 100 deg. in the morning, and 102 deg. in the evening. He had chilliness rather than distinct rigors. The liver and spleen were not enlarged. There was no hæmorrhage from any of the mucous surfaces. On examination under the microscope, the white blood-corpuscles were found in great excess; in one corner of the field, there were thirteen white corpuscles to one red one. A gland behind the left angle of the jaw enlarged to the size of a hen's egg, and the skin over it was tender. The temperature then rose to 101 deg. in the morning, and 103 deg. in the evening; and the man died from loss of sleep and exhaustion. On *post mortem* examination, two tumours of the size of Seville oranges were found. One was filled with soft material like brain-tissue; while the one behind the ear was suppurating. The right lung was covered with thickened pleura. In the upper lobe of the left lung, was an old cicatrix, telling of healed vomica. The bronchial glands were not enlarged. The capsule of the liver was thickened; and the spleen, otherwise healthy, was shivelled. The rest of the viscera were natural. On microscopical examination of the tumour, there was found a hyperplasia of the gland-tissue, with large

flat irregular shaped cells, found in the largest number near the capsule of the gland. In another section, the fibrous tissue was found in excess. The case was of interest, as showing that leukæmia might occur with lymphadenoma, though this was denied by some authorities. The spleen and liver were not examined microscopically. The case was clinically striking, too, as, if the blood had not been examined, it would have been difficult to find a cause of death. The high temperature and the persisting diarrhoea were of interest too. Leukæmia was not due to these growths, but to defective formation of blood-corpuscles. In answer to a question put by the President, Dr. Jones said the tumour in the axilla did not enlarge to the end.

*Intestines from a Case of Lymphadenoma.*—Dr. SIDNEY COUPLAND exhibited these intestines, which came from a young woman, who suffered from uterine pain and diarrhoea, with vomiting, under which she sank. The evening temperature was high. Lymphadenoma was not suspected in life. The case was thought to be one of chronic enteritis. On *post mortem* examination, the stomach was found thickened and mammillated. In the intestine, the mucous membrane was infiltrated, especially at the upper part; this was not limited to the solitary glands or Peyer's patches. In the large intestine, there was ulceration of a superficial character; similar ulceration was found in the new material of the small bowel. The mesenteric glands were affected, but were neither softened nor caseating. Some other glands were enlarged in the cervical and inguinal regions; and one was found under the peritoneum. This condition of the intestines was uncommon. It had been figured by Cruveilhier in a case where the patient sank with chronic diarrhoea.

*Splenic Leukæmia, with Carcinoma.*—Dr. WHIPHAM related a case of a man aged 25, who in 1876 noticed a lump in his abdomen. He was in good health till his admission into hospital, when he began to fall away, had nausea and headache, and was shifted from the surgical to the medical wards. On examination of the blood, leucocytes were found to be more numerous than the red blood-corpuscles. The man then had giddiness, and heavy perspirations. His lungs were normal, but his respirations were 37 in the minute. His heart was natural, but his pulse was 104 per minute. In his abdomen, there was a large tumour on the left side, extending upwards nearly to the nipple and downwards to the inguinal region; it then extended over to the right side. There was albuminuria. The day before his death, he became agitated, and complained of weakness; his face was suffused; and he had great dyspnoea before he died. At the necropsy, the body was found well-nourished, with a blush over the skin, most markedly of the head and neck. The left pleura was adherent. The lungs were congested, and in some degree solidified in parts. The heart weighed fifteen ounces. Inside was a pale white clot, with pale red fluid. The vessels generally were filled with a yellow coagulum. The liver weighed one hundred and twenty-eight ounces; the kidneys, ten and eleven ounces respectively; and the spleen, seventy-eight ounces; it was hard, tough, and traversed by a white network throughout. The brain and cord were normal, except that the vessels were filled with yellow coagulum. The glands were not enlarged. Microscopic sections were exhibited from this case, and drawings sent round. The liver was pale and firm, but otherwise normal to the naked eye; but, after immersion in spirit, it was found studded with nodules. On microscopic examination, these nodules were found to consist of a new growth, with large uninucleated cells. The majority of these cells were columnar. On section, the growth was seen to be composed of an alveolar stroma, irregular in shape, like that of true carcinoma. True morbid appearances were noted. At the margin of the liver, the hepatic tissue was compressed; in other parts there was a granular matrix, in which were embedded leucocytes and liver-cells, with vacant spaces. In places, the leucocytes were found near the vessels, as if they had migrated therefrom. In the spleen, there was a great amount of hardness, due to old and recent extravasations of blood. In one portion, there was a coarse reticulum of fibrous tissue. This extended mostly from the arteries, and destroyed the spleen-tissues. Blood-vessels were found, with thickened walls. The vessels of the alveolar walls of the lungs were filled and much distended by leucocytes. In the alveoli was found a semi-transparent structureless material, which had shrunk, owing to immersion in spirit, and consequently in many places presented an appearance as of vacuolation. The kidneys were natural. The muscular tissue of the heart was normal; but its vessels were full of leucocytes. With the exception of the same condition of their vessels, the brain, spinal cord, and sympathetic ganglia were healthy. An examination of the sternum was made, and its medullary spaces were found filled with leucocytes. The clot in the heart was full of leucocytes, some with two or three nuclei. The question of the relation of the leukæmia here to the carcinoma might be raised. He considered that, though many arguments might be ad-

duced as opposed to the idea of the carcinoma being a local manifestation of the blood-disease, yet the presence of multinucleated cells in the blood was certainly suggestive of a connection between the two. The leukaemia was certainly not secondary in this case; and, on the other hand, leukaemia was not found in old-standing carcinoma.

*Specimens from Leukæmic Viscera.*—Dr. GOODHART brought forward a series of cases as follows. A child of fourteen months old was admitted to Guy's Hospital with whooping-cough, which, after lasting for some months, terminated by the development of tubercular meningitis. At the *post mortem* examination, a large caseous mass was found in the bronchial glands, and a corresponding invasion of the adjacent lung by similar material. There was general tuberculosis. The second case was that of a girl aged 3, admitted for a local lymphadenoma on one side of the neck. This was excised by Mr. Bryant; and the patient left the hospital well. The third case was that of a boy aged 6, who was admitted under Dr. Pye-Smith for paraplegia. This patient (as also the preceding one) appeared to be in fair health; but, after some little time, he died of pneumonia. The *post mortem* examination revealed a large lymphomatous growth at the root of the neck on the right side, which infiltrated the muscle, periosteum, and adjacent textures, grew inwards to the spinal canal, and caused paraplegia by direct pressure upon the cord. But this was not all; at the root of the lung on this side was a caseous gland, the result of a bygone chronic inflammation, which suggested some local and persistent chronic stimulation to the glands in the neighbourhood, and a direct relation as cause of the old disease to the new. The fourth case was one of chronic disease of the knee leading to caseous changes in the femur and inguinal and lumbar glands of the same side, to caseation of the mediastinal, cervical, and axillary glands, and to general tuberculosis—a case of Hodgkin's disease closely allied to general scrofulosis. The next case was one of Hodgkin's disease, of which Mr. Hutchinson gave some details later in the evening; and the last was an example of general enlargement of the glands and spleen associated with leukaemia, which came under the care of Dr. Frederick Taylor, and which had been previously before the Society; the point particularly alluded to now was that the growth was generalised and infiltrating. These six cases, said Dr. Goodhart, were types which the members of the Society would all recognise as well marked examples of most of the diseases of the lymphatic glands. There was the local chronic inflammation, the local simple tumour, the local malignant tumour, and parallel with the local series ran a generalised one, the diffused chronic inflammation, the generalised simple tumour, the generalised malignant tumour; but, though these types were sufficiently distinct to give well marked clinical groups, still they each and all showed grades so fine between them that it was impossible in discussing their pathology to avoid reviewing the whole series. Allusion was then made to allied processes in other tissues, how in skin, connective tissue, or bone, we were familiar with the local irritation or inflammation merging into the simple growth, and this again into the infiltrating growth by such delicate transition that it could not be said where inflammation ended and growth began, where simple growth ended and malignancy commenced. The lung and serous membranes afforded like frequent examples of chronic irritation ending in localised tumour, and generalised also, if tubercle might be called a tumour. Additional light had been thrown upon such processes by experiments on the lower animals, which showed that, by varying the intensity of the local stimulus, the result might be made to vary from an acute abscess through caseation to chronic induration, local and general tuberculosis. To this process, the term infective had been applied by Dr. Sanderson and others; and, inasmuch as the processes of cell-growth or tumour-growth were of the same kind, if not of the same degree, Dr. Goodhart would, as had already been done by Dr. Greenfield and others, apply the term infective to lymphadenoma. The clinical history was quite in harmony with this. Most of these cases began in one or other gland-region, and gradually spread over the whole body. But, whether this were so or not, at any rate, this much was clear, that the process of all growth from inflammation to cancer was so similar in all the tissues that, without knowing anything of the lymphatic glands save that they existed, it would have been possible to predicate all the diseases now known to exist in them by the study of other tissues. The argument to be drawn from this was, that the leukaemia must be something quite independent of the process of growth; it might and probably did arise owing to its occurrence, but it was in no case more than a superadded or late and non-essential symptom. But Dr. Wilks had raised the question whether leukaemia did occur in these cases; and Drs. Wilks, Greenfield, and Gowers had all agreed upon this point, that the results of their observations were negative. His experience quite coincided with theirs. He had examined the blood in many cases of lymphadenoma, and had hardly ever had any success; but, at the same time, the original teaching of Virchow could not be forgotten, that lymphatic

leukaemia had only a moderate enlargement of the spleen or none at all, and much glandular swelling, and the white corpuscles in the blood were smaller and much more numerous. That group of symptoms, though not frequent in proportion to the other groups, still did exist, and such cases were on record. The facts were sufficient evidence of the occasional occurrence of leukaemia in glandular disease, and more might be made than had been of the *a priori* argument that physiologists were agreed that the lymph-glands elaborated and discharged white corpuscles into the blood. The fact that the spleen was enlarged did not have much weight, because the enlargement was very moderate only, such as might be expected to occur from secondary activity or overwork induced by an unusual activity of the glands, in the same way as Dr. Greenfield and others hold that the glandular swellings in splenic disease were due to stuffing of their parts with the splenic cells. But it was argued that this group of symptoms was seldom found. The reason of this was not far to seek; a large proportion of the lymphomatous growths tended to rapid caseation; another large proportion tended to fibrous induration; and yet others were so purely local after a time that they had no connection with the general glandular system. These facts were in harmony also with the occasional occurrence of leukaemia in malignant tumours of other kinds, as mentioned by Dr. Whipple, and also with the occasional occurrence of suppurative leukaemia. Some observations were mentioned on the latter head made by Dr. Moxon and Dr. Goodhart on the blood of septic fever, which went to show that a slight excess of white corpuscles was occasionally present in fever and other conditions, but never such as to satisfy the definition of leukaemia insisted on by Dr. Wilks. Turning, then, to splenic leukaemia, a case was given, sections of the viscera being exhibited under the microscope, which went to show that leukaemia in splenic diseases also was no more than a late symptom. It was that of a child aged ten months, who came under treatment at the Evelina Hospital for Children. At the first visit, and for three months afterwards, splenic enlargement and pallor were the only symptoms; and then leukaemia (two to three hundred white corpuscles in each field) supervened; and the child died not long afterwards. The specimens were exhibited under the microscope, and showed well marked changes. It had long been thought that ague might have some action in causing the leukaemia; but sufficient attention had hardly been attracted to this, because, perhaps, so large a proportion of leukaemic cases gave no history of ague. Dr. Gowers had made a most important statement on this head, which showed that 25 per cent. of all the cases had suffered from ague, but splenic enlargement other than malarial was not very uncommon, and the case narrated seemed to show that a non-specific splenic enlargement, if sufficiently prolonged, might cause leukaemia. Splenic enlargement was by no means uncommon in childhood from a variety of causes; and, being also exceedingly chronic, it might well be that some of these cases also go on and on and eventuate in leukaemia in the young adult. However this might be, chronic enlargements of the spleen, of whatever kind, if persistent, should be added to those produced by ague as possible factors in leukaemia. There were cases also, of which two such were mentioned, where the spleen was very large, and there was caseation of the glands with general tuberculosis. These have died without ever having leukaemia; yet, the distribution of the disease and the presence of tubercle showed that the two classes of cases must be closely related; and Dr. Goodhart regarded these as cases of leukaemia dying without any change in the blood. From what had been said of many cases of splenic disease, there would be, of course, no necessity for the development of the leukaemia; and fibrous induration, which was not uncommon, would show but little tendency to discharge increased corpuscles into the blood. Such discharge would be likely to occur in the more fleshy and pulpy conditions of the organ. With regard to the quantity of corpuscles to which the term leukaemia should be restricted, it was admitted that the term would unwisely be applied to only a small proportion of these corpuscles; but, bearing in mind the facts and arguments adduced, it was thought that there might be many states earlier in leukaemia than the extreme state now satisfying that term; and, if the slight excesses should be carefully recognised and recorded, we might in the future detect the earlier approach of the disease. With regard to medullary leukaemia, in two cases out of eight only had anything been observed at all like true leukaemic growth in the bones. In these, the masses were certainly pus-like in appearance and peculiar. But, in these cases, like most of those recorded by Neumann and Möser in Germany, the spleen being enlarged, the condition might have been, and according to Dr. Goodhart probably was, secondary. He did not think much would be learnt on this point from the side of cases of enlarged spleen. If any case ever came towards proving a medullary leukaemia, it must be in some such group as that of primary bone-tumour, diffused lymphoma of bones, etc., which are somewhat rare and difficult to diagnose during life. Still, by a careful

outlook, such cases might be found, and some useful observations made.

Mr. HUTCHINSON gave some particulars of the case of his to which Dr. Goodhart had referred. A lady of middle age, residing near Bath, had been the subject for many years of large glandular swellings in the neck. They never showed any tendency to suppurate, and no attention was paid to them. At length, she had an illness, attended by great pain in the back of the neck and other symptoms, which were supposed to be hysterical. When Mr. Hutchinson saw her, after five months' illness, she could scarcely walk, and her sight was very defective. The ophthalmoscope showed optic neuritis. Some enlarged glands were found in the axillæ as well. She had subsequently loss of identity, and became insensible. The necropsy showed numerous small masses of lymphadenomatous growths in the pia mater in various situations. The brain had been sent to the Royal College of Surgeons, and there examined by Dr. Goodhart. Mr. Hutchinson mentioned a second case, and showed a coloured sketch of the section, of lymphadenoma of the liver. The subject of this case was a middle-aged man, who came into the London Hospital with panophthalmitis of both eyes. No cause was assigned for this attack. Both eyes were lost, and became soft. He complained much of a feeling of tightness round his chest, and was said to have recently recovered from pleurisy. After a series of symptoms which it was very difficult to explain, he at length died. The *post mortem* examination, by Dr. Sutton, showed that he was the subject of lymphadenoma of various viscera, the liver affording a splendid specimen of that disease. It was now found that some of the external lymphatic glands were enlarged, but their enlargement had not been sufficient to attract attention during life. There was no proof of new growth in the eyes.

The PRESIDENT said other specimens would be shown at the next meeting. The exhibition had illustrated well the advantage of grouping specimens of like disorders. The present exhibition had elicited some important facts, and had helped to re-establish the distinction between leukaemia and Hodgkin's disease or lymphadenoma. In the former, there was an increase in the white blood-corpuscles; in the latter, there was not, as shown by Dr. Wilks many years ago. (In our last report, by the omission of "not", Dr. Wilks was made to say there was leukaemia in lymphadenoma.) In Dr. Greenfield's thirteen cases, only in one was there an increase in the white blood-corpuscles. In his own seven or eight cases, in none was there an increase of white corpuscles. Secondly, there was no invasion of adjacent tissues by the enlarged glands in splenic leukaemia, as was the case in lymphadenoma. Thirdly, Dr. Gowers had observed that, in a great proportion of cases of splenic leukaemia, malaria was present (in about 25 per cent.), and this coincided with his experience; but there was no such connection in lymphadenoma. It would be important to decide what amount of increase in the white blood-corpuscles constituted leukaemia. Leukaemia was a loose term. In many fevers, there was a slight increase in the number of white blood-corpuscles, and yet the condition could not be called leukaemia. Leukaemia might also occur with but little disease of the spleen, as in certain cases of erysipelas and suppuration. He would also call attention to the febrile paroxysms of intermittent type in lymphadenoma, in which the glands grew rapidly during the pyretic paroxysms, often diminishing somewhat again, but never returning to the size previous to the febrile paroxysm. These observations suggested that the disease of the glands might be of an inflammatory nature; but in the disease known as idiopathic anaemia, where there was no enlargement of the spleen or of the lymphatic glands, similar paroxysms of fever had been observed.

*Idiopathic Anaemia.*—Dr. DICKINSON related the *post mortem* appearances of a case, the clinical details of which were furnished by Sir William Gull, he himself not having seen the patient in life. He was tall and well made; born in 1804. He was left a widower at fifty-six. When fifty-eight, he married again, and his wife had children by him. He was in good health till his sixty-eighth year, when he grew weak and bloodless, with languor, which went on to death. There was no cough or dyspnoea. His heart was feeble, and his pulse firm, 75 to 80 per minute. The liver was not enlarged; the faces were normal, and the urine natural. The temperature was normal. The clinical history was chiefly negative. The muscular power failed, and he died faint. All varieties of food and tonics failed to do good. Sir William Gull had said that there would be found no organic changes unless it might be in the suprarenal capsules. Other views had been taken by other physicians. The necropsy was also negative. The body was very white, like those where death had resulted from hæmorrhage. (It was the caricature of *pallida mors*.) There was a little oedema at the ankles. The body was fat, the fat in the abdomen being an inch thick. The lungs were slightly emphysematous. The heart was flabby, and the muscular tissue soft. The muscular fibrillæ contained drops of oil,

but the striæ were not obliterated. There was cardiac failure. The valves had a little fibroid thickening in them. There was a good deal of omental fat, with fat around the kidneys. The liver was normal, except a globular cyst in front of the left lobe. In the gall-bladder were found four gall-stones, not larger than marbles. The stomach and intestines were natural. The kidneys contained a few cysts, but were otherwise normal. The spleen weighed ten ounces, as a guess. It was diffident. On microscopic examination, the spleen-pulp contained a large number of nucleated cells, with red blood-corpuscles of small size and some hæmatine, not unlike the diffident spleen of febrile conditions. The suprarenal capsules were enlarged in size, but not altered in structure. Together, they weighed four drachms. The absorbent glands were quite natural. He did not see the blood in life. The blood was not leucocythæmic after death; and not more than half a dozen leucocytes could be seen in the field of the microscope. The heart contained some small *post mortem* coagula and bloody fluid. The endocardium was not blood-stained. The only disease was in the blood itself. It was a typical case; but he had seen others he should like to relate, but would not at that late hour.

Sir WILLIAM GULL said he had little to add to what was already known. Light was coming out of chaos now. It was clear that there were conditions not yet investigated. There were three great fields—anaemia, leukaemia, and Hodgkin's disease—on which we had not yet precise knowledge. The blood in leucocythæmia might contain more white corpuscles than red; the red might be some small and some large. We should not be contented with their anatomical characters, but investigate their chemical characters. Were they like the leucocytes in inflammatory affections? What was the quality of these leucocytes? Did they pass into red corpuscles? In leucocythæmia, he thought they did not take that course. Had the white corpuscles any relation to the pus cell which contains pyine? or to the inflammatory cell? The pyrexia was remarkable; it was not high, but it was persistent, and went on from day to day. When the spleen was enlarged in malarial affections, the pyretic attacks ceased. As to the case related by Dr. Dickinson, some said there must be something; yet they could find nothing. It was a purely negative condition, like the anaemia of girls. Iron, good food, all were useless; it was "a blank" onwards. Hodgkin's disease was not, he thought, so common as some of the speakers seemed to think. It was a remarkable malady. In one case, he had seen the enlargement of the glands disappear in twelve hours during a febrile condition. The patient died rapidly; but no enlargement of the glands could be found after death. All true pathology was not to generalise, as his friend Dr. Goodhart had done, but to individualise.

Dr. WILKS said that the subject of anaemia did not quite rest now where Sir William Gull left it six years ago. Anaemia was not the same as leukaemia. The necræmia described by German writers had been confirmed by English observers. There was a death of the blood in some cases.

The PRESIDENT said the first case of leucocythæmia described by the late Dr. J. Hughes Bennett was described as a case of suppuration of the blood.

Dr. ANDREW observed that pernicious anaemia was an aggravated form of anaemia; and in that he agreed with Sir William Gull.

## CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 22ND, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*The Application of Magnets for the Removal or Displacement of Iron and Steel Chips from within the Eye.*—Mr. MACDONALD McHARRY read notes of a case illustrative of such use of magnets. The patient, a man aged 31, came under treatment at the Royal South London Ophthalmic Hospital during July last, for an injury to his left eye, caused by a chip flying from either a steel tool or the hammer with which he was striking the tool. Twenty-four hours after the accident, there was commencing slight iritis; an altered reflex from a portion of the cornea indicated where the steel chip had impinged. Before dilatation of the pupil, no lenticular opacity could be detected, and the ophthalmoscope revealed nothing abnormal in the vitreous. Tension was normal. There was but insignificant tenderness. The eye was far easier than on the night after the accident. Atropine drops, two grains to the ounce, were prescribed. The next day, forty-eight hours after receipt of the injury, the eye was quieter. The pupil was widely dilated. Vision equalled six-twelfths. The corneal surface was almost normal. But there was a fragment of metal upon the anterior surface of the lens, occupying a situation downwards and inwards from its centre, and so placed as to be completely concealed, except when the pupil was widely dilated. The lens was seen to be perfectly transparent, except at the

small area hidden by the chip, which was a long narrow strip. From the position and shape of the chip, Mr. McHardy judged that, if left alone, it was certain sooner or later to gravitate down behind the iris and lead to destructive mischief of one or both eyes; hence, that its removal was imperative. Recognising the possibility of the lens-capsule being wounded by the chip, notwithstanding the continued transparency of the lens, possibly through the chip by its very presence plugging a laceration in the lens-capsule, and thus excluding the aqueous humour; he could not feel sure that the lens-capsule was then so damaged as to necessitate the formation of cataract. He hesitated to subject the eye to the dangers attending the extraction of a transparent lens by the scoop, and was not satisfied that such a measure would insure the removal of the chip. The use of the forceps for removal or dislodgment of the chip was undesirable, as it would almost certainly wound the lens-capsule, and, through occasioning a loss of the aqueous humour, would cancel the mydriatic action of the atropine, so as to conceal the chip from view. To meet the requirements of the case, Mr. McHardy devised a magnetic spatula, which, being inserted through a needle-puncture which it just plugged, would prevent an escape of aqueous humour and the attendant diminution of the pupil, so allowing the foreign body to be manipulated whilst fully in view. Mr. McHardy had preferred a spatula which was an electro-magnet, as he could apply such an one to the chip before calling the attractive force into play; and this power could be interrupted at pleasure, so that any undesirable position of the fragment, with reference to the spatula, might be changed; thus obviating the risk of damage to the lens capsule which would be incurred if the chip were induced to jump across, on the approach of a permanent magnet. Seventy-two hours after the accident, when the condition of the eye was that described on the previous day, his colleague Mr. Rudenell Carter suggested that, before introducing the spatula, it should be tried what, if any, influence a magnet would exert through the cornea upon the chip. Accordingly, Mr. McHardy placed the man in a chair, held before his eye a powerful electric bar magnet, with the result that, when its pole was four inches from the eye, the chip was seen to spring away from the lens to the inner surface of the cornea. On withdrawal of the magnet, the chip fell into the anterior chamber, whence it was evacuated through an ordinary iridectomy incision. As soon as the chip left the lens, it revealed a patch of opacity precisely of its own size; it was, therefore, evident that complete cataract might be anticipated. This followed, and the injured lens underwent absorption without setting up any inflammatory reaction. Atropine was continued during the absorption; and the patient, who was present, had normal distant vision with a lens of twelve dioptries, and read No. 1 of Jäger's types with a lens of fifteen dioptries—the most favourable possible issue to such a case, and one that had been attained without subjecting the eye to any danger other than that directly produced by the entrance of the chip. Mr. McHardy was indebted to Mr. Ladd for the loan of the large magnet, as well as for valuable hints respecting the battery power to be used; and to Mr. Faveaux, of the firm of Messrs. Weiss, for the great, prompt, and faithful pains he had taken in carrying out the suggestions for making the electro-magnetic spatula which was exhibited. In his concluding remarks, Mr. McHardy quoted from a paper by Dr. McKeown in the *Dublin Journal of Medical Science*, who had successfully used magnets for the removal and diagnosis of chips of steel or iron in the vitreous body; he said, that this case had so enlisted his interest in the subject, that he looked forward to carrying out investigations with a view to ascertain the most favourable conditions under which the magnetic power could be applied for these purposes.

Mr. B. CARTER had seen the case, and thought that any other mode of removal would have been dangerous to the eye; whilst, if nothing had been done, there would probably have been destructive inflammation. Any use of forceps would have injured the lens. The use of the magnet had obviated all difficulties.

*On Retinitis Hemorrhagica and its suggested connection with Gout and Venous Thrombosis.*—Mr. JONATHAN HUTCHINSON read a paper upon this subject. He first mentioned the characteristics of the disease known as retinitis hemorrhagica, and said that it must be carefully distinguished from cases of retinal hemorrhage in association with evidences of kidney-disease. The latter were common enough, the former rare. He exhibited three ophthalmoscopic drawings to illustrate the malady, one copied from Jäger's *Atlas*, and two original; and remarked that they showed, as was always the case, innumerable hemorrhages scattered over all parts of the fundus, and all of flame-shape and branching out in lines radiating from the disc. In one they were small, in the other two of considerable size. Amongst other peculiarities of the disease were mentioned the absence of any white deposits such as occur in renal retinitis, the extreme turgescence of the vena centralis, the diminution of the artery, and frequently considerable swelling of

the disc and the adjacent parts. Some statistical facts as to a group of fifteen cases were given. The author thought the disease more common in men than in women, in one eye than in both, often sudden in its onset; and he had been much impressed by the fact that most of those who had been under his care were past middle life, of somewhat plethoric habit, and frequently with definite history of gout. The extreme turgescence of the vein had led him to conjecture that the cause of the disease might not improbably be plugging of the central vein. This hypothesis would account for the sudden onset, the frequency with which one eye only was affected, and the extreme multiplicity of the hemorrhages. He had tried in several cases since this idea had occurred to him, whether stagnation of the blood in the veins could be proved by pressure on the eyeball; and, although in most cases it was certain that the veins did empty somewhat on pressure, yet more than once it had appeared to be almost motionless. He had not had any opportunity of making a dissection. His hypothesis was that, in connection with gouty tendencies, the vein became plugged, and that from this plugging all the other conditions resulted. He had seen several cases of retinitis hemorrhagica in which no definite history of gout could be obtained, but, in almost all, the patients' state of health favoured the supposition that a gouty tendency was present. In a few of the cases, small quantities of albumen were present in the urine; but, as a rule, the cases differed much from those of renal retinitis, and their prognosis was probably somewhat less grave. In no single case had any dropsy been present. The author fully admitted that the group was not one which could be abruptly defined, and that some cases occurred in which the characters were ill-marked, and in which the conditions were mixed with those of renal retinitis. The flame-shaped peculiarity was, no doubt, to be explained by the supposition that the blood was in the innermost or nerve-fibre layer, and there was no doubt that this form was assumed by retinal hemorrhages in many other cases, as, for instance, in optic neuritis from tumours, and in renal cases. In these, also, it was quite possible that thrombosis of branches of the vein might exist. He concluded by asking the experience of members of the Society on the points in question.

Dr. BROADBENT said that retinitis and hemorrhages were by no means limited to one kind of kidney-disease, nor, indeed, a constant feature in any. Certainly, hemorrhages were more common with the contracted kidney; but were they more common in gouty subjects? He would like to know some more definite characters as distinguishing those spoken of from the hemorrhages of cerebral tumours. If due to thrombosis, the causation would be similar to that produced by obstruction in cases of tumour.—Mr. B. CARTER thought that two of the drawings did not correspond. In one, there were obliteration of the disc and flame-shaped hemorrhages; in another, the disc was well defined, and the hemorrhages were round. He thought Mr. Hutchinson's explanation of the shape of these hemorrhages the true one. When they were flat and expanded, they probably lay beneath the membrana limitans. A distinction ought to be made between arterial and venous hemorrhage; the latter was sometimes found in women about the turn of life, and he had seen it in the case of osteitis deformans described by Sir James Paget. He would also like a somewhat more exact definition of gout; a mere history of gout obtained from a patient was too vague to go upon, except there were well marked symptoms of the condition. There was a risk in a too hasty attempt to connect local phenomena with general states.—Mr. HOWARD MARSH alluded to the connection between gout and certain forms of phlebitis as pointed out by Mr. Prescott Hewett and Sir James Paget. In these cases, there were often both a gouty family history and a personal history of the same kind. One of the gouty phenomena described by Mr. Prescott Hewett—namely, plugging of the veins of the corpora cavernosa of the penis—had recently been redescribed in America as a new disease.—Dr. BARLOW had only seen one case of the form of hemorrhagic retinitis described. It was interesting in connection with the other forms of hemorrhage found with gout, as, for example, the hemorrhages occurring into the joints, described by Drs. Hilton Fagge and Pye-Smith. His patient was a young man aged 25, the subject of the hemorrhagic diathesis, and then suffering from renal hemorrhage. When only twenty-one, he developed signs of gout, and when under Dr. Barlow's care he had one of those arthritic attacks, in the course of which the temperature rose to 103 deg. and 104 deg. Fahr. Sir W. Jenner had shown the cause of swelling of the joints of those of the hemorrhagic diathesis to be the effusion of blood or serum. The case showed the connection between gout and the hemorrhagic diathesis.—Mr. HUTCHINSON, in reply, said he was not acquainted with effusions of blood elsewhere in the body in gout. The obstruction of the veins in it he bore in mind. The apparently punctiform ecchymoses, remarked by Mr. Carter, were really linear, but small.

*Cases of Effusion into the Pleural Cavity.*—Dr. W. H. BROADBENT

read notes of three cases. In Case I, a gentleman aged 76, under the care of Mr. Meehan and Dr. Broadbent, unusually vigorous for his years, who had for a few days suffered from dyspnoea after exertion, was found on May 16th, 1877, to have fluid in the right side of the chest up to the level of the nipple; the heart and other lung being sound. Next day, the pleural cavity was nearly full, and on the following day quite full. The patient could not now turn in bed without serious shortness of breath. Under these circumstances, paracentesis was considered to be urgently required; and, after consultation with Sir William Jenner, was performed on May 19th. Eighty ounces of fluid were withdrawn. The fluid had almost the colour of blood, and rapidly deposited a layer of blood-corpuscles nearly an inch thick. Notwithstanding this, the patient made a good recovery, and still remained well. The points worthy of remark in this case were considered to be—1. The age of the patient. Advanced age was taken by Dr. Broadbent as a reason for early operation when the pleural cavity was full of fluid. The patient was then less able to bear a long illness, and the want of elasticity of the structures rendered the pressure-effects more dangerous, and prevented the falling in of surrounding parts during resorption, should the lung fail to expand. 2. The rapid effusion of the fluid, which was unexampled in the experience of the reporter. 3. The large amount of blood, which, with the rapidity of the effusion, was suggestive of malignancy. This, however, might be considered as set aside by the recovery and present good health of the patient. Probably the cause was undue exertion.—Case II. A second illustration of recovery after paracentesis thoracis in advanced life was a case of pleurisy with effusion at the age of 73. The patient, a billiard-maker, was admitted into St. Mary's Hospital on September 24th, 1874, with all the signs of effusion into the left pleural cavity, filling it completely, and displacing the heart. On October 6th, five pints of clear fluid were drawn off; and on the 17th, he left the hospital convalescent. He resumed his occupation, and was well twelve months later, but died in 1876.—Case III. A gentleman aged 24, of a phthisical family, but personally healthy, began to suffer pain in the left side in August 1877; a fortnight later, he was compelled by shortness of breath to give up cricket and violent exercise generally, but he continued to go out up to September 24th, when Mr. Wigmore was called in; and, finding signs of fluid in the left pleural cavity, confined him to his room. On September 28th, the patient was seen by Mr. Wigmore and Dr. Broadbent in consultation, and it was agreed that paracentesis should be performed next day at 4 P.M. There had been no dyspnoea nor other urgent symptom. At 6 A.M., on waking up after a good night, he was suddenly seized with shortness of breath; and, after a struggle of two or three hours, died. A *post mortem* examination could not be obtained; but probably the cause of death was thrombosis in the veins of the compressed lung extending to the heart.

Dr. WHIPHAM referred to a case under the care of Dr. Barnes at St. George's Hospital. The patient had been in hospital a month for ulceration of the os uteri, when she had slight shivering, but nothing to indicate any pleural effusion until two hours before death, when she began to suffer from dyspnoea. He was able to make out the existence of fluid in the left pleura, and this was confirmed after death. No thrombi were found.—Dr. CAYLEY said that Dr. Broadbent's cases showed the dangerous condition of a patient with the chest full of fluid. In the case of a gentleman in this condition, who refused paracentesis, death occurred suddenly.—Dr. SYMES THOMPSON mentioned a case where rapid effusion was successfully treated by tapping.—Mr. MAUNDER said one point of interest in Dr. Broadbent's elderly patient was the origin of the blood; the only explanation offered being the possible presence of malignant disease. Probably this was not the cause, the patient being in good health, and twelve months having elapsed since the operation. He suggested that it might be accounted for as the result of congestion and oozing, from want of tone, in an elderly person, and analogous to the accumulations of blood sometimes met with in the bladders of old men, and from which they often recovered. With regard to tapping in such a case, there probably would be no two opinions upon the propriety of such a step, when a patient's life was in imminent danger from suffocation.—Mr. MARSH referred to a case of sudden death with pleural effusion in dropsy after scarlet fever.—Dr. LEES mentioned a case, spoken of by Dr. Clifford Allbutt, of a young girl suffering from pleuritic effusion, who fell down dead while walking to Addenbrooke's Hospital.—Dr. BROADBENT briefly replied.

#### HARVEIAN SOCIETY OF LONDON.

THURSDAY, APRIL 4TH, 1878.

GRAILY HEWITT, M.D., President, in the Chair.

*Congenital Malplacement of Heart.*—Dr. G. DE G. GRIFFITH showed a girl with this abnormality. She had had rheumatic fever.

There was no transposition of the other viscera.—Mr. GILES said a systolic murmur could be heard, as well as a presystolic murmur, with a thrill accompanying it.

*Gouty Teeth.*—Dr. W. STEWART said that, in consequence of an allusion to gouty teeth by Dr. Fothergill at the last meeting of the Society, he had taken casts of the teeth of eleven gouty patients. They were selected, not on account of their teeth, but on account of their gout and their family history of gout. The casts were exhibited. In all, the teeth were thick and solid, and worn down at the edges.—Dr. FOTHERGILL said these teeth had first been described by the late Dr. Laycock of Edinburgh. In the casts, the teeth presented a generic resemblance that was unmistakable. They were all solid teeth. The wearing down was probably due to the presence of uric acid in the saliva.—Mr. SEWILL said his attention had been drawn to gouty teeth. He should say they were not pathognomonic; but they were sufficiently pronounced to form an aid in diagnosis.—The PRESIDENT said the subject was a very interesting one.

*Early Diagnosis of Stone in the Bladder.*—Mr. TEEVAN read a paper on this subject. On the arrival of a stone in the bladder, it usually soon gave notice of its advent. The larger the stone was permitted to grow, the more trouble it gave in its removal. If treated when small, it could be dealt with satisfactorily. As to the amount of pain produced, a small oxalate of lime calculus would give rise to much pain, while a large smooth stone behind the prostate caused but little suffering. When the stone was small, there was often difficulty in micturition, from the stone plugging the urethral orifice. This was more apt to happen with boys than with men. The amount of pain produced by stone varied with the habits of life. Hunting often elicited early evidence of the presence of stone, and so had saved many a life. The blood passed with stone was by drops at the end of the act of micturition. Changes in the urine itself were of little value diagnostically. In children, incontinence of urine was often present with calculus; here the stone passed into the prostatic portion of the urethra, and the urine trickled past its sides. Such incontinence was of great diagnostic importance. The family history and the patient's history were often of much service. Rarely more than four of the above symptoms were found together in any one case. In stone-cases, there was little complaint at nights; while in prostatic cases the trouble at nights was usually great. Motion aggravated the symptoms and the pain in stone cases, but did not affect stricture-cases. A stiff bolster under the patient's buttocks was useful at the time of sounding. The finger in the rectum, and a short beaked sound, were of service. It was well to stand straight before the patient, and not on one side. By so doing, it was easier to bear in mind the three long prominences of the pelvis, viz., the sacrum and the tuberosities of the ischia.—The PRESIDENT referred to the late Mr. Liston's diagnosis by asking the patient to jump down from a chair. The patient emphatically refused.—Mr. GILES, Dr. STEWART, Mr. CAIRD, and Dr. WILTSHIRE took part in the discussion which followed; after which Mr. TEEVAN replied, and the meeting adjourned.

#### BIRMINGHAM AND MIDLAND COUNTIES BRANCH: PATHOLOGICAL AND CLINICAL SECTION.

FRIDAY, FEBRUARY 22ND, 1878.

JAMES THOMPSON, M.D., in the Chair.

*Tubal Gestation.*—Dr. W. G. LOWE (Burton-on-Trent) showed a specimen, and read notes of the case. On December 6th, 1877, he was called to the wife of an engine-driver, aged 33. She had had three children, the youngest being fifteen months old. He saw her about 5 P.M.; she was lying on a couch and in a state of collapse; she was able to answer questions correctly. She complained of pain in the bowels; it had been very severe at times, but was then less acute. The abdomen was slightly distended; there was no pain on pressure. At twelve o'clock (mid-day), she was quite well, and, about that time, she went to the closet, where, during defecation, she was seized with agonising pain in the abdomen, at the lower part, and, in consequence, fainted. After a time, she rallied and returned to the kitchen, where she was found prostrate, suffering violent paroxysms of pain in the bowels, occurring every few minutes, and accompanied with sickness. Dr. Lowe ordered her stimulants and opium. At 8.30 P.M., she died, not having shown any signs of rallying. Her friends were not aware that she was pregnant. She had menstruated five weeks previously. At the *post mortem* examination, three quarts of blood were found in the abdominal cavity, and large blood-clots in the pelvis. The uterus, which was retroverted, was enlarged; its walls were hypertrophied, and it contained some mucus, but no decidua. About an inch from the uterus, the right Fallopian tube was dilated into a round smooth enlargement of the size of a walnut, looking blue and congested; and

towards its upper part were two small orifices with jagged edges, from which blood issued when the mass was squeezed. On making an incision into this mass, an embryo of the fourth or fifth week was seen floating in the liquor amnii. The walls of the enlargement were much thickened anteriorly, the embryo being attached posteriorly to the tube. The right ovary had in it no corpus luteum, but growing from it was seen a cyst containing clear fluid. The left ovary, which was much larger than the right, contained a corpus luteum.

*Syphilis.*—Mr. BARTLEET, in opening a discussion on syphilis, pointed out that definite knowledge of this disease was of comparatively recent date; and that, while we must feel under great obligations to investigators of syphilis in times past, we must remember that their facts and statistics are not of any present value. Formerly, hard chancre, soft chancre, and gonorrhoea were all spoken of as syphilis. Present syphilographers, while, of course, recognising gonorrhoea as a venereal disease, did not look upon it as in any way syphilitic; and, moreover, considered soft chancre or chancroid as purely a local affection, while syphilis, of which hard chancre was one symptom, was held to be a disease of the system generally. While there were many points of similarity between hard and soft chancre, it must be remembered that like conditions were held between other diseases which are quite distinct. Formerly, scarlatina and rubella, and, more recently, typhus and typhoid fevers, had been respectively held to be varieties or modifications of one disease; and, even now, some looked for constitutional symptoms as a consequence of chancroid: a result which, he believed, never really occurred. Fournier's clear definition of chancroid—"a specific malady consisting in a peculiar ulcer which secretes a virulent auto-inoculable pus; a malady purely local, never giving rise to any symptom which can be referred to a constitutional infection"—could hardly be improved; while typhus was a blood-disease caused by the absorption of a virus, and manifesting itself primarily by the appearance of a sore at the point where the virus entered, and afterwards by a succession of morbid manifestations occurring at longer or shorter intervals, and affecting all or any of the tissues of the body. The typical indurated or Hunterian chancre Mr. Bartleet held to be comparatively rare; and mistakes in the diagnosis of syphilis, and consequently erroneous opinions as to the non-systemic infection of chancroid, were very common. It must be remembered that syphilis or hard chancre was often seen with very limited induration: what had been called parchment-induration, a thin layer strictly limited to the base of the sore. Practically, the points on which the differential diagnosis was founded were these. The time of incubation of chancroid is rarely over a week; of chancre rarely under three weeks. Chancroid is often multiple; chancre is usually unique. Chancroid is always an ulcer, and having undermined edges, like an inverted funnel; chancre is often only an abrasion of an ulcer; it is funnel-shaped. Chancroid is abundantly suppurating; in chancre, there is no suppuration. Chancroid is often accompanied by suppurating bubo; chancre is rarely accompanied by suppurating bubo, always by a chain of enlarged glands. Almost all these symptoms may become less typically distinctive. A chancroid, from irritation, may acquire an oedematous sore simulating induration, and a chancre may be irritated into secreting pus. So also the indolent enlarged glands, in a scrofulous subject of chancre, may suppurate. To add to the difficulties of prognosis, cases occur where individuals have contracted both diseases at the same time, or, at all events, at the same *locale*, presenting first of all a chancroid, coming a few days after contagion, which, three or four weeks later, assumes the appearance of hard chancre, this being due to the different periods of incubation of the two diseases. Mr. Bartleet related two recent cases he had carefully observed of this condition, one of which presented the peculiarity of two indurated chancres: in his experience, a most rare condition. Experimentally, the two diseases could readily be distinguished, chancroid being indefinitely auto-inoculable, while syphilis was invariably not auto-inoculable. This test should, however, rarely be employed, and never without the precaution of immediately destroying the inoculated chancroid. As regards treatment, chancroid usually healed in a few weeks under ordinary hygiene and tonic treatment, combined with local astringents. Iodoform Mr. Bartleet had found most useful, but its pungent odour rendered it somewhat objectionable. Chancroid, if destroyed wholly and entirely by nitric acid, became an ordinary ulcer which readily healed. After recovery, the patient need have no fear of secondaries, but was liable at any time to a fresh infection. Mr. Bartleet believed that mercury was the remedy for syphilis (hard chancre). He usually employed either inunction, or gave small and frequent doses of grey powder; one grain of calomel divided into twelve pills, one each hour, would rapidly bring the patient under the influence of the drug. The slight tenderness of the gums should be kept up, not only until the sore had healed, but until all trace of induration at the site had disappeared; and it was well to continue small

doses of grey powder for some weeks after this. The local condition having been recovered from, the patient would probably never contract a chancre again, because he retained the systemic infection; this might spontaneously pass away after a long time; but Mr. Bartleet believed that the only sign of this recovery was the capability of again contracting a hard chancre. In advanced secondary or tertiary manifestations, gummata of any tissue or organ, Mr. Bartleet advocated iodide of potassium in large doses. Van Buren said there was no limit to the dose, except the production of the effect. Mr. Bartleet mentioned cases: one of gummatus ulceration of the fauces, in which the advance of ulceration was not controlled until six drachms a day of the drug were taken; a case of rupia where seven drachms a day were taken; and a case of syphilitic alopecia where no good result was evident until one ounce a day was taken. Mr. Bartleet commended Van Buren's formula as convenient for measuring the dose of the drug; viz., an ounce of iodide of potassium dissolved in an ounce of water. Each minim represented a grain of the iodide. The drug should be given well diluted, and might often be advantageously combined with carbonate of ammonia or citrate of iron. If iodism resulted, the iodides of sodium and ammonium should be substituted. Mr. Bartleet said, in these advanced cases, he had often found benefit follow the administration for five or six days of green iodide of mercury, in one-grain doses, prior to commencing the iodide of potassium. Mr. Bartleet concluded by saying that he had found good from treating many obscure cases, such as malignant-looking ulceration, as possibly syphilitic before condemning them as malignant, and the patient to operation or to a lingering death.—Mr. THOMAS CHAVASSE, who declared himself a dualist, preferred to apply the term chancre to both kinds of sores, and the term sclerosis to the constitutional affection, as on the Continent.—Mr. PALMER thought that mercury could not be commenced too soon after the diagnosis of syphilis was certain. Syphilis was a destructive disease, and he had seen the soft palate lost by delay in the administration of mercury.—Mr. WATKIN WILLIAMS thought the course which syphilis ran depended greatly on the constitution of the individual.—Dr. THOMPSON agreed with Mr. Bartleet on most points. He referred to a case where symptoms of syphilis had reappeared after fifty years' abeyance, during which time there had been no fresh inoculation.

## SELECTIONS FROM JOURNALS.

## THERAPEUTICS.

**POLYURIA SUCCESSFULLY TREATED BY ERGOT OF RYE.**—The polyuria in a case reported by Dr. Rendu (*France Médicale*, Feb. 27th, 1878) was accompanied by supraorbital neuralgia, vertigo with loss of consciousness, excessive thirst and hunger, with emaciation and loss of strength, although the patient consumed a considerable quantity of food. The urine contained no trace of sugar; the quantity was about ten quarts a day. The urea eliminated by this means in the twenty-four hours amounted to from about 1,250 to 1,400 grains. Before having recourse to ergot of rye, tincture of valerian was first tried for this patient, in the dose first of fifteen minims, and soon afterwards of half a drachm. Under the influence of this treatment, the urine diminished by nearly a quart. Sulphate of atropine, in the dose of one milligramme (.015 grain) at first, then two, daily, produced a similar improvement; but no advantage was found in persevering in this course, since the appetite diminished with the valerian, and the thirst increased with atropine. Ergot of rye was then tried. The success with this agent was remarkable. In eight days, the urine fell to 1,600 grammes and the urea to 15 grammes in the twenty-four hours; the emaciation was stopped; the strength returned; whilst the thirst and the excessive desire of food also disappeared. Dr. A. Costa (*New York Hospital Gazette*, Feb. 15th) reports also a case of diabetes insipidus with the excretion of ten pints of urine daily, with sugar or albumen, marked by great emaciation; and states that he treated the patient with fluid extract of ergot, which treatment had been followed by striking success; i.e., complete cure in two cases in private practice. Dr. A. Costa put the patient upon an initial dose of half a drachm of the fluid extract thrice daily, the dose to be increased gradually, first to one drachm, and then to two drachms. There was at once apparent a great reduction in the quantity of urine passed daily. From ten pints, it fell to six pints daily; then to three, where it remained. Even before reaching the present limit, he ordered the dose to be gradually reduced, first to one drachm, and then to half a drachm. Then it was stopped altogether, and mint-water substituted in its place. For the past two weeks, he had had no ergot, and might be considered permanently cured. The amount of urine daily passed varied between two and three pints.

**GOA POWDER IN SKIN-DISEASES.**—Goa powder has been employed with a certain amount of success by Dr. E. Besnier at the Saint Louis Hospital in Paris. In the treatment of psoriasis, it modifies the surface with rapidity, and seems to accelerate the cure of the eruption more quickly than oil of cade. A glycerole of Goa powder should be rubbed in every day. These frictions have the advantage of being odourless, but are very irritating to the eyelids, and may cause epiphora and redness of the conjunctiva. Friction with this powder has also cured eczema. Dr. H. Blanc, an Indian army surgeon, states that he has found it useful in herpes circinatus; and Dr. Champeaux, in a paper published in the *Archives de Médecine Navale*, comes to the conclusion that it is an antihyperæmic.

**USE OF THYMOL AS AN ANTISEPTIC.**—Dr. H. Ranke of Halle, in an article in Volkmann's *Sammlung Klinischer Vorträge*, says that thymol was first used by Paquet of Lille as an antiseptic in foul suppurating sores and (by inhalation) in pulmonary gangrene, with good effect. Experiments have shown that its poisonous power on the organism is only one-tenth that of carbolic acid, and may practically be left out of account. Dr. Ranke uses the following solution: thymol, 1 part; alcohol, 10 parts; glycerine, 20 parts; water, 1,000 parts. This solution does not act on the instruments, nor the spray on the respiratory organs; it produces some burning of the skin at first, but no anaesthesia. A useful dressing is made of 1,000 parts of gauze, 500 of spermaceti, 50 of resin, and 16 of thymol. This gauze remains constantly moist, and is not irritating. If the dressing be covered with gutta percha, the smell of thymol is still perceived at the end of eight days. Dr. Ranke has used the thymol dressing in fifty-nine cases, with excellent results. Among them were four cases of amputation of the breast with clearing of the axilla, and three cases of extirpation of tumours from the breast. He says that, under the action of thymol, healing takes place sooner, the discharge from the wound is less, and the cost is less, than with carbolic acid. Dr. Fritsch (*Centralblatt für Gynäkologie*, No. 6) believes that thymol is also of great value in obstetric practice. It removes the smell from the hands in cases of putrid abortion, carcinoma uteri, etc., more quickly than any other agent, and produces no irritation. There must always be

some hesitation in entrusting midwives with carbolic acid; but thymol may be safely given to them without fear of unpleasant consequences. The solution above mentioned is likely to be specially useful for permanent irrigation, for the dressing of chronic suppurating exudations, for washing out abscess cavities in the female genitals and in the breast, and for injections into the uterus.

**HYPODERMIC INJECTIONS OF DIGITALINE.**—At a recent meeting of the Paris Société de Thérapeutique, M. Gubler announced that, after having made many attempts to utilise the active principles of digitalis in subcutaneous injections, he believes that he has attained his object. He uses a solution containing 0.2 per cent. of Homolle and Quevenne's amorphous digitaline in equal parts of water and alcohol. One gramme of this solution contains two milligrammes of digitaline. He injects half of the contents of the syringe; that is to say, one milligramme of digitaline, and obtains all the effects of digitalis. These injections do not bring on any local accidents.

## OPHTHALMOLOGY.

**HYSTERICAL DISORDER OF THE EYES.**—Dr. Schenk (*Prager Med. Wochenschrift*, Nos. 18 and 19, 1877) says that the disorders of the uterus and ovaries which give rise to hysteria may cause, by reflex action, an increased irritability of the sensory nerves of the apparatus of accommodation. At first after long exercise of the eyes, and subsequently after using them for a minute, pain is felt in and about the eyes: it differs from true neuralgia in having no typical course, and in being prevented by avoiding exertion of the eyes. Both eyes are generally affected, the right most so—in forty-six cases out of sixty observed. Depressing affections and moisture, as well as the duration of menstruation, increase the severity of the pains; during pregnancy, they are less. Vision of distant objects is not impaired. The state of refraction has no influence on the development of the malady; the extent of accommodation is unchanged; the ophthalmoscope detects nothing abnormal. In some patients, photophobia, photopsia, *malaise*, vomiting, vertigo, and even convulsions, are met with. The course of the disorder is very tedious: it ceases with the commencement of the climacteric period. Married women are most frequently attacked; even robust apparently blooming women are not exempt. It very rarely occurs in anemic nervous men. The treatment consists in rest of the eyes, the use of moderately convex glasses, and, in cases of photopsia, smoke-coloured glasses. Castor, valerian, acetate of zinc, and atropine drops, are useless; in some cases, severe pain has been relieved by large doses of quinine.

## OBSTETRICS.

**INJECTION OF ERGOTIN IN POST PARTUM HÆMORRHAGE.**—M. St. Philippe relates (*Gazette Médicale de Bordeaux*, Jan. 1878) a case of excessive hæmorrhage consequent on faulty insertion of the placenta. Ergot administered by the mouth was ineffectual. He then injected ergotin under the skin, employing Moutard-Martin's solution, which contains one part of ergotin to six of water and six of glycerine. He injected an ordinary subcutaneous syringe under the skin of the arm. The effect was instantaneous; scarcely a minute afterwards, the uterus firmly contracted, the hæmorrhage ceased, and the patient did well. There was a little œdema round the wound, but no inflammation. M. Chantreuil reports also (*Journal de Thérapeutique*, Feb. 25th, 1878) a case of excessive metrorrhagia preceding labour, and succeeding it after the application of forceps, with syncope and uncontracted uterus. In this case, M. Chantreuil injected, at short intervals, four small subcutaneous syringes of a solution of equal parts of Bonjean's soft ergotin and distilled water. Some of the solution was lost. He estimates altogether the quantity of ergotine injected at 21½ grains. At the end of half an hour, the uterus contracted, and remained firm all night. To counteract the acute anæmia to which such patients often succumb twelve or fifteen hours after delivery, he injected four times a syringe of ether under the skin, and gave other similar injections of brandy during the night. Under this influence, the patient revived and warmth returned. As the stomach would not tolerate anything for days, rectal injections of beef-tea, milk, and wine and water, were employed. A blister was applied over the stomach, which tended to restore its tolerance of food; and the patient recovered. Dr. Chantreuil employed, with the same success, injections of ether in four other cases of hæmorrhage, of which two were after abortion and two after accouchement. In all four, the state of the patients was so alarming that transfusion had to be considered. Hypodermic injections of ether, which do not offer the dangers of transfusion, which are easy to practise and require no preparation, appear to Dr. Chantreuil as efficacious as transfusion itself.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, APRIL 13TH, 1878.

MEDICAL REFORM.

IN our last issue, under the above heading, we referred to the present Medical Bill of the Government as utterly inadequate to the needs of the public and the legitimate demands of the profession. It neither establishes uniformity in qualification on the plan of equal fees and equal examination in each division of the kingdom, nor does it concede any representation on the General Medical Council to the profession as a body distinct from the universities and corporations. In order to establish our right to speak authoritatively on the subject of medical reform, it may, perhaps, be well to place beyond controversy the part played by the Association in securing the Medical Act of 1858; for it sometimes strangely happens that the opponents of a measure beforehand hail it as in a great degree their own handiwork when once it is accomplished, just as a sovereign greedy of military glory may, through constant dwelling on the events of a campaign, work himself into the unquestioning delusion that he played an important personal part by his presence in the last decisive battle.

The Association is now in the forty-sixth year of its existence. It is not too much to say that, at the date of its formation, the profession was a chaotic mass of *disjecta membra*. The founders of the Association sought to weld this disjointed profession together, to elevate its members by enlarging their attainments, to teach them to acquire self-respect by deserving it, and to stimulate the provincial man to assert his inborn dignity, and to earn ennobling distinction by the example of the illustrious Jenner, who, in the obscurity of a provincial practice, became one of the greatest benefactors of humanity. To elevate the profession as a whole, changes in the way of reform were indispensable. From the second year of its existence, therefore, the question of medical reform constantly occupied the attention of the Association, and, by continued agitation, public interest was at length excited. Mr. Hawes, Sir James Graham, the late Mr. Wakley, and many others, attempted legislation, but in vain; and thus for years matters remained, with every conceivable qualification to practise the profession, from that granted by the Archbishop of Canterbury to that bestowed for a small fee by the Apothecaries' Hall of Ireland. The activity of the Association, however, never flagged: defeated often, discouraged never, it continued to press on the legislature and on successive governments the need for reform, and responded by renewed efforts to those ministers who, after grappling with the subject, abandoned it in despair, with the taunt that they would again attempt legislation when the profession was unanimous in its views.

This was the condition of things when a powerful deputation of the Association, supported by numerous members of Parliament of all shades of opinion, including Mr. Headlam, waited on Lord Palmerston on March 18th, 1853, to ask his support of a Bill drafted by the Association.

Sir Charles Hastings, speaking for the Association, then stated that "they (the Association) had from the first laid down broad principles of medical reform, and had never swerved from them. They were:

1. Uniformity of qualification; 2. Equal rights to practise throughout the United Kingdom; and 3. The adoption of the representative principle in the formation of the councils or other governing bodies. The Bill embraced the establishment of a medical council, of a board of examiners before whom every candidate for the right to practise must go, and of a system of registration."

Strange as it may now seem, the governing bodies of the Royal College of Physicians and of the Royal College of Surgeons of Edinburgh, in the persons of Dr. Renton and Dr. Combe, the respective secretaries, supported the Bill, and thereby committed themselves to the plan of one conjoint board of examiners. As proof of the earnestness of the Association in the cause, it may here be mentioned that, in the year 1852, with an exchequer not, as now, overflowing with funds, but showing more liabilities than assets, £200 was granted to the Medical Reform Committee on March 2nd, 1854. The Association called a meeting in London, when again the four great principles of reform were laid: 1. Uniformity of qualification; 2. Reciprocity of rights to practise; 3. Registration of qualified practitioners; 4. The governance of the profession by representative councils.

It was then sought to place eight representatives of the profession in the Council: four for England, two for Ireland, two for Scotland. In May 1855, a deputation from the Association waited on Sir George Grey, then Home Secretary, from whom they gained no encouragement. It was then arranged that the Bill should be specially confided to Mr. Headlam as a private member, with the names of Mr. Brady and Mr. Craufurd on the back of it. Other Bills were from time to time brought forward; several were before the House at the same time; Lord Elcho's Bill was supposed to be favoured by the Government, when Mr. Headlam, acting for this Association, surprised the Commons on July 1st, 1857, by carrying the second reading of his Bill by a majority of one hundred and forty-seven—the numbers for being two hundred and twenty-five against seventy-eight—a warning to all close corporations of the power to be wielded by the British Medical Association. This vote led to the Government of the day undertaking legislation; there was then no Medical Council in being, and it was to the Association that the Government applied. Mr. Cowper-Temple wrote to Sir Charles Hastings, the President of the Council of the Association, informing him that the Government intended to introduce a Bill the next session, and requesting a personal interview with him before deciding on a plan. This letter was read at the meeting of the Association in Nottingham on July 30th, 1857.

In 1858, the Medical Act passed. The foregoing narrative makes it tolerably clear that there would scarcely have been any Medical Act in 1858 but for the untiring labours of the Association.

When the action of the Association was thus recognised by the Government, it numbered about two thousand members; it now numbers considerably over seven thousand. Mr. Cowper-Temple, in debate the following year, regarded the Association as representing the profession throughout the country. With how much greater force may that be maintained now!

In 1858, the Medical Act passed. In the debate, Mr. Walpole stated "that the rivalry between the Colleges in conferring degrees led to nominal or worse than nominal examinations". These Colleges, through their representatives, exercise a preponderating influence in the General Medical Council. The rivalry for candidates still exists amongst them.

During the negotiations preceding the passing of the Act of 1858, the Medical Reform Committee of that day, in its conferences with the Government, contended for the necessity for a representation of the profession. Mr. Southam of Manchester, Mr. Nunneley of Leeds, members of that Committee, and Mr. Headlam, have stated this. The proposition was deferred until there should be a register formed of the members of the profession, when it was understood that the claims of

the profession in that respect would be granted. From that time to the present, the demand has been disregarded, though different members of the General Medical Council have expressed themselves in favour of it.

In the year 1866, when the Government and the General Medical Council were exchanging communications as to the reform of the Medical Act of 1858, the Association, at the annual meeting in Dublin in 1867, passed an almost unanimous (two dissentients only) resolution in favour of giving representatives to the profession in the proportion of one-fourth of the members of the Council. A deputation from the Association waited on the General Medical Council and requested their adhesion to the proposition. A discussion ensued, evincing divided opinion, eliciting a general opinion that the composition of the Council required modification; but the question was shelved, it was not negated. Year after year, at its annual general meetings, the Association has reiterated the demand for direct representation.

In May 1870, a special general meeting was held in London, when the general principles of reform were laid down to be—

1. Representation of the profession in the General Medical Council;
2. The establishment of a uniform conjoint scheme of examination, to be made compulsory for the kingdom.

In that year (1870), the Medical Bill promoted by the Marquis of Ripon was, as his lordship stated recently in the House of Lords, withdrawn through the opposition of the Association owing to the omission of clauses to effect the desired modification of the Council. The present Chairman of the Medical Reform Committee was then Chairman of the Direct Representation Committee. The late Mr. Graves of Liverpool was a strenuous supporter of the Committee on that occasion. He had previously called a general meeting of the profession in and around Liverpool, and ascertained that it was unanimous in its demand for direct representation in the General Medical Council. He himself brought in a Bill to effect it. Dr. Lush, M.P. for Salisbury, also called the profession in that locality together, and ascertained the existence of the one opinion only. Dr. Lush said it was the only question on which he had ever known the profession unanimous.

When the Government Bill was down for the second reading in the House of Commons, in one short week, during which it was adjourned, upwards of ten thousand members of the profession poured in petitions praying that no measure of medical reform should be passed which did not concede direct representation of the profession in the General Medical Council; and the Committee, acting in obedience to this demand, drafted amendments to that end, when the Bill ultimately was withdrawn. Mr. Forster, on behalf of the Government, then made an offer to the Committee to grant a Special Committee to investigate the composition of the Medical Council in the ensuing session, if the opposition of the Association were withdrawn; but the Committee, having been at that time specially appointed to obtain direct representation in the General Medical Council, were not in a position to accept the arrangement, which was, therefore, declined. The Government Bill was then withdrawn.

In 1873, the Committee, having been merged in a Medical Reform Committee, drafted a Bill in conjunction with Mr. Headlam, to whom the whole question of medical reform was peculiarly familiar. That Bill provides for the compulsory formation of a conjoint board of examination in each division of the kingdom. The Bill of the Government, while approving of the efforts of the English authorities to combine in one board for examination, leaves it optional for two or more of the authorities in Scotland and Ireland to do so: a condition which must prove fatal to the English authorities, which have for six long years toiled to effect conjunction, in the hope—it is to be too much feared, the vain hope—that the authorities in the sister countries would do likewise. Should this Bill be passed, there is great probability

that what Mr. Walpole said in 1858 will be justified in 1878, "That the rivalry between the Colleges in conferring degrees will still continue to maintain competition for candidates". On this ground alone the Bill of the Government must be opposed. The question of direct representation will be again considered.

#### COUNTY GOVERNMENT BILL.

THE County Government Bill recently introduced into the House of Commons is a remarkable document. Without preface, it plunges at once into the whole subject of the administration of county business, recognising the division of all the functions of the Court of Quarter Sessions as capable of being separated into judicial and administrative. The former, including all matters coming before the Quarter Sessions of a county in a judicial capacity, or relating to prisons or police, remains unchanged; and for administrative business, while it is still the Court of Quarter Sessions who have to transact it, a county board is instituted, which becomes the court for that purpose. This county board is to consist of two justices to be chosen, and two elective members to be elected for each petty sessional division of the county. Besides these members, if there be any boroughs wholly situate within the county having a separate commission of the peace, but not a separate Court of Quarter Sessions, and with a population of at least twenty thousand persons, then such borough is to return four members. The two justices are to be chosen by the justices in Quarter Sessions assembled out of the petty sessional divisions; the elective members of the board by the board of guardians of the several parishes situate in the petty sessional division; and the members to represent the borough by the town council. All these elections are to be for one year. It is difficult to understand, for the first time, a petty sessional division of a county—a division the boundaries of which may at any time be changed, and which as a fact are frequently changed—should be chosen for the first time as an electoral area. It represents nothing but a petty sessional division, and, so far as we know, has nothing to recommend it, except that it exists. But these divisions not only exist, but they avoid the difficulty of touching county boundaries. The only reason for adopting the unions as the area of rural sanitary districts in 1872 was a similar one. They were then ready to hand; the boards of guardians representing them, however unfit to have thrust upon them onerous sanitary duties, were already constituted, and thus the trouble was saved of reconstituting the sanitary government of the country on an uniform plan which, while it was acknowledged to be the right thing, would entail much inquiry and necessitate considerable reconstitution of boundaries and districts to make it consistent. This the government of the day were not prepared to undertake, and so we have to-day the anomalies of districts cutting districts and parishes overlapping counties, which has led to this attempted imposition of another anomalous body, to be constituted only to be destroyed when some one shall appear, willing and competent to take the necessary trouble for dealing adequately and satisfactorily with this confessedly difficult subject.

We have always and constantly urged that the reconstitution of districts and areas was at the very root of any satisfactory scheme for local government. That such reconstitution is necessary is shown from the fact that, although the union was adopted as the unit of area in the formation of rural sanitary districts, this unit, which logically should have been the one now adopted, is not only passed over, but, when suggested, is vehemently opposed by the Government. The formation of a county board as an intermediate authority, and one for the consideration and, if necessary, for the execution of joint works, and for the maintenance of joint institutions, has been always considered as the necessary outcome and inevitable necessity of local sanitary authorities: but these considerations have been entirely ignored in the present scheme of the Government, and sanitary districts as such are entirely passed by. Nor is the reason far to seek. In the various parishes of England and Wales, there are 179 unions which overlap the

boundaries of counties, with 3,147,772 acres, and a population of 1,053,423 persons. For registration purposes, these overlappings have been destroyed partially by making the returns of births and deaths correspond with union boundaries; but, for local government, an exactly opposite course must be pursued. It does not follow that this is to be an uniform process; for many of the unions which overlap are entirely rural, and it may be desirable to add the overlapping portion to the adjoining union in the next county, making all government the same within the same area, instead of the chance-medley system which now prevails. Where, however, an urban sanitary authority overlaps a county boundary, then, in almost every case, it would be necessary not only to extend the county up to, but even beyond the boundaries of the sanitary district, in order to include those parts of the county adjacent to large towns, but without their jurisdiction, which have largely grown up without proper supervision and restriction. This has been done to escape the incidence of rating; and now, when, from sanitary and other considerations, boroughs promote Bills in Parliament to extend their boundaries, so that these extra portions should be taken in, they are met by the most determined opposition on the part of ratepayers, manufacturers, and owners: an opposition in almost every case successful. To rectify boundaries is the one elementary condition of improvement in local administration, and it is the one thing which the Bill most sedulously omits. A Bill may provide machinery for this purpose; but this fundamental change in a present anomalous condition can only be effected by a commission appointed to inquire and report on the rectification of boundaries, so that unions, if such are in the future to be maintained, should be, however many there may be in a county, in the aggregate exactly co-extensive with the boundaries of the county, riding, or division of a county. Without this, the present confusion must be sanctioned and perpetrated. It is evident that, in the present Bill, sanitary districts and authorities as such are entirely ignored. We agree that there are too many; that the country has been already cut up into these lesser lights for the purpose of producing darkness; but this has been done by former legislation, and cannot now be ignored. Besides this, proper legislation at this time should tend to the remedying of these antecedently created evils.

But the real key to the consideration of this measure is to determine what is really the object intended to be accomplished. Is the present system of administering the affairs of the country considered deficient in ability or economy? The preamble is silent on this point, and we have heard no real answer to this puzzling question. Is it intended that those who spend money should represent the persons who pay the rates furnishing the funds expended? If so, does the present proposed machinery attain that object? If it do, it is by a very indirect and unsatisfactory method. All that can be said is, that the proposal dilutes the present county authority both in position and ability. It makes the landlord and the tenant for the nonce equal, and the farmer and the landowner sit down at the same table, both equally representing the county, or both equally wanting in representative power. There is, in fact, no backbone to the Bill, and nothing of reform underlying it. It weakens what exists without in any way improving it. It destroys the aristocratic, and, so far as we know, hitherto unimpeachable, and in its place substitutes what is neither democratic or representative. The form is altered in its power for good, and the matter remains the same, without suggested amendment, and with a probability of the good being weakened in the old system, without any corresponding probability of removal of evils. The whole scheme, so far as we can comprehend it, has no *raison d'être*. And, if this be all a county board is to ensure, we had better bear the evils that we know than fly to others the extent of which we can never forecast or appreciate.

The new powers to be granted to the new board are meagre in the extreme. The present administrative purposes carried out by the justices in Quarter Sessions assembled, other than those appertaining to prisons and police, are those connected with the militia, county bridges, shire halls, lunatic asylums, and other county buildings; also

the application of the District Highways Acts, 1862 and 1864, under the powers of which eight thousand or more rural parishes have been united into above four hundred highway districts, maintaining nearly seventy thousand miles of road at about £950,000 a year, or a little more than £14 a mile.

By the Bill, powers are proposed to be conferred by which any roads which are now or may hereafter be distumpiked shall become *main* roads, and are to be repaired by contributions from areas joined together for the purpose, to which, under certain circumstances, the county board may contribute. Media of communication between great towns may be declared to be main roads, and may be repaired, as before stated; or a main road may be reconverted into a simple highway by the order of the county board. Then comes the extraordinary proposal to recur to the wasteful and harassing plan of having toll-gates erected on roads which are cut up by traffic, in order to meet the difficulty of imperial traffic not belonging to the district causing abnormal expense in repairs: a proposal which cannot be supported, and one of a most retrograde character, and which for five years is to continue to be a source of expense and annoyance to all using such road. For these and similar purposes connected with the repairs of main roads, a county road fund is to be created, to be collected by the areas which are to be joined for the purpose, and which are to be taxed in proportion to their rateable value. Such sums are to be paid by the various highway authorities upon the receipt of a precept from the county board; and, in the result, this money is to be equally contributed by the owners and occupiers of property within the highway districts. There is also power given to the county board to enforce the discharge of their duties by defaulting highway authorities within the county, and they may indict any highway authority at the assizes, in order to try the liability of any defaulting authority to repair any highways. For carrying out the purposes of the Rivers Pollution Prevention Act, 1876, the county board is to be made a sanitary authority so far as any streams within or passing through the county are concerned; and, for this purpose, the county is to be considered their district. They may also become conservators of rivers, and they may join with other counties in a scheme for removing obstructions, improving outfalls, dredging, scouring, and cleansing the beds of rivers, and improving the flow of water, and for constructing embankments, etc.; but this permissive power is, as it appears to us, valueless from a sanitary point of view, and the momentous issues of adequate and pure water-supply to districts can never be solved unless and until the appointment of a watershed area authority be determined on in every county or combination of counties, as the physical conformation of the county may require. So long as the water-supply of the county is allowed to be treated in the haphazard way which has prevailed in the past, so long shall we still have to deplore the sad condition of hundreds of parishes in England which are at the present time doomed to drink liquid sewage. The recent evidence of medical and other scientific experts in the case of the Nottingham Water Bill before Parliament showed that, while a most abundant source of exquisitely pure water was at the feet of the inhabitants of an area of some thousands of acres in the villages immediately surrounding the town of Nottingham, more than thirty thousand people were condemned to drink from a scanty supply of water, so-called, which was proved to be nothing less than liquid abomination. Can we wonder at sickness and death-rates continuing high when such things are permitted to go on unchecked and unprovided for? It is in this aspect we feel the greatest disappointment with the proposal of the Government, inasmuch as it clearly shows that no comprehensive view has been taken of the subject; and that there is no real apprehension in the minds of our statesmen as to the real wants which should be supplied by a measure for more effective county administration.

The new board, further, may frame schemes in order to provide asylums for imbecile or insane poor, and schools for training "idiotic young persons being paupers"; and they may prepare schemes for readjusting areas, and present them to the Local Government Board, and

thus, in a questionable way, they may suggest plans for carrying out the provisions of the Public Health Act, 1875, and the Divided Parishes and Poor-law Amendment Act, 1876. Those who live on to or in the next century may possibly have the gratification of seeing something effected under these cumbersome and, up to the present time, effete provisions. For registration purposes, all here so dimly shadowed out has been accomplished by earnest men at the head of a department of the state, and proper machinery, if Parliament really set itself to the task, would, in eighteen months from this date, bring our chaos of boundaries into a consistent whole for all purposes of local government. It is said that the proposal to map out the whole of England like a chess-board with uniform authorities and powers may be very philosophical, but it is impracticable. Those who have given the greatest consideration to the subject have arrived at an opposite conclusion, and maintain, and, we think rightly, that, in order to secure the greatest economy with the highest efficiency, all matters of local government should be administered by one authority with districts arranged according to the exigency of drainage, water-supply, and other local circumstances connected with administration. As a necessary complement to this is the creation of a county or other board for joint purposes common to all the districts embraced within its area. These purposes, as we have already pointed out, are altogether ignored by the present Bill. The remaining provisions of the Bill relate to the appointment of coroners by the county board: a proposal recently enunciated by one of our correspondents. Powers are given to borrow and with respect to the obtaining of provisional order. The remaining supplemental provisions of the Bill merely refer to matters regulating the election of members and the transaction of business of the county board.

WE understand that the friends of the Rev. Mr. Dodwell, acting upon the report of Dr. L. S. Forbes Winslow and Dr. J. M. Winn to the Home Secretary, of which we have already published the substance, propose to apply for a writ of error to bring Mr. Dodwell up to the Court of Queen's Bench for argument of his case.

M. A. GUÉRIN, senior surgeon to the Hôtel-Dieu, was last week in London, and spent several days in studying the methods of dressing wounds employed by Professor Lister at King's College and Mr. Callender at St. Bartholomew's. M. Guérin is well known in this country and elsewhere as the author of the cotton-wool dressing, by which means he protects his wounds from the action of floating germs in the air by the filtrating process furnished by the thick casing of cotton-wool with which he surrounds them. M. Guérin put up a case at St. Bartholomew's Hospital, employing about five pounds in weight of cotton-wool and upwards of a hundred yards of bandage for the purpose. M. Guérin affirms that he obtains excellent results by this method and antiseptic occlusion, which is, however, obviously inferior in certainty to the method of Mr. Lister, and is alleged by those surgeons in France who have employed it to give very imperfect and unreliable results, very different from those which M. Guérin alleges that he obtains from it.

ON Friday, at the Great Northern Hospital, a case of aggravated genu valgum was, at the request of Mr. John Gay and Mr. William Adams, operated on by M. Guérin by the method of forcible straitening introduced by M. Delore of Lyons, and practised since with much success by French surgeons. The patient was a girl aged 15, in whom the deformity in the right leg was very aggravated, interfering greatly with progression, and the procedure is very successful.

THE retiring members of the Council of the Royal College of Surgeons of England at the next election in July are Messrs. Barnard Holt, Henry Lee, and Erasmus Wilson. We have mentioned the probability of Mr. Lund being brought forward; and the names of Sir Henry Thompson, Mr. Callender, and Mr. Lister are also mentioned.

WE understand that notice of motion has been handed in to the Council of the Royal College of Surgeons of Ireland to amend the by-law affecting the practical teaching of physiology, of the application of which Dr. Reuben Harvey last week complained as being injurious to the progress of complete scientific teaching of that branch of knowledge in the medical schools of Dublin.

THE subject of Diseases of the Lymphatic System will be resumed at the Pathological Society of London at its meeting on Tuesday, April 16th, when the discussion will be concluded.

WE are requested to state that Mr. Anderson Critchett is not, and never has been, a candidate for the office of Ophthalmic Surgeon to St. Thomas's Hospital.

MR. WALTER PYE, late House-Surgeon at St. Bartholomew's Hospital, Lecturer on Physiology at St. Mary's Hospital, and Anatomical Assistant in the Museum of the Royal College of Surgeons, has been elected Assistant-Surgeon at St. Mary's Hospital.

A SAD death is reported of Surgeon W. C. Fergusson, B.A., M.D., who managed to escape the observation of his attendants while returning home, in a state of mental alienation, and, getting out of the port of his cabin, jumped overboard unobserved.

As the result of the recommendations of the Scottish Universities Commission, it is considered probable that the valuable collection of coins and medals in the Hunterian Museum of the Glasgow University will be sold in order to provide funds for the maintenance of the museum, for which there is at present no fund specially applicable. The coins are said to have been collected by Dr. William Hunter at a cost of upwards of £22,000, and it is believed that if sold they would realise a much larger sum. At present, they are not used in teaching, and probably not half-a-dozen people in Glasgow have ever seen them, as they are kept in a cabinet with three doors, of which the keys are in a sealed box, and it is only opened in the presence of three of the professors.

PROFESSOR YOUNG reports that the library of the University of Glasgow includes a very large collection of medical books, especially of early medical literature, and a collection of classical books which is described as being perhaps the finest in this country outside the British Museum and the Bodleian. Among them are thirteen books of Caxton's printing and a good many of Pynson and Wynkyn de Worde, and a German poem on vellum with wood-engravings by Albert Dürer. There is some talk of selling even these literary treasures. There are in the library four or five thousand duplicate volumes which might be sold without injuring the literary value of the collection.

#### TESTIMONIAL TO MR. JOHN SIMON.

ON Saturday last, the subscribers to the testimonial of a bust in marble to Mr. John Simon, C.B., F.R.S., late Medical Officer to the Privy Council, in recognition of his eminent services in sanitary science, met at the rooms of the Social Science Association, for the purpose of a private view of the bust, which has been executed by Mr. Thomas Woolner, R.A., and is for presentation to the Royal College of Surgeons. Sir James Paget occupied the chair, and spoke in eulogistic terms of the high character and reputation of Mr. Simon, and the great personal esteem in which he was held by the medical profession generally. Sir William Gull moved the adoption of the report of the General Committee, which thanked the donors for their contributions, and stated that the required amount had been subscribed. The thanks of the meeting were given to the General and Executive Committees, and to Dr. Farr as treasurer, and Mr. Haviland as secretary, for their services. Among those present were Dr. Russell Reynolds, Dr. Owen Rees, Dr. George Johnson, Mr. T. B. Curling, Mr. John Wood, Dr. Waller Lewis, Dr. Iliff, Dr. Hardwicke, Mr. John Gay, Mr. Farrier, Mr. Jacob, etc.

## YELLOW FEVER IN BELGRAVIA.

FOR the first time, probably, in the memory of any living physician, a case of yellow fever ending fatally is reported in London. It occurred in one of the squares in Belgravia. The case was seen before death, in consultation, by Dr. Murchison; and both the symptoms before death and the anatomical conditions after death clearly establish the nature of the case. It was contracted on board a West Indian steamer in which several deaths had occurred. Under some circumstances and during periods of great heats, such an announcement might have created serious alarm; but, with the present temperature, and considering the precautions taken, there is no reason to consider it possible that any local extension of the disease should follow.

## GALLANT CONDUCT OF A SURGEON.

ON the 5th instant, Mr. George Warner Bell, a young surgeon who has been in the Royal Naval Service only a few weeks, was walking on the sea-wall at Haslar Hospital, when his attention was called to an object in the water forty or fifty yards from the shore. This he thought to be a body from the unfortunate *Eurydice*. He was assured, however, that movements had been seen and cries heard coming from this spot by others who were present. Mr. Bell at once stripped and swam out, and by great exertion brought the body within ten yards of the shore, when, by reason of the cold and exhaustion consequent on his efforts, he was obliged, for the preservation of his own life, to quit the body and make his way to the shore. The lifeless body was that of Captain Charles Gray Jones, a patient at the hospital at Haslar; but there is no evidence as to how he came in the water. To the verdict of the jury who sat upon the inquisition which was held upon the remains of Captain Jones, was appended a rider in which the jury desired to record their "admiration of the gallant conduct of Mr. Bell".

## REPORT OF THE LUNACY COMMISSION.

THE select Committee of the House of Commons on Lunacy Law have arrived at a conclusion which might have been anticipated beforehand, that the allegations of *malu fides* and serious abuse in respect to detention of lunatics are without foundation. They recommend further precautions against possible abuse, of the value of which we shall have something to say presently; but they are not of a very urgent or important character. The most useful suggestion they make is one for facilitating the admission into licensed houses of persons such as dipsomaniacs who are not actually under certificate. Altogether, the mountain which has travelled has brought forth a mouse. The cases of grievance put before the Commissioners at great length turned out to be moonshine, and under such circumstances no really valuable result could be expected. A great deal of time has been wasted, for which the only compensation we can see is, that the public mind may possibly be reassured from the scare which first assumed important dimensions under the skilful manipulation of Mr. Charles Reade, in his well known romance "Hard Cash".

## CONFLICTING EVIDENCE.

MR. JUSTICE LINDLEY and a common jury were occupied for three days last week in an action for damages, *Fellows v. Jeffrey and Lewis*, for injuries sustained by plaintiff, a schoolmaster, from a sack of oats falling on him from a crane. The evidence of the plaintiff in every particular was traversed by that of the defendants, the negligence being denied, and the extent of the injuries, represented by Dr. Broadbent and Dr. Bastian, on Saturday, as irremediable and the result of mechanical accident, being asserted by Mr. Smith of King's College Hospital, and by Mr. Erichsen, to be such as could be recovered from in twelve months, and to be the result of organic brain-disease, not of violence. The learned judge, directing the jury that the defendants, under the circumstances of this case, were not responsible for such accidents as their use of their crane in such a place might cause, apart from negligence on their part, and that, if they had used it with reasonable care, they were not to be held as insurers of the safety of all

passers under, concisely summarised and criticised the conflicting evidence, and left to the jury—1. Were the plaintiff's symptoms caused by injuries the result of defendants' negligence? 2. Did the plaintiff contribute to the result by his own negligence? After retiring, the jury found for the plaintiff—damages, £1,250.

## THE GOVERNMENT RESEARCH FUND.

AMONGST the list of grants to be paid from the Government Fund of £4,000 on the recommendation of the Royal Society, during the present year, in aid of scientific research, are the following: Dr. O. J. Lodge—For Investigations into the Effect of Light on the Residual Charge of Dielectrics; on the Conductivity of Hot Glass, and other Transparent Conductors; on Electrolytic Conduction, and other subjects, £100; Dr. W. A. Brailey—For Researches on the Causes determining the Tension of the Globe of the Eye in Man and Animals, and on the Physiological Influence on this Tension of such Substances as Atropia, Daturin, Eserine, and Pilocarpine, £25; Mr. E. A. Schäfer—For Payment of an Assistant in Continuing his Histological and Embryological Investigations, £50; Dr. C. R. A. Wright—For Continuation of Researches on Certain Points in Chemical Dynamics; on the Determination of Chemical Affinity in Terms of Electrical Magnitudes; and on some of the lesser known Alkaloids, £100; Professor W. K. Parker—For Assistance in Continuation of Researches on the Morphology of the Vertebrate Skeleton and the Relations of the Nervous to the Skeletal Structures chiefly in the Head, £300; Professor A. H. Garrod—For Aid towards Publication of the Second Fasciculus of an Exhaustive Treatise on the Anatomy of Birds, £100.

## HOSPITAL PAY-WARDS.

THE Annual Report of the Hospital for Women, Soho Square, read at the annual general meeting held last week—the Earl of Shaftesbury in the chair—referred to the wards established in 1867 for patients who were able to pay for their maintenance, and stated that the efforts of the committee have been successful in this direction. Since the opening of these wards, one thousand one hundred women have been admitted into them. At the present time, when the question of provident payments in relation to the treatment of the upper classes is under active discussion, it would be interesting to have some further details of these wards, and specially to learn what have been the average payments made by these patients, from what class of society the patients have been drawn, and how far these wards have been wholly self-supporting.

## VENIAL NEGLIGENCE.

A MAN named Charles Hornsey was indicted lately in the Crown Court at Exeter for the manslaughter of a woman who had consulted him about an ulcerated leg. He applied a lotion which, on analysis, appeared to be a solution of corrosive sublimate. The patient died with symptoms of mineral poisoning, and the *post mortem* examination proved death to have resulted from that cause. The prisoner alleged that he had used the lotion in similar cases for thirty years "without anything going wrong"; and the learned judge, Sir James Fitzjames Stephen, Q.C., Commissioner, held that there was no proof of culpable negligence, and withdrew the case from the jury, and the prisoner was discharged. Culpable negligence appears to be a very elastic phrase. An unlearned mind might think this would seem to be a case in which such a phrase was particularly applicable, since it was the one in which there was a large element, to say the least, according to the facts stated, of dangerous ignorance on the part of the person whose calling required him to have adequate knowledge. The ways of the law are, however, often inscrutable.

## HOW TO IMPROVE HOSPITAL FUNDS.

THE Surrey County Hospital at Guildford is languishing in its funds, and various remedies are being discussed. Mr. Albert Napper, in a very sensible letter to the *Surrey Advertiser*, points out that in this,

as in many other local hospitals, the number of beds is in truth in excess of the needs of the really deserving poor of the neighbourhood; and he recommends that the number of free beds should be reduced to twenty-five, the cases to be selected on the ground of their urgency and merits; the remaining beds to be constituted a paying department, and removed from the present category. At present, they seem to be merely used as a cheap means of securing food, medicine, and attendance for the dependants of well-to-do persons, who thus secure an enormous return at their neighbours' expense, their own liberality being evinced by a small annual subscription. We see with satisfaction that the movement of reaction against hospital abuse is extending to county hospitals, which have, even more than the endowed hospitals of London, long been believed to be the strongholds of such abuse.

## SCOTLAND.

THE session 1877-78 of the University of Aberdeen closed on Friday last, with the usual declaration of prizes in the various classes.

DR. ROBERT SCOTT ORR has been elected to represent the Glasgow Faculty of Physicians and Surgeons on the General Medical Council, in room of Dr. Fleming, resigned.

ON Monday last, Dr. P. H. McLaren was elected an assistant-surgeon to the Edinburgh Royal Infirmary, in succession to Mr. Chiene, appointed full surgeon.

THE rainfall in the Crieff district during the past three months was eight inches less than the average amount of the mean fall of the last twenty years, being only 5.36 inches altogether; during the month of March, only 0.41 inch fell.

It is stated that the committee recently appointed to endeavour to come to some arrangement by which the Duke of Buccleuch might be returned unopposed as Chancellor of Glasgow University, are of opinion that they have been successful in their mission, and that the appointment of his Grace will be ratified at the first meeting of the General Council.

ON Tuesday of last week, a *post mortem* examination was made in Glasgow by Dr. Moore, one of the medico-legal examiners for the city, and Dr. J. B. Russell, the Medical Officer of Health, on the body of a young woman named Donaldson, who was supposed to have died from blood-poisoning. The deceased was employed in a hair-factory in the city, and it was imagined that her death was caused by the materials with which she worked. She is said to have been the fourth victim to this form of disease within a month. The report of the examination, which was handed in to the Procurator-Fiscal on Friday, stated that the examiners were of opinion that the girl died of blood-poisoning. An analysis of the contents of the stomach was made by Dr. Douglas MacLagan, but he reported that he found no trace of poison in it.

### PUBLIC HEALTH LEGISLATION FOR SCOTLAND.

ON Wednesday, the 3rd ult., Sheriff Spens of Glasgow read a paper before the Glasgow Philosophical Society, on The Necessity of a General Measure of Legislation for Scotland with regard to Public Health. He first called attention to the present sanitary authority, the Board of Supervision, which he thought had discharged its duties fairly well. As regarded its constitution, however, it seemed to him that there was not a proper guarantee for a proper supervision of public health, and he considered that it should be amended. If the Board were to be continued, as he thought it should, for the control of the Poor-law system, a medical gentleman of eminence should be appointed to advise the Board in sanitary matters. He also advocated the ap-

pointment of a Minister of Public Health. He next referred to urban sanitary authorities, and, alluding to the smaller towns, said the carrying out of the public health provisions was pretty much a sham, because of their permissive character. With regard to the administration, or rather non-administration, of sanitary laws in rural districts, he suggested that the duties of local authorities should be entrusted to a small but practical board of men selected from a larger area than that of a parish. He also pointed out the necessity for amendment and enlargement of the executive machinery for public health purposes, and advocated the amendment of the subject matter of the present sanitary laws with regard to overcrowding, intimation of infectious diseases, prevention of evasion from vaccination, adulteration of food, and other points. A discussion followed, in which Dr. J. B. Russell pointed out that between 1865 and 1873 the death-rate fell, in consequence of defective sanitary laws, increased considerably; while another medical man characterised the sanitary law of Scotland as a perfect sham, on account of its permissive character. A vote of thanks was accorded to the sheriff for his paper.

### DEATH FROM FRIGHT.

A VERY extraordinary case of death from fright occurred at Blakelaw last week. A female carrier from Kelso by some means fell off her cart on the highway adjacent to Blakelaw, and sustained rather severe injuries. She was conveyed to the house of one of the hinds of that place; and the hind's wife, in the house in question, received such a shock, from seeing the bleeding and bruised condition of the woman, that she died shortly afterwards from the effect of the fright.

### VITAL STATISTICS IN LEITH.

THE quarterly returns prepared by the Registrar of Leith show that during the past three months the deaths have numbered 334, being equivalent to an annual mortality of 24 per 1,000 of the population. Sixty-four new cases of typhoid fever, and 423 of measles had been reported by the medical officers. The births numbered 526, of which 25, a very small proportion for Scotland, were illegitimate. One hundred and seventy-seven new cases of measles were reported during the month of March.

## IRELAND.

AT the last meeting of the Medical Society of the King and Queen's College of Physicians in Ireland, on the 3rd instant, Dr. Banks, ex-President of the College, was elected a Vice-President of the Society, in the room of the late Dr. Stokes.

### CORK STREET FEVER HOSPITAL.

DR. CHRISTOPHER GUNN, Assistant-Physician to the Mater Misericordiae Hospital, has been appointed a temporary physician to this hospital. There were two other candidates for the post. The governors deserve much credit for making the appointment, and for the energetic way in which they have endeavoured to provide for the great demands upon them for accommodation during the rapidly-extending epidemic of small-pox. As it is, the beds of the patients in the acute stage of the disease, who are now in the hospital, are represented to be lying close to each other in the wards, and even laid along the passages. On the 1st instant, there were one hundred and ten cases of variola in the hospital, and this number is still very nearly kept up.

### ARMY MEDICAL SERVICE.

THE Council of the Royal College of Surgeons in Ireland have received two hundred and ninety replies in answer to the circular which, as we mentioned last week, had been forwarded by their directions to the medical officers of the army serving in the United Kingdom. Tabulating the ballot papers returned, it is found that one hundred and sixty-four are for the regimental system; ninety-eight are for the unification scheme; while fourteen are for a modified regimental system; and the

same number (14) are for a modified unification scheme; the two latter implying a regimental system in time of peace, modified (as in the New Zealand campaign) to meet the requirements of war. These replies—which, although confidential, have in many instances the names of the officers sending them appended—form the basis of a report of a committee appointed by the Council of the College to draw up a reply to Mr. Hardy's inquiry as to the causes which have produced the existing difficulty in obtaining candidates for the medical department of the army. The committee have also entered into some of the causes of dissatisfaction amongst those now serving in the department. The fact that the roster as now kept has been withdrawn from public inspection, so that no officer can now tell how he stands in regard to foreign service, will, we understand, be particularly alluded to. In former times, the roster-book always lay on the table in the waiting-room at Whitehall Yard, and every officer had an opportunity of ascertaining his position on it. Very sudden and unnecessarily inconvenient, because unexpected, orders abroad are the consequence of the present system; and it also tends to leave a loop-hole for suspicion against "the office", on the grounds of favouritism and jobbing, which may or may not be warranted.

#### BROSNA DISPENSARY DISTRICT.

At an extraordinary meeting of the Brosna Dispensary Committee, recently held, a proposal to recommend Dr. Harold, late dispensary medical officer of the district, for a superannuation allowance of £60 a year was rejected, on the ground that, judging by his physical appearance, he had no claim for a retiring allowance. This treatment appears to us as harsh and unjust, especially when it is remembered that Dr. Harold served as medical officer for the long period of twenty-seven years, and that the small sum proposed was well earned after his long and harassing duties as a dispensary medical officer.

#### FEE FOR CERTIFYING A LUNATIC.

In reference to a note on this subject last week, in which the Guardians of Ballina Union objected to pay Dr. Mahon for examining a dangerous lunatic a fee of £2, we may add that, at a meeting of that Board held recently, the magistrates who signed the order returned it sealed, and also sent a note, stating that they begged to inform the Chairman and Board of Guardians of the Ballina Union, that it was not without due consideration, and taking into account the distance travelled, and the time lost by Dr. Mahon in first visiting the lunatic at her own house, and subsequently accompanying her to their respective residences, that they made an order for £2 to Dr. Mahon. They also informed the Board that they would exercise their duty independent of any resolution to which the Ballina Board of Guardians might come in ignorance of the merits of the case.

#### POST MORTEM INSPECTION.

In consequence of what took place recently at Galway, in reference to the burial of a pauper who died in the workhouse, and by mistake was removed to the anatomical school of the Queen's College, an inquiry was held, on the 2nd instant, by a committee appointed by the guardians; Dr. Brodie, Local Government Board Inspector, being present. After considerable discussion, the following resolution was adopted: "That the provisions of the Anatomy Act have been violated by parties connected with the College and Workhouse; that, had they been carried out, nothing of this lamentable kind, on which the committee had been called to report, could have occurred. The committee draw the attention of the county to that Act, which affords every protection to the inmates of the house, or those seeking relief in the hospital, by enabling them, by merely notifying their intention to be interred straight from the house, thereby effectually preventing any interference with their bodies after death. We do not, however, think that it would be desirable to entirely ignore the benefits that are conferred on humanity by precluding the medical school from obtaining subjects from the house of these bodies unclaimed; and we recommend that most stringent measures should be taken openly, to prevent any recurrence of irregu-

larity, by making the master responsible for the proper interment of any unclaimed pauper body which may have been, with the concurrence of the guardians, given for the good of science to the School of Anatomy." This resolution was brought before the guardians on the 5th instant, but, not meeting with the approval of the majority of the board, it was withdrawn, and the following unanimously adopted: "That in future the master be responsible for the proper interment of all persons dying in the workhouse; and that it be his duty to see that the remains of paupers that are not claimed by their friends shall be interred in the proper place, with due Christian rites, and that no remains be permitted to be removed to the dissecting school of the Queen's College." This determination of the guardians is most important in regard to the Medical School of the Queen's College; and, if they can legally withhold the bodies of unclaimed paupers, it will be of serious detriment to the College, and, we may add, to all anatomical schools in Ireland.

#### THE SMALL-POX EPIDEMIC.

WE noted last week the culpable loss of time of which the Board of Guardians of the South Dublin Union had been guilty in deferring, week after week, to take prompt and definite action as regards provision for the accommodation of small-pox patients and convalescents. Owing to the crowded state of the Cork Street Fever Hospital, and the time that would be occupied in building sheds on its grounds, the proposed arrangement with the governors of the hospital, to which we also referred last week, was clearly inadequate. Moreover, it did not meet the urgent need for immediate accommodation which the serious and rapid extent of the epidemic required. The Local Government Board, having ineffectually called the attention of the guardians to their responsibility in this matter and the need for energetic action on their part, wrote to them a second time last week, again calling their attention to the inadequateness of the steps they had taken to provide the requisite hospital accommodation for poor persons, and to protect the poor and the community at large from the great danger of having cases of small-pox left in the residences of the patients. The Local Government Board's communication further clearly stated that it would not suffice to refer the matter to committees, or to defer action from one weekly board day to another; and finding from former experience that it was of no use simply bringing the *lâches* of the guardians under their notice again and again, they were informed that if they separated on the day of receiving this communication without taking effectual steps to meet the emergency, the Local Government Board would consider whether a necessity had not arisen to exercise their power and dissolve the Board of Guardians, appointing paid officers to carry into execution the provisions of the Act (18th of 10th Vict. chap. 31), in cases in which, through the default of the guardians, the duties were not effectually discharged. This threat to dismiss the guardians, as it was termed, had the desired effect, and sheds were at once secured, at an expenditure of probably some £2,000, for small-pox patients. Mr. Edward H. Byrne has been appointed temporary medical officer to these sheds, at a salary of £3 a week. Sixty-six deaths from small-pox have been registered in Dublin for the seventeen weeks ending March 30th. According to a recent report of the Superintendent Medical Officer of Health, Dr. Mapother, a large proportion of the cases are of the modified form; and in these, the deaths do not probably exceed 3 per cent.; while in the unprotected, it was at least 33 per cent. It is to be regretted that in some cases the authorities allow convalescents to leave hospital while capable of spreading the disease. We are glad to see that the Public Health Committee of the Corporation have recognised this, and have urged the hospital authorities to retain such patients until all danger is past. They have also directed that the attention of the South Dublin Union Guardians be called to the powers conferred on them by the Irish Poor Relief Extension Act, which enables them to provide temporary accommodation for parties other than paupers during the disinfection of their dwellings, and that the board be requested to provide such accommodation.

## THE GENERAL MEDICAL COUNCIL.

A SESSION of the General Medical Council commenced on Wednesday, April 10th, at 2 P.M.; Dr. ACLAND, President, in the chair.

*New Members.*—The official notices of the appointments of Dr. J. B. Pettigrew as representative of the Universities of Glasgow and St. Andrew's in the room of Dr. Allen Thomson; of Dr. R. S. Orr as representative of the Faculty of Physicians and Surgeons of Glasgow in the room of Dr. J. G. Fleming; and of Dr. Andrew Fergus as Crown representative for Scotland in the room of Mr. Lister, having been read, these gentlemen were introduced, and took their seats.

### PRESIDENT'S ADDRESS.

The PRESIDENT addressed the Council as follows.

The Medical Council has this year been called together thus early in the Parliamentary Session to enable it to carry forward, and if possible to conclude for a long time to come, its deliberations on the Amendment of the Medical Acts. It may not, however, be assumed that in one sitting the Council will be able completely to fulfil its duty in this respect.

Although the business of the Council has of late increased, there is not much that demands your instant attention, except the Bills affecting the profession of medicine, actually before Parliament or in contemplation, together with questions arising out of them.

Since your last meeting, steps have been taken to make the *Medical Register* more accurate than heretofore. The volume which is now in your hands has in it several thousand corrections, besides other alterations in the typographical arrangements, and some additional prefatory matter. For these, as for other office improvements, the Council is indebted to the Registrar.

The minutes of the Executive Committee will have informed the Council of communications from the Board of Trade relating to weights and measures, and from the Registrar-General on important points connected with the relation of his office to the Medical Council.

Communications concerning the removal of names from the *Register*, and other subjects connected therewith, will, when required, be laid before you.

Acting under your instructions, the Executive Committee made applications to the various licensing bodies concerning the insufficiency of general education in many of the candidates who present themselves for professional examination. The answers from these authorities will be laid on the table. Papers written by registered practitioners have been confidentially forwarded to me as President, to show that the neglect of the practice of writing the English language, permitted by some examining boards, cannot be reprehended in too strong terms, if ordinary literary culture is to form an essential part of the training for a scientific profession.

The scheme for the Conjoint Examining Board in England has been industriously elaborated under the presidency of Sir James Paget. It may be permitted to one of the members of the Committee to say that the discussions among the representatives of the several licensing bodies have shown, when considered in connection with the recommendations of the Council, and the evidence given to it through Mr. Syme's Committee in 1868, that much remains to be done before this country can rightly claim to have settled views on the course, time, and methods indispensable for securing a sound education for the practice of medicine. It becomes more and more clear that the examining boards regulate the steps by which a student is fitted to pass an examination on a particular day. The question is, whether thus we best prepare him for the practical discharge of his life-long work. This proves the great importance—nay, the necessity—of having examining boards composed of the highest and fittest persons for the special duty of examining, that can be induced to undertake it. Another important conclusion may be drawn—so trite, indeed, as to seem almost impertinent to name it—that the opportunities for learning in different hospitals and universities are at least as diverse as the mode of testing results has ever been. As regards scientific teaching, an eminent teacher (Mr. Savory) has again lately drawn public attention to the importance of organising the means for the best scientific teaching not necessarily connected with the chief place of clinical teaching, the hospital.

A recommendation just made by the Commissioners of the Universities of Scotland, that no candidate shall be admitted to examination in Human Anatomy or Physiology, or in any purely medical subject, unless he has passed an examination in Natural Philosophy, Chemistry, Physiology, Botany, and Zoology, as constituting the second and third groups of the fifth or Natural Science department for the degree of M.A., will have an important bearing on the time and place necessary

for scientific training preparatory to medical study, and for professional study, respectively.

Considerations of this kind will force themselves on our minds whenever we discuss the nature and extent of examination rules to be made generally binding by the authority of the Medical Council.

Documents will be laid before you from various bodies affected by the Medical Acts Amendment Bill presented to the House of Lords on March 19th.

At the close of the session of last year, the Medical Council urged on the Lord President that a Bill should be brought in by the Government to amend the Medical Acts. The Lord President, acknowledging the importance of the objects which the Council presented to his view, promised his best attention to the whole matter. His Grace has fully redeemed this pledge, and, whatever be the result, deserves the warm thanks of all who are interested in the settlement of medical legislation.

Immediately after the summer recess, the Lord President personally considered all the materials which he had before him for amending the Medical Acts, whether obtained from the Council or from other sources.

The Medical Council had pressed on his Grace, and through him on the Government, the importance of an early settlement of the following five subjects, viz.:

1. The recognition of Foreign and Colonial qualifications in England.
2. The privileges of women in regard to medical qualifications.
3. The appropriation of penalties under the Medical Act.
4. To some extent, the education of midwives.
5. And, indirectly, the emendation of the law affecting certificates of lunacy.

After full consideration of these several subjects, the Lord President informed me that the Government were of opinion that it might in the end be more satisfactory to the Council, as well as to the legislature and to the country, to bring into a Bill, together with these points, certain others for which legislation had at one time or other been desired.

On all these matters, the Lord President sought from me information; and I gave him such as I believed would most nearly express the opinions of the Council. But I would not take on myself to advise his Grace to omit from a Government Bill any of the subjects relating to our profession which might be regarded as of public importance, even though on some of them the Council had not expressed a definite opinion.

There is a great temptation for your President to summon the Council on every occasion of consequence, and to throw responsibility at every turn on the Executive Committee. But both are so heavy a charge to the finances—the Committee costing nearly £50 for one afternoon, the Council £400, if summoned for one day (or an average of about £165 daily for a whole session)—that the President must often be content to bear the burden which you impose upon him, feeling sure of your support where he deserves it, and always certain of your lenient judgment.

This last winter, indeed, the task was not difficult, for the Lord President seemed to have one only desire, to know how best to legislate for the medical profession in its varied relations to the body politic, and in its own complex inner organisation. Nor can it be without interest to this Council, that, looking on this body as the appointed exponent of a great section of society, he had desired in all ways to aid and support it.

The important Society of Obstetricians had pressed repeatedly on the public mind the desirability of complete legislation concerning midwives. It is, moreover, manifest, that the vexed question of the relations of the medical profession towards women, and the fitness of women to practise the whole of medicine and the whole of surgery, or any part or parts of medicine and surgery, could not be completely decided upon without a discussion on the education and organisation of the midwives of the future.

The body of Dentists—a class in the body politic of whom, when the actual suffering which they seek to prevent and to alleviate is taken into account, one must say that it is an important and useful body—urged on the attention of Parliament their claims to better organisation, depending on and justified by a higher education and fitness.

The Lord President was little disposed to neglect the numerous persons engaged in these occupations respectively—professionally occupied as they are—through the entire country, nor to sever those classes thus growing in importance, as social organisation becomes more perfect, from the medical profession and the Medical Council.

Having decided, then, to consider all outstanding questions known to affect the profession of medicine, and through it the public at large, the Lord President could hardly have left untouched the subject of examinations, which was handled in a complete and masterly way in the

Bill so well known as Lord Ripon's Bill. Though the Council had not last year pressed on the Lord President's notice the subject of diminishing the number of ways by which the licences could be obtained, he knew well the anxious thought which the Council had long and often bestowed upon it; he was acquainted with the resolutions which the Council had passed with regard to Lord Ripon's Bill; and fully estimated the importance to the public of one uniform and satisfactory test of qualification for entry to the *Medical Register* in each branch of the United Kingdom.

The Lord President could not, therefore, but entertain the question. If a Bill was brought in, either without Lord Ripon's clauses relating to examinations, or without some modification of them, it was clear that it would have to be argued in Parliament that the existing arrangements need no alteration. Could this argument be maintained? Is the Medical Council fully agreed upon it?

It is often said that the whole profession considered, when Lord Ripon's Bill was brought before Parliament, that the mode of conducting examinations by the examining bodies was the subject that most urgently called for parliamentary revision. It is not, however, necessary now to revert to the circumstances which led to the withdrawal of the Bill.

But in this the Council will assuredly be unanimous, that it is in the interest of all persons concerned—in the interests of the public, of the Council, of medical teachers, and of students—no longer to delay a final settlement of the principles on which examinations shall be conducted in England, in Scotland, and in Ireland. Some evils have disappeared: some new difficulties have perhaps arisen. Education, examination—nay, even knowledge itself—have greatly altered within the last twenty years. Those who have attended the more than fifty conferences which have taken place in England, in the belief that they were discharging a great public duty, may fairly ask to be released if their labours be not shown to be material for the public interest, or if the apparent benefit in one division of the kingdom should be productive of other and unknown evils through any other division of the kingdom. It is clear that the matter cannot be decided without frank and full discussion both in this Council and in Parliament. The discussion here will be dispassionate, and based upon correct estimates of the present and of the past state of the several licensing bodies, and of the popular sentiment. That sentiment is certainly in favour of making it impossible that nineteen separate examining and licensing boards, with their varied qualities, should co-exist. The public are convinced that there are dangers in the continuance of so many modes of entering the profession, and think the system of inspection offers only a cumbrous and fitful check to constant danger. There are not wanting signs that some, both within and without the medical profession, would prefer State-appointed examiners, or an examining board appointed by this Council, not only to the present system of many examining boards—with permissive power to combine—but would even prefer State-appointed examiners to persons appointed by the present universities and corporations in combination. It is well known that the framers of the Act of 1858 expected the permissive principle of combination, under Section 19 of the Act, to be more largely adopted than it has been.

It would ill become me to use any arguments on one side or the other, inasmuch as my function is almost limited to collecting facts for your consideration. Yet I cannot but observe in this relation that it will be a grave misfortune for our generation if it be forced to the conclusion that our ancient medical institutions, hitherto self-administered, must abdicate their functions of guiding the education of our youth. And that is the risk that is run. One Government might give to this Medical Council a task which the corporations decline to execute, namely, the making the national examining boards. Another Government might assign it not to this Council, but to a single person, who, however able, might not possess the combined judgment of the many and eminent minds brought together of necessity by a representative board.

The Lord President, as the Council is aware, has not at present elected to make the formation of a single board compulsory for each branch of the United Kingdom. It is not too much for me to say that, as his Grace hoped for discussion, and for the freest expression of opinion from all who are entitled to be heard, and having referred the Bill to this Council, the question for us to consider is whether union is expedient or requisite. The form in which the proposition is put is not perhaps of much moment for the issue. But it cannot be less acceptable to the various authorities to ask the Government, after discussion, to grant more extended power for good, than to have had to protest against unnecessary interference, and uncalled for dictation for which the Council had not applied.

I cannot help noticing, with regard to those who in 1858 first undertook the working of the Medical Act, with all its conflicting interests,

that while, during the twenty years that the Act has been in operation, in Ireland one licensing body alone has changed its representative, Scotland sends only one of its original members, England sends but two such members, and not a single original nominee of the Crown remains in the Council. It cannot be amiss, therefore, to take the sense of the existing Council in the most unfettered way on the state of the medical examinations in the country, in order that it may fairly face the work of the future.

It would waste the time of the Council if the details of the Bill that has been in the hands of all the members between two and three weeks were even enumerated. The aim of the Bill is, without doubt, to supply all the known deficiencies of the Medical Acts, and, if possible, to adjust the machinery of this Council so that it may not be distracted from its strict work, the regulation of medical education and the watchful care of a great profession, in the public interest.

The principal objects of the Bill (I quote from the Lord President's speech) "are, first, to require a person registered in the *Medical Register* to have both a medical and a surgical qualification; second, to allow the registration of foreign and colonial practitioners; third, to further restrict the assumption by unqualified persons of designations implying qualifications; fourth, to make further provision for the uniformity of the standard in the grant of qualification in the United Kingdom; fifth, to make provision for women similar to that intended to be made by 39 and 40 Vic., cap. 41, commonly called Mr. Russell Gurney's Act; sixth, to make provision for the examination and registration of dentists; seventh, to make provision for the examination and registration of midwives; eight, to make amendments in the Medical Act of 1858 as regards the registers, erasures from the *Register*, the certificates of medical practitioners under the Lunacy Acts, the qualification of medical officers in colonial ships, and other minor matters".

It was truly added by the Lord President, that this measure "deals with a subject of great importance, but one of great complexity, and which, when legislation is proposed in respect of it, requires great consideration in numerous details. The subject is one for which there should be no hasty legislation, and I should hope that by the time the Bill comes on for a second reading, we shall have the benefit of being in possession of the views of all persons in the country who may be interested in its details, and who are competent to give advice on the matter. I hope I need not add that we shall be most ready to give an attentive consideration to all suggestions which may be offered with the object of securing a good and useful measure, and one which will be satisfactory both to the medical profession and the public at large".

Before quitting the consideration of this part of the work of the session, I beg you to excuse me if I seem in any improper way, or indeed in any sense, to be the interpreter of a measure to which the Government has given much thought, which is full of delicate and difficult questions, and which deals with great institutions and important persons.

I need not say that I have no functions in the matter, except, first, to carry out as far as I can your desires; and secondly, in your absence to act to the best of my judgment on your behalf.

The grave anxiety of the Eastern Question has made it difficult to arrange the times and the mode for the introduction and the readings of the Bill in the way best calculated to carry a Bill this session, and to suit the time and convenience of the Medical Council. But that way has been sought—I trust, attained.

Let us hope that we may come to unanimous conclusions as to the changes which may be required in the Bill, and then that it may this session become an Act with good effect.

This done, might we not hope for the consolidation of all the Medical Acts, with further power if necessary? Thus would be ended the first twenty years of combined effort towards harmonising the work of the time-honoured institutions which have nurtured in Great Britain the science and practice of medicine. Thus would the Council go forward unfettered to accomplish further work, in aid of the great demands made, in many ways, upon a profession, whose aim is so to pierce the secret of all life, that it may strengthen individual and national health, relieve all physical suffering, diminish much social evil, and soothe or avert the inevitable end.

Dr. ANDREW WOOD moved, and it was unanimously resolved: "That the President's Address be entered on the minutes."

*Committees.*—The following Committees were appointed: *Business*—Dr. A. Wood (Chairman); Dr. A. Smith; Dr. Leet; Dr. Haldane; and Dr. Pyle. *Finance*—Dr. Quain (Chairman); Dr. Pitman; Dr. A. Smith; and Dr. Orr.

*Medical Acts Amendment Bill.*—A letter was read from the Lord President of the Privy Council, accompanying copies of the Bill, and

asking the President of the Council for any observations which the General Medical Council might have to offer with regard to the Bill.

There were also read copies of a Memorandum by the Royal College of Physicians of London, and by the President and Vice-Presidents of the Royal College of Surgeons of England, stating various objections to the Bill. Appended to the Memorandum of the Royal College of Surgeons were the following resolutions, adopted by the Council of the College, at a meeting held on April 1st:

1. That the report of the President and Vice-Presidents on the Government Bill for amending the Medical Acts be approved, and be entered on the minutes of the Council.

2. That the consolidation of all present licensing authorities into conjoint boards, one for each division of the kingdom, recommended for many years past by the General Medical Council, and accepted by the House of Lords in 1870 as a principle for compulsory legislation, is an object to which the College attaches the highest importance, and for which it has long been exerting itself: that already, by taking part in the settlement of a voluntary joint scheme for England (approved by the General Medical Council), the College has shown its willingness to make all needful sacrifices for that object; that, in the opinion of the Council, the object would not only remain unpromoted, but even the progress already made towards it in this division of the United Kingdom would be seriously endangered, and in all probability be lost, if the Legislature were now to affirm that it leaves the principle of joint examinations for the option of the individual medical authorities.

That, therefore, as regards Clauses 3 and 14 of the present Bill, the College hopes it may not be called upon to surrender any of the independence which it now has in respect of its diploma and examination rules, unless such surrender be in contribution to a general system, which (so far as minimum qualifications are concerned) shall make joint-examinations compulsory for all the divisions of the United Kingdom.

That, further, as regards Clause 14, the College, while recognising the necessity of providing for supervision by the General Medical Council in all the essentials of medical education and examination, would not think it desirable to give to that body the initiative in framing examination rules, either for the respective joint boards, should such exist, or, should such not exist, for the separate authorities.

3. That, as regards Clause 23, the College recommends that the Clause be withdrawn in favour of the less centralised plan of Sir John Lubbock's Bill.

4. That, as regards Clause 24, the College recommends the withdrawal of the Clause, with a view to the subject being dealt with separately from any question of amending the Medical Acts, and mainly on a system of local, rather than of central, responsibility.

5. That, as regards the granting of qualifications to women for entering upon the medical profession, the College approves the giving to the authorities amended powers for optional exercise in this matter, but recommends that the powers be so given as to allow the authorities reasonable discretion to distinguish in their examination rules and diplomas between men and women; provided that the examinations of the two sexes be in the main equivalent for like certificates or diplomas.

6. That, as regards the remaining provisions of the Bill, the College gives general approval, but authorises the President to recommend such minor amendments as he and the Vice-Presidents may find desirable.

7. That the President and Vice-Presidents be instructed to request an interview with the Lord President in order to set before him the views of the Council on his Bill; and that it be an instruction to them, in any such interview, particularly to explain to his Grace the regret which the Council feels, on public grounds, that the Bill does not contain any provision for enforcing joint examinations in each division of the United Kingdom.

A letter to the President from the Chairman of the Medical Reform Committee of the British Medical Association, sent with a copy of the Medical Acts Amendment Bill approved by the Association, and reports of the Medical Reform Committee, and the President's reply, were read.

Dr. HUMPHRY moved the following resolution:

"In 1870, this Council passed the following resolution, by a large majority, and after much deliberation:

"That this Council is of opinion that a joint examining board should be formed in each of the three divisions of the kingdom, and that every person who desires to be registered under any of the qualifications recognised in Schedule (A) to the Medical Act shall be required, previously to such registration, to appear before one of these boards and be examined in all the subjects which may be deemed advisable by the Medical Council; the rights and privileges of the Universities and Corporations being in all other respects the same as at present.

"The Council has subsequently sanctioned a scheme for an Examining Board for England made in conformity with that resolution.

"The Council adheres to the principle of that resolution, and is of opinion that no medical legislation relating to examinations will be satisfactory which does not provide for the formation of an examining board in each of the three divisions of the kingdom, and direct that every person who desires to be registered under the Medical Act shall be required to appear before one of these boards and be examined in the subjects which may be deemed necessary by the Medical Council."

Sir JAMES PAGET seconded the motion, which was opposed by Dr. Andrew Wood and Sir Dominic Corrigan, and supported by Dr. Rolleston.

The discussion was adjourned.

On Thursday, the discussion on Dr. HUMPHRY's motion was resumed. It was supported by Dr. Rolleston, Mr. Teale, Dr. Sorrar, Dr. Quain, Sir W. Gull, and Dr. Pitman; and opposed by Sir D. Corrigan, Dr. Haldane, Mr. Turner, Dr. A. Smith, and Mr. Macnamara.—The discussion was again adjourned.

## BRITISH MEDICAL ASSOCIATION.

### EXTRAORDINARY GENERAL MEETING.

[In last week's JOURNAL, owing to the great length of the report, we gave only a brief summary of the proceedings of the last part of the Extraordinary General Meeting at Birmingham. We now in due course present the fuller report.]

The PRESIDENT said that, as the gentleman who had undertaken to move in relation to the question of the privileges of lady members was ill, and the hour was late, the subject would be deferred until the annual general meeting.

Mr. O. PEMBERTON stated that the decision of the President had come upon him by surprise. He contended that something should be done between this time and the annual meeting in regard to the ladies' question. He moved: "That a subcommittee be appointed to consider the question of the privileges of lady members; that such subcommittee be empowered to take counsel's opinion; and that they report to the next annual meeting."

Mr. LISTER held that it would conduce very much to the interests of the Association, if some steps could be taken in the interval between this time and the annual meeting, so as to prevent the matter from being presented before the Association, at the next annual meeting, in a crude form. He seconded the proposal of Mr. O. Pemberton.

Mr. SAMPSON GAMGEE contended that the question should be left in the hands of the Committee of Council. The meeting had just expressed their entire confidence in the Committee, and there was not the slightest reason for taking this question out of their hands. It was, he urged, very desirable that legal opinion should be taken in the matter, and he moved, as an amendment: "That the Committee of Council be requested to take legal opinion upon the subject of the privileges of lady members of the Association."

Mr. VOSE SOLOMON seconded the amendment.

Mr. PEMBERTON said that the only reason he had for objecting to the amendment was, that the Committee of Council had been hitherto very reticent in taking steps in regard to the presence in the Association of lady members, until the question was raised by the expressions of members so distinguished as Sir William Jenner, Dr. Bennett, Mr. Lister, and others. Even if he found himself in a minority, he should press his motion for an independent committee.

Dr. WADE held that the motion displayed a lack of loyalty to the Committee of Council, and he entirely repudiated the idea set forth that the Committee of Council had shown a want of energy in dealing with the question. Neither had that body committed itself to any particular side, as was indicated in the motion by the subject being taken out of their hands, as Mr. Pemberton proposed. The first lady elected to the Association (Mrs. Garrett Anderson) was elected by the Metropolitan Counties Branch, the Branch of which the gentlemen who were prominent in opposing the presence of lady members in the Association were members. [Hear, hear.] They were members of that Branch, moreover, at the time of Mrs. Anderson's election to membership. [Hear.] Some years elapsed, and no exception was taken during those years to the membership of Mrs. Anderson; nor had the Committee of Council said one word in reference to this membership—no word of abrogating it, no word in opposition to it. Thus, tacit assent was given to the action of the Metropolitan Counties Branch in electing Mrs. Anderson. [Hear.] The second lady member (Mrs. Hoggan) applied to the Committee of Council for election; and the

Committee of Council, taking into consideration the fact that the first lady member had been elected by the largest Branch in the Association, and the fact also that the election had been agreed to tacitly by the Association, elected the second lady, and he thought rightly. At the Edinburgh meeting, the question as to the presence of lady members was first raised, on the motion of Mr. Pemberton, seconded by Dr. Marshall. The result of this was, that the General Secretary was directed to take the votes of the members of the Association by circular upon the question of the admission of lady members, and to report the result to the next annual meeting. Up to the time when that vote was taken, the Committee of Council had, of course, no cognisance of the feeling and views of members; the Committee of Council could not tell in what way the vote would result, and they could not propose any by-law on the subject, as notice had to be given of any proposed new by-law. Then, too, the Committee of Council supposed that the gentlemen who had brought forward the subject, and had taken it up with much spirit, would themselves give notice of any proposed by-law which they would desire to see carried in accordance with the result of the vote. [*Hear.*] So far, therefore, from the Committee of Council showing any neglect in the matter, it was Mr. Pemberton, and his colleagues who had brought the matter forward in the first instance, who had failed in their duty in not bringing the subject before the Association at the annual meeting following the vote, and in not asking the Committee of Council to bring it forward. Mr. Pemberton and his colleagues were quite within their rights in introducing the subject at the Edinburgh meeting; but with the exercise of their right there was the duty of proceeding with the question; and, when they had obtained the vote, they should either have proposed a by-law themselves, or have asked the Committee of Council to do so. [*Hear.*] Under these circumstances, to appoint a special subcommittee to deal with the subject, and to take the matter out of the hands of the Committee of Council, would be to pass a slight upon the Committee of Council, which that body was in no way deserving; and he trusted that the amendment would be accepted.

Dr. EASTWOOD drew attention to the fact that the Committee of Council, on his proposal, seconded by Dr. Gigg, had agreed to the following resolution: "That the Committee of Council is of opinion that women should not be admitted as members of the British Medical Association, and that a by-law to that effect be submitted to the annual meeting." The present meeting had not the power to deal with the question to the extent of passing a by-law, and so the Committee of Council had referred the point to a subcommittee. Thus, the Committee of Council had not been in any way remiss in the matter, but had acted upon the subject when it was brought before them, and as soon as they had seen any necessity for action. He contended that those who had acted with the mover and seconder of the resolution at the Edinburgh meeting were responsible for not acting up to their convictions, in not bringing forward any proposal for a by-law to meet the circumstances under discussion when the vote of the members had been taken under their own proposal. They had, therefore, condemned themselves in not bringing forward the by-law, and there was no necessity for the proposed subcommittee external to the Committee of Council, as the Committee of Council had committed themselves to the framing of a by-law to meet the circumstances in which the Association was placed by the admission of the lady members.

Dr. BORCHARDT said the motion and amendment both spoke of the "privileges" of the lady members. He objected to the word "privileges"; for he conceived that the ladies, being *de facto* and *de jure* members of the Association, had rights. The legal question involved was a very immaterial one by the side of the fact that the very honour of the Association was involved in its action.

Mr. PEMBERTON rejoined that he and those with him considered that the ladies had no rights in the Association.

Dr. BORCHARDT added that Mr. Pemberton might think as he had stated; but that question had yet to be decided. Then, too, there were those who thought that, if the ladies had no legal rights in the Association, it would serve the best interests of the Association better not to attack those who had become members. The question ought to be considered in the fulness it deserved, and he should move that "rights" should be substituted for "privileges" in whatever resolution should stand first before the meeting.

Mr. S. GANGEE said he would substitute the word "rights" for "privileges" in his amendment.

Mr. LAWSON TAIT submitted that it was not competent for the Association to take away the "rights" of any members, or to discuss if those rights could be taken away, and that therefore the amendment should not properly be put.

The PRESIDENT ruled that the amendment was in order.

A vote was taken by show of hands. This was not decisive; and

then a division was called for, in the midst of which many members left. The division gave 40 for the amendment, and 38 against it. The amendment was then declared to be carried.

## MEDICAL TEACHING AT CAMBRIDGE.

THE Study Syndicate of the University of Cambridge lately referred to the Board of Medical Studies the important question raised in their fourth report, as to whether it is "desirable to attempt to found a complete Medical School in Cambridge, so as to make it possible for a student to complete his whole medical course here", or whether it is "better for all concerned, whilst making the teaching at Cambridge as perfect as possible in the scientific subjects which are the basis of medicine, to leave students to carry on elsewhere the greater part of their clinical studies, and most of what relates directly to the practice of medicine". They have received the reply which they append, and which they think deserves the careful consideration of the Senate.

The Board of Medical Studies have now considered the question referred to them by the Vice-Chancellor on behalf of the Studies Syndicate, and they have returned an extremely important and satisfactory reply.

They consider that it is inexpedient that students should, as a general rule, complete their whole professional education at any single medical school, and that it is therefore desirable that students should pursue their studies away from Cambridge for a year or more before commencing practice, either before or after their final M.B. examination. They believe, however, that it would be in most cases advantageous to students to carry their medical studies in Cambridge further than is usually done at present, and in some cases as far as the final M.B. examination; and they are, therefore, of opinion that the University should provide systematic instruction in all the subjects necessary for a medical degree, as is done at other Universities.

In order that this may be carried out satisfactorily, they think that the University should provide—

I. A Professor of Pathology. There seems to be no reason, they observe, why the study of pathology should not be most thoroughly and effectively carried on in Cambridge. For this purpose, the University should secure the services of the ablest man that can be obtained, who should devote his whole time and energies to his subject. To ensure this, he ought to be debarred from the private practice of medicine, though it would be most desirable that he should hold a hospital appointment. Under these circumstances, they recommend he should have a stipend of not less than £700 a year. He would ultimately require a Demonstrator.

II. A Professor of Surgery. As he need not be debarred from the private practice of surgery, they consider that a stipend of £300 a year would probably be found sufficient.

III. Systematic teaching in (1) Midwifery and the diseases peculiar to women; (2) Medical jurisprudence; (3) Sanitary science; (4) Mental diseases. This might probably, they think, be provided for £700 a year, or thereabouts; but some, at any rate, of these subjects might ultimately be represented by eminent men upon whom the University might confer the title and status of a professor.

IV. Systematic Clinical Teaching. This is already supplied to a considerable extent by the physicians and surgeons to Addenbrooke's Hospital. It is, however, not definitely connected with the University, or subject to academical regulations. The University might, they consider, with advantage appoint (1) One or more Clinical Lecturers in Medicine; (2) One or more Clinical Lecturers in Surgery; (3) An Assistant Teacher of Medicine and one of Surgery.

It would be the special duty of the two Assistant Teachers to give systematic elementary instruction in Clinical Medicine and Surgery to the younger students. Stipends of £100 a year each would probably suffice for the present for these lecturers and teachers. Other special subjects, such as Ophthalmic Surgery, ought to be provided for in a Medical School which aims at completeness. Arrangements for teaching them might, however, be trusted to grow up with the growth of the School.

This report is signed by Dr. G. E. Paget; Dr. G. M. Humphry (only as regards Nos. I and II and part (3) of No. IV); Dr. P. W. Latham; Dr. J. B. Bradbury (except provision that professor of pathology should not be allowed to practise); Dr. G. D. Liveing; Mr. Conitts Trotter; and Mr. William Garnett.

We feel sure that the profession at large will welcome this timely, thoughtful, and well-arranged scheme for bringing the University of

Cambridge into satisfactory position in respect to its duties in educating men for the great profession of medicine. It will, we trust, have the collateral effect of shaming Oxford out of its present systematic and determined neglect of that duty.

### THE HARVEY TERCENTENARY MEMORIAL FUND.

WE are pleased to learn that, in response to the appeal for further donations to the above Fund, which we published a short time since, the following subscriptions have been promised or received.

£10 10s. each: Metropolitan Counties Branch of British Medical Association, Dr. Walter Moxon, and the Marquis of Tweeddale.

£5 ss. each: Mr. W. Allingham, Dr. R. L. Bowles, (second donation), Mr. S. W. Bradnack, Mr. S. Eastes (second donation), Dr. G. S. Jenks, Mr. G. M. Scholey (second donation), and Dr. Wickham Legg.

£5 each: Boxes at Canon Jenkins's lecture, Mr. R. Benyon (per Dr. Bowles), Mr. H. A. Brasse, M.P., Mr. F. D. Brockman, a Friend (per Dr. Quain), Dr. F. B. Hawkins, Miss Phillips (per Dr. Bowles), Mr. Russell Scott, and the Duke of Westminster.

£3 3s. each: The Earl of Glasgow (per Dr. Bowles), Alderman D. H. Stone, Mr. W. F. Teevan, and Dr. Hermann Weber.

£2 ss. each: Mr. C. Bader, Mr. John Ball (per Dr. Bowles), South Wales and Monmouth Branch of British Medical Association, Dr. W. C. Begley, Mr. H. B. Bradley, Dr. Michael Foster, Dr. E. Furley, Mr. John Hart, Mr. F. G. Hemiques, Canon R. C. Jenkins, Dr. T. Jervis, Mr. James Kelcey, Dr. Morell Mackenzie, Dr. W. J. K. Millard, Dr. Withers Moore, Professor W. Odling, F.R.S., Mr. E. Saunders, Mr. W. E. Springall, Mr. Frederick Symonds, Rev. C. J. Taylor, Mrs. Upton (per Dr. Bowles), Mr. G. Vaughan (per Dr. Bowles), Dr. Gerald F. Yeo.

£2: Mr. W. Deedes, M.P.

£1 1s. each: Sir J. Alderson (per Dr. Bowles), Dr. J. B. Allan, Dr. T. C. Allbutt, Dr. F. Beach, Mr. R. W. Boarer, Rev. C. Bosanquet, Dr. J. H. Bridges, Dr. Walter J. Bryant, Mr. Frank Buckland, Dr. T. Bazzard, Mr. E. Carver, Dr. W. Cholmeley, Mr. O. Clayton, Dr. W. F. Cleveland, Mr. T. Cobb, Mr. J. B. Collins, Dr. S. Coupland, Dr. T. Davies-Colley, Dr. J. Hall Davis (second donation), Miss Day (per Dr. Bowles), Dr. J. B. Ditchfield, Dr. Allan Duke, Mr. C. F. Du Pasquier, Mr. F. Eastes, Dr. John Easton, Dr. R. Farquharson, Dr. W. Farr, F.R.S., Mr. John Fittess (second donation), Dr. T. B. E. Fletcher, Dr. J. G. Glover, Mrs. James Green, Mr. J. Hackney, Dr. T. Hawksley, Miss Hunter (per Dr. Bowles), Rev. F. Husband, Mr. Sydney Jones, Mr. W. H. Lamb, Dr. J. C. Langmore, Mr. W. B. Langmore, Mr. E. H. Lushington, Mrs. Joseph Maudslay, Dr. R. McDonnell, Dr. A. Meadows, Dr. A. G. Medwin, Mr. A. Medwin, Mr. J. C. Merriman, Dr. S. Mitchell, Dr. T. Moffatt, Mr. John Morgan, Dr. T. Morton, Mr. Albert Napper, Miss Ogilvie, Hon. G. Pepps, Mr. C. J. Pinching, Dr. W. L. Purves, Mr. J. Reid (per Dr. Bowles), Dr. F. T. Roberts, Dr. C. Royston, Mr. J. Rushforth, Lord Arthur Russell, M.P., Dr. H. J. Sanderson, Dr. G. H. Savage, Mr. L. Simon, sen. (per Dr. Bowles), Mr. Thomas Spencer, Mr. N. H. Stevens, Dr. J. Sherwood Stocker, Mr. H. S. Taylor, Dr. G. D. P. Thomas, Mr. R. C. F. Thomas, Mr. W. P. Thornton, Dr. J. C. Thorowgood, Mr. F. Toulmin, Dr. T. W. Trend, Dr. J. Underwood, Mr. R. E. Unthank, Mr. Francis Vacher, Mr. Osman Vincent, Mr. W. W. Wagstaffe, Dr. T. Whipple, Dr. H. C. Wildash, Dr. C. T. Williams, Dr. E. Williams, Dr. A. Wiltshire, Mr. G. L. Wood, and Madame Zafie.

£1 each: Captain H. Alcock, Mr. John Dugdale, and Mr. E. Lowdell.

10s. 6d. each: Dr. G. M. Bacon, Mr. G. Brown, Mr. T. M. Butler, Dr. R. K. Casley, Mr. C. W. Chaldecott, Mr. G. Fisher, Mr. D. J. Francis, Dr. John Jackson, Dr. Norman Kerr, Dr. H. G. Knaggs, Dr. John Morton, Mr. A. A. Napper, Mr. R. J. Pye-Smith, Mr. T. J. Schollick, Mr. C. J. Sells, Dr. J. R. Stedman, Mr. J. H. Sutcliffe, Dr. W. H. Taylor, and Dr. T. J. Walker.

10s. each: Dr. H. Harris, Mr. J. M. Hind, Mr. J. W. Howard, Mr. A. E. T. Longhurst, Mr. G. F. Naylor, Mr. R. Paramore, Mr. James Rose, Dr. J. C. Steele, Mr. Samuel Watson, and Mr. J. G. Westmacott.

During the past week, the new subscriptions promised to or received by the London honorary secretary amount to just £100. The Councils of the medical societies have further recommended their respective Societies to contribute to the Fund; but this cannot of course be done until the next meetings in either case. We learn that the Earl of Radnor has kindly expressed his readiness to grant a site of land at Folkestone for the purposes of the statue. All things point, in fact, to an early realisation of the wishes of those who have the project at heart. But in order to accomplish their purpose they cannot relax their efforts to obtain further funds; and they ask us again to request the members of the profession who have not hitherto contributed to this object to kindly send their donations at once to either of the hon. treasurers (Sir George Burrows, Bart., or Mr. Prescott Hewett), or to either of the hon. secretaries (Mr. George Eastes, M.B., 69, Connaught Street, Hyde Park Square, London, W.; or Mr. W. G. S. Harrison, B.A., Town Clerk, Folkestone), or to pay them into the account of the Harvey Tercentenary Memorial Fund, at the Western Branch of the Bank of England, Burlington Gardens, London, W. Subscriptions from five shillings upwards will be very acceptable.

### NOSOLOGICAL RELATION OF PROGRESSIVE PERNICIOUS ANEMIA.

—A. Wernich (*Deutsches Archiv für Klin. Med.*, Band xx) comments on the great similarity in the symptoms and pathological changes in progressive pernicious anæmia and beriberi, and comes to the conclusion that progressive pernicious anæmia, cachectic dropsy, beriberi, scurvy, and chlorosis belong to a family of constitutional diseases of nutrition.

## ASSOCIATION INTELLIGENCE.

### COMMITTEE OF COUNCIL:

#### NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, London, on Wednesday, the 17th day of April next, at Two o'clock in the afternoon.

FRANCIS FOWKE,

*General Secretary.*

36, Great Queen Street, London, W.C., March 25th, 1878.

### SOUTHERN BRANCH: DORSET DISTRICT.

THE next meeting will be held at Bournemouth, on Wednesday, April 17th, 1878.

The business meeting will be held at the Criterion Hotel, at 4 P.M.

Subject for Discussion: *Post Partum* Hæmorrhage and the Means of Preventing it.

Dinner at 6 P.M. Charge 5s. each, exclusive of wine.

Members intending to be present are requested to notify the same to Mr. NUNN, Maplestead, Bournemouth, on or before April 13th.

WM. VAWDREY LUSH, M.D., Weymouth, { *Hon. Secretaries.*  
C. H. WATTS PARKINSON, Wimborne, }

### NORTH OF ENGLAND BRANCH.

THE spring meeting of this Branch will be held in the Board Room of the Guardians, at Hexham, on Thursday, April 25th, at 2 o'clock P.M.

The following papers, etc., have been promised.

1. Drs. Stainthorpe and Farmer: Case of Aortic Aneurism in a boy aged 13.

2. Drs. Stainthorpe and Farmer: Case of Contracted Knee-Joint, recently operated on by division of the Tendons and Forcible Extension.

3. Dr. Byrom Bramwell: On the Differential Diagnosis of Aortic Aneurisms and other Intrathoracic Tumours, with cases and specimens.

4. Dr. E. C. Anderson: On Lencine and Tyrosine, and their Diagnostic Value in Disease, with cases.

5. Dr. James Murphy: Exhibition of Tarnier's Obstetric Forceps.

6. Dr. James Murphy: On Puerperal Convulsions.

7. Dr. Philipson: Notes of a Case of Hæmaturia.

Dr. J. C. Murray: Case of Difficult Instrumental Labour for Deformed Pelvis.

Dr. M. McW. Bradley: *Post Partum* Hæmorrhage: with notes of three cases successfully treated by compression of the Abdominal Aorta.

Dinner at the White Hart Hotel at 4.30 P.M.; charge six shillings, exclusive of wine.

G. H. PHILIPSON, M.D., *Honorary Secretary.*

Newcastle-upon-Tyne, April 2nd, 1878.

### BATH AND BRISTOL BRANCH.

THE fifth ordinary meeting of the Session will be held at the York House, Bath, on Thursday, April 25th, at 7.15 P.M.: HENRY MARSHALL, M.D., President.

R. S. FOWLER, { *Honorary Secretaries.*  
E. C. BOARD, }

Bath, April 1st, 1878.

### SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.

THE second and last meeting of the twenty first session, 1877-78, was held at Rochester on March 19th; Dr. BURNS, R.N., in the Chair.

The *Honorary Secretary* was re-elected.

*Meetings.*—No place of meeting for next session was appointed, but permission was accorded the *Honorary Secretary* to ascertain the views of members respecting evening meetings for discussion of medical subjects and one afternoon meeting and dinner annually.

*New Members.*—Two gentlemen were elected to the Association, viz.: Dr. Veale, Surgeon-Major, Chatham; and William C. Gasteen, M.B., Surgeon Army Medical Department, Chatham.

*The late Mr. Fry.*—The death of Frederick Fry, Esq., F.R.C.S., of Maidstone, was announced by the Honorary Secretary, and sorrow was expressed by the members present. Mr. Fry was one of the promoters of the district meetings.

*Medico-Ethical Committee.*—Mr. R. I. Nisbett of Gravesend was elected a member of the Medico-Ethical Committee, *vice* Mr. C. J. Pinching, resigned.

*The Balance of Subscriptions* existing in May 1870, when the Branch undertook to pay the district expenses, was ordered to be retained by the Honorary Secretary until further directions.

*Papers.*—The following papers were read. 1. A series of six cases of Acute Necrosis. By A. W. NANKIVELL, F.R.C.S. 1. Boy aged 9; July 16th, 1873; necrosis of both tibiae, of five months' duration; cause—wet by snow; recovery after operation. 2. Girl aged 13; May 1874; necrosis of right fibula, of two weeks' duration; cause—fall; recovery after operation. 3. Boy aged 15; July 25th, 1877; necrosis of right radius, of three months' duration; cause—erysipelas, so-called; recovery after operation. 4. Boy aged 13; November 14th, 1877; necrosis of left leg and knee, of three weeks' duration; cause—fall; amputation for knee-joint disease; recovery. 5. Boy aged 7; January 30th, 1878; necrosis of left tibia, of two months' duration; cause—fall; recovery after operation. 6. Boy aged 9; January 16th, 1878; necrosis of right femur, of seven weeks' duration; cause—wet; recovery after operation, but some dead bone remains for future interference. Mr. Nankivell insisted on the necessity of early diagnosis and of free deep incisions in the first stage.

2. A case of Disruption of the Sacro-iliac Synchondrosis with Displacement of the Sacrum forwards without Fracture, was read by J. THORESBY JONES, Esq.

*Dinner.*—Twelve members and visitors adjourned to dinner at the Bull Hotel.

#### SOUTHEASTERN BRANCH: EAST KENT DISTRICT.

THE sixty-sixth meeting was held in the Council Chamber at Dover on March 21st, 1878; present, Dr. ROBINSON in the chair, and twenty-five members.

*Communications.*—1. Mr. CLEMENT WALTER communicated a case of Hydrophobia.

2. Mr. TEEVAN (London) read a paper on the Importance of an Early Diagnosis of Stone in the Bladder.

3. Mr. WACHER brought forward a case of Foreign Body in the Female Bladder.

4. Mr. COKE related a case of Compound Displacement of the Shaft of the Tibia from its Lower Epiphysis.

*Dinner.*—The members (twenty-four in number) afterwards dined together.

#### YORKSHIRE BRANCH: SPRING MEETING.

THE spring meeting of this Branch was held at the Infirmary, Rotherham, on Wednesday, March 27th, 1878.

*Communications.*—The following communications were read.

1. Dr. SHANN: A Case of Tumour of the Brain.

2. Dr. CLIFFORD ALLEUTT: Cases of Pernicious Anæmia; Case of Pill swallowed into Left Bronchus.

3. Dr. EDDISON: Treatment of Hydatid Cysts.

4. Mr. SNELL: A Case of a Foreign Body imbedded in the Fundus Oculi; Case of a Foreign Body in an Eye for Twenty-nine Years.

5. Dr. THOMAS: A Case of Diphtheria.

6. Mr. KNIGHT: A Case of Tumour of the Fore-arm.

7. Dr. BRAITHWAITE: Two Cases of Inversion of the Uterus; Case of Relaxation of the Pubic Symphysis.

*Dinner.*—After the meeting, thirty-three members dined at the Ship Hotel.

#### SOUTH OF IRELAND BRANCH: GENERAL MEETING.

A GENERAL meeting of this Branch was held in the Royal Cork Institution, on Saturday, March 30th: the President in the Chair.

*The Secretary.*—The following resolutions were passed unanimously.

1. Proposed by Dr. O'FLYNN and seconded by Dr. A. O'CONNOR:

"That, in consequence of the removal of Dr. Ringrose Atkins, our present Secretary, to Waterford, Dr. P. J. Cremen be appointed to act as joint Secretary with him for the Cork district."

2. Proposed by Dr. H. M. JONES and seconded by Dr. P. J. CREMEN:

"That the thanks of the Branch be conveyed to Dr. Ringrose Atkins for the services he has rendered to it in his capacity as Secre-

tary, and for the able manner in which he has discharged the duties of his office; and while we congratulate Dr. Atkins on his well deserved promotion, we desire to express to him our regret at his departure from this city, though we are happy to find that he still retains his connection as Secretary of our Branch."

*Admission of Women to the British Medical Association.*—After a discussion on the subject, a general opinion was expressed adverse to the admission of women to the Association, and to their presence at its meetings.

#### METROPOLITAN COUNTIES BRANCH: GENERAL MEETING.

AN adjourned general meeting of the Metropolitan Counties Branch was held at the house of the Medical Society of London, 11, Chandos Street, W., on Wednesday, March 27th, at 8 P.M.: S. W. SIBLEY, Esq., President, in the chair.

*The Harvey Tercentenary Fund.*—A letter was read from the Committee of the Harvey Tercentenary Fund, asking for the support of the Branch. The PRESIDENT announced that the Council had just voted £10 10s. from the funds of the Branch; and he hoped that the members generally would add their names to the subscription-list.

#### PROVIDENT DISPENSARIES.

The discussion on Mr. Holmes's paper on Provident Dispensaries, adjourned from the meeting held on February 27th, was resumed.

The PRESIDENT gave a brief summary of the proceedings of the previous meeting; remarking that what was most desired was information as to the practical working of provident dispensaries.

Mr. HOLMES moved the following resolutions:—

"1. That, in the opinion of this meeting, no patients ought to be admitted gratuitously at the out-patient departments of hospitals, except for medical reasons, shown by the recommendation of the patient by some medical authority.

"2. That the wage-earning classes, who are above the necessity of gratuitous out-patient relief under the Poor-law, would obtain more efficient medical attendance by paying the proper subscription to a provident dispensary than they now have at the free out-patient departments of hospitals.

"3. That, if freed from the competition of the free hospitals and dispensaries, provident dispensaries might be founded in London, on principles fair both to the patients and to their medical attendants.

"4. That the out-patient departments of public hospitals might be connected with the institutions charged with the medical care of the working classes, with great advantage to the public health and to medical education."

He said that what was wanted was not so much a discussion on general principles, regarding which there was much agreement, as information with regard to the practical working of the dispensaries, and to any amendments that might be necessary.

Dr. GRIGG seconded the resolutions.

Dr. BURNEY YEO proposed as an amendment to the first, second, and fourth resolutions—

"That this meeting is of opinion that, in hospitals to which medical schools are attached, the cases of all applicants for admission as out-patients should be submitted to a preliminary investigation by a competent medical authority, who should determine, exclusively on medical grounds, whether the cases were suitable for admission to the out-patient department of the hospital in question or whether they should be referred to a poor-law or a provident dispensary."

He agreed with much that had been said by Mr. Holmes in his paper, and was not opposed to the formation of provident dispensaries; but he objected to their proposed relation to the hospitals and medical schools. How was it that the gentlemen engaged in the out-patient departments of the hospitals had not been found willing to co-operate in the provident dispensary movement? The answer was not difficult. There had been a tendency to exaggerated statements as to the way in which the out-patient work was done. Mr. Holmes had spoken of the advice given in the out-patient departments as being hurried and worthless. Dr. Gairdner of Glasgow had stated that, in some hospitals in London, five, three, or two minutes was all the time that could be given to the investigation of a serious case. He could not help thinking that such erroneous statements had been gathered from the publications of the promoters of provident dispensaries. He had been for some years engaged in out-patient work, and, from the observations which he had made, he believed the statements of Dr. Gairdner and Mr. Holmes to be quite inconsistent with fact. Could it be supposed that the medical officers of the out-patient departments were men

capable of making blind guesses and writing useless prescriptions? No men in the profession did their work more conscientiously. Another exaggeration was as to the class of patients who attended the out-patient rooms. He could not comprehend the statements which had been made, that ladies went to the hospitals in their servants' dresses in order to get advice, this advice being declared to be worthless. Where was the information gained? Supposing that some persons who could possibly pay for medical advice did attend the hospitals, the circumstances to which they would have to submit must be considered—having, for instance, their chests percussed by several athletic students. The proposed connection of provident dispensaries with the general hospitals was impracticable. Either the out-patient departments must be made into provident dispensaries; or the lay and medical managers of the hospitals must be asked to allow an important department to be under the direction of persons over whom they had no control. Mr. Holmes had said that the connection of provident dispensaries with the hospitals would give the students opportunities of visiting the patients at their own homes. But they would not do so unless compelled to do so by the regulations of the examining boards. Very great difficulty was found in getting students to attend midwifery cases beyond the number required for their certificates. In every hospital, there should be a well qualified paid medical officer who should examine all applicants, selecting those fit for the out-patient department, and directing those who were unfit as to the manner in which they might obtain advice at provident or poor-law dispensaries.

Mr. S. S. ALFORD seconded the amendment *pro forma*. He had had twenty-eight years' experience of the working of provident dispensaries, and would give the results of his observations. At Haverstock Hill, there was a successful provident dispensary which had been established thirteen years, numbering nearly five thousand members. Four medical officers were now connected with it. The management was in the hands of a committee elected from the honorary subscribers, and including the medical officers *ex officio*. The free members paid 4d. a week for a family including husband and wife and all children under fourteen, with another 1d. a week for all above fourteen. For each confinement, 15s. was paid, to which 5s. was added from the honorary fund. Wives might join with their families if their husbands belonged to a club for 3d. a week; widows and single women paid 1d. a week; single men above eighteen 1½d. a week. No free members could obtain medical treatment until three months after admission, unless they paid an entrance fee of 5s. and three months' subscriptions. The resident dispenser also acted as assistant-secretary, receiving the payments and keeping the books. The honorary fund, amounting to about £230 a year, paid for the rent, dispensers' and porters' salary, printing, and all incidental expenses. The payments of the free members, which amounted in 1877 to £732, including £107 for midwifery, were devoted to the payment of the drugs, the remainder being divided amongst the medical officers. It was intended to pay for quinine and cod-liver oil from the honorary fund; but it had not been sufficient. In 1876, £575, and in 1877, £648, was divided amongst the then three medical men, besides £8 to the midwife. The working classes largely availed themselves of the dispensary. Mr. Alford gave a short history of the origin of provident dispensaries in his neighbourhood. In 1849, a dispensary was established with the assistance of the late Mr. Smith of Southam, the father of provident dispensaries; but it failed through the opposition of the supporters of a free dispensary in the neighbourhood, and from the secession of several of the medical attendants. In 1865, a provident dispensary was again started, and its success justified the expectations formed. Last year, one of the medical men received £275 as his share. Efficient management was very important; correctness in receiving the numerous small payments, and keeping a close supervision on these payments, was essential to success. How far provident dispensaries and hospitals could be got to work together, by sending the worst and most marked cases to the hospital in these days of intelligent general practitioners, it was difficult to see. He was sure that well managed provident dispensaries were certain to succeed. They would have an elevating influence on the working classes; and would well pay the medical man. With proper care, none need be allowed to join who ought not to do so, and thus the general practitioner would not be injured; certainly, his books would be freed somewhat from bad debts. In the Haverstock Hill Provident Dispensary, the free members were limited to persons receiving less than 30s. a week; this had since been raised to 40s. in consideration of the increased price of provisions, etc. By the establishment of provident dispensaries, the working classes would secure prompt and efficient medical attendance; good drugs; no time would be wasted by waiting at hospitals; they would suffer no degradation in taking what they could well pay for; and above all, would have no long doctors' bills and county court summonses and judgments hanging

over their heads. Therefore, as a real benefit to the working classes, and no loss, but a positive gain, to the medical profession, he strongly recommended the establishment of provident dispensaries.

SIR CHARLES TREVELYAN wished to make a few observations. The out-patient departments of hospitals had been formed in order to provide for the medical treatment of the people. He understood, however, that the increased attendance led to expenditure of the strength of the patients through delay in the waiting-rooms, the communication of infectious diseases, and want of sufficient time to attend properly to each case. The congestion of the department must be diminished; and it had to be considered on what principle this should be done. The first idea was that a classification should be made according to the pecuniary circumstances of the applicants; but further consideration showed that it must be on medical grounds. Hospitals were intended for serious cases; while less severe illness should be provided against by persons as a part of their ordinary expenditure, so that they might be attended at provident dispensaries in their neighbourhood, or at their own homes, where ample time could be given for investigation and they might select their medical attendants. The beneficial influence of the presence of medical men in the homes of the people would be inestimable. There had been a movement in favour of trained nurses. This might become only another means of pauperising; but if the nurses were connected with provident dispensaries, the work could be done efficiently without leading to pauperism. A provident dispensary was like an assurance institution, except that the advantages were received during life instead of after death. Their advantages to medical men were that small accounts were avoided, and no bad debts contracted. As to actual payments, they were very liberal at Northampton, Derby, and some other places; at Camberwell, in 1876, they amounted to £819; at Haverstock Hill to £648 in 1877; at the Royal Pimlico Dispensary to £369 in 1876. If the system had fair play, the amount would be much greater. The clubs were an imperfect and crude form of provident dispensaries; they excluded women and children, who required care of their health even more than the men. The most perfect example of the junction of the provident system with a general hospital was presented by the Royal Albert Hospital at Devonport. Dr. Nankivell had succeeded in getting the provident system adopted in the Torbay Infirmary; and the same thing had been done in West Bromwich, Guildford, and other towns. In London, there were three provident dispensaries in the neighbourhood of St. George's Hospital. Each hospital in London should be the centre of a system of provident dispensaries, sending to them the trivial cases and receiving in return the more important ones. The medical officers of each general hospital should be the consulting officers to all provident dispensaries in the district. It was not necessary that the hospitals and the dispensaries should interfere with each other; they might work in co-operation. With regard to the charge of exaggeration raised by Dr. Yeo, numerous medical men had expressed dissatisfaction at being obliged to attend to the patients in a perfunctory way. He had also been long ago informed of cases in which persons who could well afford to pay attended the out-patient departments. He thought Dr. Yeo's amendment unnecessary.

Dr. JOSEPH ROGERS said that Dr. Yeo's statement as to the manner in which the duties of the medical officers were performed could not be correct, if the figures given each year as representing the number of patients attended in the hospitals were to be relied on.

SIR RUTHERFORD ALCOCK said that the subject under discussion was one in which he had taken much interest. Dr. Yeo's statements had been very effectually met. As to provident dispensaries, there were two great difficulties. There was the danger of receiving patients who could pay their medical men; and, on the other hand, many went to gratuitous dispensaries who ought to go to provident dispensaries. It was difficult to steer between these two difficulties. The amount of wages was a very uncertain guide. A man earning thirty shillings a week, and having a sick wife, was as much an object of charity as one who had twenty shillings without such incumbrance. The great question was, whether the out-patient departments of hospitals were overcrowded, and whether the poor had proper attendance in the hospitals. He must say that the argument was much against the present hospital system. It was not possible to attend to a patient in one or two minutes. There was a general complaint that the number of patients was too great for the medical officers. He did not think that the medical officers of hospitals ought to be expected to spend their time in seeing fifty or more trivial cases in a day. The medical profession had a strong interest in having the system readjusted on a better principle. Instead of the hospitals and provident dispensaries being antagonistic, their co-operation would conduce to the benefit of the patients.

Mr. H. C. BURDETT spoke of the sums divided among the medical

officers at some of the provident dispensaries. In Manchester, in 1874, fifty medical men divided £2,000 raised from 100,000 members. In Northampton—where the limitation of the staff created some dissatisfaction among other members of the profession—nearly £2,000 had been divided in one year among three medical men, one of them receiving as much as £1,200. As to Dr. Gairdner's statements, no doubt he had a foundation for them. At St. Thomas's Hospital, under a system of selection, the number of cases in a year had been in three years reduced from 60,000 to 20,000. His view was that the additional 40,000 must be put down as trivial cases, or casualties. At Guy's Hospital, the applicants were examined first by the house-surgeon, and this year one-half of those applying as out-patients had been rejected. Would it not be possible to combine the resolutions and the amendment? Without unanimity, it would be impossible to get a system that would work. He would suggest a conference of the representatives of provident dispensaries and of hospitals, and the appointment of a joint-committee from both sides, who might consider Mr. Holmes's proposals. The plan which had been followed in Manchester since 1873 was a valuable one. Severe cases were sent from the provident dispensaries to the infirmary; and, instead of the provident dispensaries interfering with clinical teaching, the Manchester School of Medicine had risen to the first place among the provincial schools. He wished that the provident dispensaries could altogether wipe out the free dispensaries; the latter encouraged improvidence by the way in which tickets were issued.

Dr. SHRIMPTON thought that the object of the nursing association had not been understood. He believed that it was capable of rendering great service to the provident dispensaries, by supplying nurses who could be called on by the medical men to attend the patients of these institutions just as in the case of private patients. The promoters of the nursing association were anxious to act with all existing institutions, and to enable the nurses to live on their own resources.

Mr. JABEZ HOGG thought that the abuse of the out-patient departments must be admitted by all who had had experience of it. It was impossible for the medical officers to do their duty; and the reason why so few of them acted with the promoters of provident dispensaries was that, if they did so, they rendered themselves obnoxious to the managing bodies of the hospitals. In twenty-seven years' practice at an ophthalmic hospital, he had often met with patients who were able to pay: for example, an owner of house property and the manager of a provincial bank. In the Dispensary for Skin-diseases, managed for many years by Mr. Hunt, the patients never objected to pay one or two shillings.

Dr. R. LEE said that an important question was the extent to which the interests of general practitioners would be affected by the provident dispensaries. The only speaker on this subject had been Mr. Alford, who was strongly in favour of provident dispensaries.

Dr. MORTON said that, unless care were taken, the provident dispensaries might do serious injury to general practitioners. This, however, might be obviated by care. His experience in the working of a provident dispensary had been not so successful as that of Mr. Alford: the dispensary had been successful; but this was due mainly to the honorary subscriptions. Unless it were self-supporting, there would be great difficulties.

Mr. G. BROWN considered the provident dispensary system worthy of the support of general practitioners.

Mr. PARAMORE had been told by a friend, that he had suffered injury through the establishment of the provident system in the Royal Albert Hospital at Devonport.

Mr. HOLMES having replied, Dr. VEO withdrew his amendment, and the original resolutions were passed *unanimously*.

## CORRESPONDENCE.

### DO MEDICAL MEN PROMOTE INTemperance?

SIR,—Permit me to invite the attention of the profession to a charge which is being persistently brought against us by temperance advocates in their speeches. I take an interest in the Church of England Temperance Society, and have, on several occasions, been present at meetings intended to forward its objects in my own immediate neighbourhood and elsewhere.

At such meetings, I have heard speakers—men of station, education, and influence—attack the medical profession, without limitation, as promoters of intemperance among the poor by the reckless prescription of alcoholic stimulants for trifling ailments. While recently on a visit to some friends in a western county, I was requested by the parish clergyman to attend a meeting of his parishioners convened to establish

a branch of the Church of England Temperance Society. The meeting was well attended by all ranks, and was considered a success by those who organised it. But, as usual, "the doctors" came in for censure as promoters of intemperance. I said what occurred to me on the spur of the moment in defence of my profession, and, on the following day, in letters addressed to the principal speakers, I challenged the accuracy of their imputations. I pointed out that the use of alcohol in disease is one of the most difficult and delicate questions in a difficult and delicate art; that it is not to be settled by platform jokes and cheap sneers, which, however adapted to raise ignorant laughter and applause, are not likely to influence the practice of medical men; further, that the speakers have not, in the course of daily duty, to stand at the bedside, finger on a faltering pulse, to decide the often life or death question of stimulants or no stimulants. And I ventured to dwell on the impolicy of causing irritation in the minds of medical men by such unqualified attacks, thus running the risk of disgusting them, and preventing them from supporting a movement directed against a vice better known to them in its terrible results than to any other class in the community. My remonstrances were taken in good part; but, while they did not deny that alcohol might be judiciously used in the treatment of disease, my correspondents firmly but courteously insisted that many practitioners do largely encourage intemperance by the thoughtless manner in which they order stimulants, giving me the assurance that, in numerous instances within their own knowledge, re-claimed drunkards were in this way led to return to their old habits.

I was led, in consequence, on my return home, to put myself in communication with many earnest workers among the intemperate, and found that one and all of them, rightly or wrongly, make the same complaint. We all know that, among people far removed from the poor in station and circumstances, we meet with intemperate men and women, who, when remonstrated with by their friends, do often most falsely blame their doctors for their excesses. I have had abundant evidence of this at home and abroad; and there is much reason to believe that the same excuse is often just as falsely pleaded by the poor. Making due allowance for a reasonable proportion of such cases, is there still ground for this serious charge, so persistently made against a not inconsiderable number of practitioners of unintentionally, but not less certainly, promoting intemperance in the manner indicated above? I cannot answer the question. But I think it is time an answer should be forthcoming; for the charge is being daily made. Once more, I invite attention to the fact that the charge comes not always from vulgar and intemperate fanatics, but, as I can testify, from men of station, intelligence, and experience, who say of us that we are responsible for this evil.—I am, sir, your obedient servant,

Netley, April 5th, 1878.

W. C. MACLEAN, M.D.

### HOSPITAL FINANCE.

SIR,—I notice with great pleasure a suggestion in the JOURNAL of April 6th from Mr. Custance for a conference of hospital managers. I trust this suggestion will attract the attention it deserves. Mr. Custance is thinking mainly, if not exclusively, of the question of hospital finance. But there are other subjects also which such a conference would be peculiarly well employed in discussing, such as the out-patient question, which is now engaging the attention of a committee of the Association, of which I am chairman. We are continually met by the difficulty that the reform which we believe to be wanted in that direction cannot be made without the co-operation both of the lay and medical members of hospital administrations. Now, these two elements have hitherto been kept far too much apart. There are questions, such as that of medical teaching, which, though of the greatest public importance, are relegated entirely to the medical man; and others, such as the finance and general administration of the hospital, which, though of the greatest medical importance, are regarded as the exclusive province of laymen. If there were some general body in which both could freely mingle, and where all hospitals, great and small, with schools and without, would be represented, I am persuaded that more enlightened views would prevail on subjects of hospital management as well as on that of hospital finance. Meanwhile, the general question of the uses and abuses of hospitals, and of the application of the great revenues spent on hospitals, is coming more and more into public notice, and the idea of a formal inquiry into the whole matter either by a Royal or Parliamentary Commission is becoming familiar to people's minds. In such a contingency also, a common deliberative body which would in some degree secure the adequate representation of all the interests affected would be most useful.—I am, sir, yours, etc.,

T. HOLMES.

18, Great Cumberland Place, Hyde Park, W., April 9th, 1878.

## TEACHING OF PHYSIOLOGY IN DUBLIN.

SIR,—Your remarks on Dr. Harvey's letter show that the whole facts were not before you, and, as a member of the College of Surgeons' Council, who opposed the acceptance of his certificate for practical physiology, I feel bound to supply them. The by-law enacts that the lectures on anatomy and physiology shall be given during the winter session and on five days weekly, and surely a certificate of thirty meetings of the class during summer was clearly inadmissible under it.

Up to 1874, a course of operative surgery was occasionally taken instead of a third course of lectures, the candidate showing that he was unable to present a certificate for the latter. This was done by special vote of council, which any one member could have nullified. Since the performance of operations on the subject is required of every pupil during the surgical courses, and of every candidate for the diploma, I believe the substitution referred to has not been allowed. The Council is certain to seek the permission of the Secretary of State to modify the by-law so as to require only two courses of physiology and less than five lectures weekly, which number was fixed when anatomy formed much of the business.

For the teaching of physiology, lectures on three days and a meeting of the class for practical instruction on a fourth, during each of twenty-one weeks, seem to me sufficient, if a few days at the end of the session be also devoted to the work of the students themselves.

During the second winter's course, some new matter will surely be introduced, and the rest will be impressed on those who have attended before. Besides, in a large class, there will always be many who, from want of previous training, or from unavoidable occasional absence, have missed much instruction during the first session.

The principles of the science can be most advantageously taught during the same session, with the practical work of which histology forms the greater part. To carry on the latter in summer exclusively would leave the winter's talk about physiology dull and profitless indeed. According to the *Medical Directory*, 1878, practical physiology is exclusively a winter course in all the great English and Scotch schools, except the University of Glasgow.

Dr. Harvey's assertions that the Council of the College "show a distinct determination not to allow the introduction of practical teaching into Dublin", and that "medical teaching in Dublin is in a very unhealthy condition", are regarded as unfounded and unbecoming, and deserving of much stronger terms, if the object of his communication were to represent that the courses of instruction in the other schools were inferior to those given in the school of which he is one of the owners.—Yours faithfully,

E. D. MAPOTHER.

6, Merrion Square N., April 8th, 1878.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

VACCINATION.—Mr. R. Bryden of Uffculme, Devon, has received £9:10 from the Local Government Board for successful vaccination. This is the second grant which has been awarded to him.

## POOR-LAW GUARDIANS AND MEDICAL OFFICERS.

SIR,—As a general thing, it is better for all parties concerned that the Boards of Guardians and the Poor-law medical officers should work in harmony with each other. Only thus can the work of the Guardians, in as far as the medical care of their poor is concerned, be efficiently performed. But if many such cases arise as that described by your correspondent signing himself "Ruffled" in the *BRITISH MEDICAL JOURNAL* of March 23rd, then we say distinctly that the much-to-be desired harmony is at an end. As your correspondent justly observes, "Breach of faith towards medical officers makes all public (medical) services unpopular." We go further: it tends to put an end to them altogether. But there are certain well understood conditions on which a Poor-law medical officer acts, which distinctly form part of the engagement entered into betwixt the Guardians and him when he agrees to attend the Board's poor. One of these conditions is, that the usual "extras" be paid by the Board; and to this that body is as much bound as he is to attend its poor, properly sent to him with the usual order, as soon as possible in reasonable hours. The question comes to be, What are those "extras" to be so paid for by the Board? Flooding, as complicating labour, with the fetus at any stage of development, is clearly one of those "extras", provided the patient attended is a pauper. In the interest of humanity such cases are attended at once, the person procuring the order (on the faith of getting which the doctor attends) after the danger has been attended to. And this brings us to the question, Who is a pauper? Now, in point of fact, all our agricultural population are, even when in receipt of full wages, so treated by the Boards in ordinary cases of illness, when the Boards have nothing extra to pay to their medical officers; and that fact constitutes them paupers should the necessity for medical attendance arise, when the "extra" fee falls to be paid. Thus, if the patient attended by your correspondent have been previously sent to him as a pauper, presumably at the Board's direction and with its full knowledge, then the Board itself has established the fact of his being a pauper, and the medical officer is entitled to any extra fee that may fall due. He

is equally so entitled should the patient belong to the class usually sent as paupers; or if—the circumstances of the patient remaining the same—the medical man be called on at a later date to treat him on the Guardians' account. Further, it is not your correspondent's duty to provide a pessary, otherwise than at the Board's expense. The poor are the Board's special charge, not his. He might as well be called on to provide wine or beef-tea.

Lastly, no contract violating the law of the land is other than faulty. The Boards could scarcely be allowed to "be a law unto themselves"; they are simply parties to a contract made under certain conditions—one of which is, that good faith shall be observed.—I am, etc.,

F.R.C.S.Ed.

## PUBLIC HEALTH MEDICAL APPOINTMENTS.

\*WILSON, Thomas, M.R.C.S.Eng., appointed Medical Officer of Health for the Wallsend-on-Tyne Urban Sanitary District.

## REPORTS OF MEDICAL OFFICERS OF HEALTH.

CHAILEY.—The birth-rate in this rural district in 1877 was calculated at 34 and the death-rate only 15 per 1,000 inhabitants. Small-pox was introduced by a tramp, who was taken into the workhouse infirmary, where he died. Five cases occurred almost simultaneously amongst the inmates of an adjoining ward, and is supposed by Mr. Gravely to have been "conveyed through the medium of the chimney-flues". Other cases occurred in a cottage; but the disease did not spread, as the sick were strictly isolated. As several deaths from hydrophobia occurred in the district, the medical officer advised his authority to publish such information as was likely to check its spread.

EPPING.—There were 644 births and 351 deaths registered during the year, the birth-rate being equal to 29.1 and the death-rate 15.8 per 1,000. The zymotic death-rate was 1.4 per 1,000. Mr. Fowler says that several cases of small-pox were brought into the district; but the disease did not spread, except in Loughton. The infantile mortality was moderate, viz., 11.3 per 100 births for the whole district; but in Epping it was only 8.4, whilst it was 17.7 in Harlow and 13.4 in Chigwell. Sanitary work was fairly carried out, as the sanitary inspectors made 861 and Mr. Fowler 50 inspections during the year. Erysipelas has been prevalent, especially in Loughton.

## MILITARY AND NAVAL MEDICAL SERVICES.

## THE ARMY MEDICAL SERVICE.

SIR,—I have read with pleasure your statement of the grievances affecting the officers of the Army Medical Department. They may be summarised as treatment unjust, inconsiderate, and exceptional. It is an error to imagine that a service can be rendered popular by holding out alluring baits to recruits in the shape of bounty. Contentment or discontent percolates, slowly but surely, from the seniors downwards, and stamps with the profession at large the character of the service. Let the aspirant to the Army Medical Department see before him a life career, with an assured provision for his later years—not of 19s. 10d. a day, as at present in the executive ranks, after a service of from twenty-five to thirty-five years, but of £1 a day after twenty years, rising by annual increment for further service, until he is placed on half-pay from age or infirmity. The administrative grades must be, to the majority, an impossibility, but the pension of the deputy surgeon-general should be increased. The difference between it and that of the surgeon-general is ridiculous. The retiring allowance itself is quite out of proportion with that of similar ranks in other departments. Were these important measures taken, and some matters of detail—which any capable administrator could easily grasp—attended to, with a desire to render the service popular, I have little doubt that the present difficulty of obtaining candidates would soon disappear.—I am, etc.,

COMMON SENSE.

## SERVICE UNDER THE NEW ARMY MEDICAL WARRANT IN INDIA.

SIR,—Will you allow me some space in your *JOURNAL* to call attention to the following points with regard to the above, which, so far as I know, have been hitherto unnoticed? The Warrant states that surgeons will get pay amounting to £250 *per annum*, with allowances, during their period of service, which is limited to ten years. This is all very well at home; but now let us look across the water as to how we fare in India. Thirty-three surgeons entered the service immediately after the new Warrant came into force. Their commissions were dated February 4th, 1877, after they had passed through Netley, instead of being antedated to the 30th September, 1876, the time of their entering Netley, as was done with all surgeons who had entered previously, thus depriving the latter surgeons of four months' seniority. After seven months' service at home, some of them were sent out to India, and during the following three months all had been sent out with the exception of one, who was sent to Hong Kong, and another who is at present on sick-leave at home.

In India, the Warrant states that "the rates of pay will range from 317 rupees (£31 14s.) to 433 rupees (£43 6s.) per month, according to length of service". From this statement, of course we inferred that on first going out to India we should get pay amounting to the equivalent in rupees of £31 14s., and this would have been an increase of about £6 per month upon our pay and allowances while at home (the latter amounting to £25 11s. 10d. per month). But instead of getting an equivalent of £31 14s., we only get 317 rupees per month, which, on account of their present depreciation in value, represents £25 14s. 9d. per month; thus our increase of pay for serving in India amounts to £2s. 11d. per month, whilst former surgeons and other ranks in the service get almost double their home pay. The 317 rupees per month is exactly the same pay that the old assistant-surgeons got, and that surgeons serving under former Warrants get. The reason of this discrepancy is stated to be that the Indian Government refuse to recognise our right to increase of pay under the new Warrant. Now, if a surgeon enter the service who, perhaps, has

other calls on him besides merely providing for himself, I think he is bound to act on the supposition that he shall be turned out at the end of ten years with a bonus of £1000; therefore it behoves him to try and save something out of his pay so as to add to that bonus. This, though perhaps possible at home (if he have only himself to provide for), is certainly impossible in India, on account of increased expenses. He must keep a horse, he must employ at least five servants, he may even be obliged to provide himself with a tent, etc.; add to this, that nearly all articles in common use are more expensive as well as messing, etc.; and in this country we must remain five years, unless invalidated home during that period. If the latter calamity occur, provision is made that "at the discretion of our Secretary of State for War he may be granted half pay at a rate not exceeding £8. *per diem* if he have served five years or more, or £8. *per diem* if he have served less than five years for a period not exceeding six months at a time. If at the expiration of six months he be unable to resume duty, a further period of six months will be allowed *without pay*; at the expiration of which time, if still unable to resume duty, his services shall be dispensed with. These conditions as regards sick-leave might surely be ameliorated; and, in all common fairness, we ought to get 3s. 6d. *per diem* in addition to the 317 rupees per month we are now getting in India—viz., the difference between our home pay and the former surgeons' home pay—our home pay being 13s. 8d. *per diem*, and theirs being 10s.

As far as pay goes, the present Warrant is an improvement on former ones, provided the surgeon serves at home; but as at least the greater part of his service will be in India, he is worse off than he was before, as he was then serving towards a pension, while at present he is not.—I am, sir, yours, etc.,  
PERICK.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Board of Examiners, on April 4th; and, when eligible, will be admitted to the pass-examination.

Messrs. Octavius A. Collins, William T. Wyatt, G. W. Hamilton Cumming, Ernest Clarke, William J. Collins, and Henry R. Spackman, students of St. Bartholomew's Hospital; Thomas W. L. Beales, Dudley C. Trott, R. J. Herbert Scott, and L. W. Kinglake Phillips, of Guy's Hospital; Ebenezer D. Evans, James C. Marsden, and Henry Maudsley, of University College; Marmaduke Pittard and J. Barrington Baker, of the Charing Cross Hospital; John Thomas and W. Woolmington Webber, of St. Thomas's Hospital; J. J. Edward Renshaw, of the Manchester School; J. MacDonald Rogers, of the Middlesex Hospital; H. C. Rudolph Burn, of St. George's Hospital; and C. Graham Havell, of St. Mary's Hospital.

The following gentlemen passed on April 5th.

Messrs. Charles D. Davis, A. Osborne Knight, and Mark Jackson, of the Middlesex Hospital; Robert Heeles, T. Percy Woodhouse, and R. Isherwood Williamson, of St. Thomas's Hospital; U. A. Carpenter Harris, W. G. Augustus Bedford, and John Wilson, of St. Bartholomew's Hospital; Herbert G. Ashwell and John W. Sanders, of Guy's Hospital; E. A. Haden Horsley and H. Monague Murray, of University College; George C. Gandin and William H. Hiddings, of St. George's Hospital; William G. Evans and H. Sullivan Parker, of King's College; Henry W. Pomfret, of the Manchester School; J. P. Budgett Wills, of St. Mary's Hospital; Thomas G. Stonham, of the London Hospital; W. Jenner Clarke, of the Charing Cross Hospital; and Deane Bennett, of the Charing Cross and St. Mary's Hospitals.

The following gentlemen passed on April 8th.

Messrs. Alfred Hoare, Charles A. Weber, Heaton C. Howard, and F. D. Caesar Hawkins, of St. George's Hospital; Sidney H. Lyndeman, William T. M. Clark and Henry J. Towson, of St. Bartholomew's Hospital; Henry W. P. Makeham and William H. F. Jones, of the London Hospital; Charles R. Crane, of the Charing Cross Hospital; Christopher J. Watkins, of University College; Kenneth W. Millican, of St. Mary's Hospital; Edward A. Starling, of Guy's Hospital; Charles S. Sherrington, of St. Thomas's Hospital; William A. Morris, of King's College; Peter F. Sturridge, of the Middlesex Hospital; and Richard Honeyburne, of the Liverpool School.

The following gentlemen passed on April 9th.

Messrs. G. Hutchinson Milnes, Charles J. Marsh, Norman McB. Reid, and C. Bradley Maitland, of St. George's Hospital; Dudley W. Buxton, Henry R. Gayley, and Denis W. Donovan, of University College; William H. Quicke and Charles W. Glassington, of the Westminster Hospital; George L. Galpin, of the Middlesex Hospital; William Renne, of the Liverpool School; Robert Maguire, of the Manchester School; and John Phillips, of the Cambridge School.

Twenty-six candidates out of the one hundred and sixty-two examined, having failed to acquit themselves to the satisfaction of the Board, were referred to their anatomical and physiological studies for three months.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 4th, 1878.

Claremont, Claude Clarke, Millbrook House, N.W.  
Evans, James William, Trevaughan, Carmarthen  
Green, Albert Edward, Ashford Terrace, N.  
Green, Charles, Eston, near Middlesborough  
Matthews, Valentine, 35, Southampton Street, Strand  
Oxborn, William Henry, Wheelley's Road, Birmingham  
Robins, Harvey, Park House, Notting Hill  
Swann, Alfred, Manningham, Yorkshire  
Wells, Alfred George, Cross Street, Horselydown, S.E.

The following gentlemen also on the same day passed their primary professional examination.

Hare, Evan Herring, St. Thomas's Hospital  
Hawkins, Walter Robert Thomas, London Hospital

Prince, Herbert, Charing Cross Hospital  
Shapley, Frank, London Hospital  
Steele, Warwick Charles, St. Bartholomew's Hospital

## MEDICAL VACANCIES.

The following vacancies are announced:—

**ABBEYLEIX UNION.**—Apothecary for the Workhouse. Salary, £40 per annum. Election will take place on the 16th instant.

**ASHTON-UNDER-LYNE DISTRICT INFIRMARY.**—House-Surgeon. Salary, £80 per annum, with board and lodging. Applications to be made on or before the 17th instant.

**BOURNEMOUTH GENERAL DISPENSARY AND COTTAGE HOSPITAL.**—Resident Medical Officer. Salary, £120 per annum, with rooms, coals, gas, and attendance. Applications to be made on or before the 18th instant.

**BRISTOL GENERAL HOSPITAL.**—Physician's Assistant. Salary, £50 per annum. Applications on or before the 19th instant.

**EASTERN DISPENSARY OF BATH.**—Resident Medical Officer. Salary, £100 per annum, with furnished apartments, coals, gas, and servants. Applications to be made on or before the 16th instant.

**ENNIS DISTRICT LUNATIC ASYLUM.**—Resident Pupil. Applicants must be qualified as Physician and Surgeon, and not above thirty years of age. Salary, not less than £50, or more than £60 per annum, with apartments and rations.

**GERMAN HOSPITAL, Dalston.**—Honorary Assistant-Surgeon. Applications to be made on or before May 1st.

**KENT and CANTERBURY HOSPITAL.**—Assistant House-Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing. Applications to be made on or before the 25th instant.

**NARBERTH UNION.**—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.

**QUEEN'S HOSPITAL, Birmingham.**—Honorary Physician. Applications to be made on or before the 13th instant.

**ROSCOMMON INFIRMARY.**—Resident Apothecary and Registrar. Salary, £60 a year, apartment, rations, fuel; or a Non-resident Apothecary to compound the medicines at £30 a year; and a Registrar at £30 yearly. Applications to the 17th instant.

**ROYAL CORNWALL INFIRMARY.**—House-Surgeon, Secretary, and Dispenser. Salary, £200 per annum, with furnished rooms, coals, gas, and attendance. Applications to be made on or before the 24th instant.

**TOWCESTER UNION.**—Medical Officer and Public Vaccinator for the Blakesley District. Salary, £60 per annum, and fees. Applications to be made on or before the 22nd instant.

**TRALEE UNION.**—Medical Officer for Brosna Dispensary District. Salary, £100 a year as Medical Officer, and £20 per annum as Sanitary Officer, with the usual Registration and Vaccination Fees. Applications to the 20th instant.

**WARNEFORD, LEAMINGTON, and SOUTH WARWICKSHIRE HOSPITAL.**—House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before the 16th instant.

**WESTMINSTER HOSPITAL.**—House-Physician and House-Surgeon. Applications to be made on or before the 20th instant.

**YORK DISPENSARY.**—Resident Medical Officer. Salary, £130 per annum, with furnished apartments, coals, and gas. Applications to be made on or before the 18th instant.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

**AMPLETT, Edward, M.A., M.B.,** appointed Assistant-Surgeon to the Charing Cross Hospital, *vice* \*E. Bellamy, F.R.C.S., appointed Surgeon.

\***BROWN, Charles R., M.D.,** appointed Honorary Physician to the All Saints' Convalescent Hospital, Eastbourne, *vice* Arthur Whitehead, Esq., deceased.

\***BRUNTON, John, M.A., M.D.,** appointed Honorary Consulting Surgeon to the Royal Caledonian Asylum, *vice* Sir William Ferguson, Bart., deceased.

**CANTLIE, James, M.B.,** appointed Assistant-Surgeon to the Charing Cross Hospital, *vice* R. Godlee, F.R.C.S., resigned.

**PIEDCOCK, G. D., B.A. Cantab.,** appointed Assistant House-Surgeon to the Cumberland Infirmary, Carlisle, *vice* J. W. Hinings, M.R.C.S., resigned.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

### BIRTHS.

**BARNES.**—On April 7th, at 45, Lowther Street, Carlisle, the wife of \*Henry Barnes, M.D., of a son.

**MOORE.**—On April 9th, at 40, Fitzwilliam Square West, Dublin, the wife of \*John William Moore, M.D., of a daughter.

**WATSON.**—On April 5th, at Tottenham, the wife of \*W. Tyndale Watson, M.D., of a daughter.

### DEATHS.

**MACAW, Kennedy, M.D.,** Surgeon-Major, aged 37, on April 9th.

**MACLAGAN.**—On April 6th, at 14, Melville Street, Edinburgh, aged 88, Jane White-side, widow of David MacLagan, M.D., F.R.S.E., Physician to the Forces, and Surgeon-in-Ordinary to the Queen for Scotland.

**THE WIGAN INFIRMARY** will receive the sum of at least £150 as the result of the exhibition of pictures painted by Captain Charles Mercier.

**DONATION.**—The Rev. Arthur Pakenham has given £200 to the Belfast Royal Hospital, in remembrance of his brother, Lieutenant-Colonel Pakenham; making, with previous contributions, the sum of £1000 towards the funds of this institution.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY ....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.**—Medical Society of London, 8.30 P.M. Mr. Owen, "Two Cases of Wry Neck"; Dr. Drysdale, "On Syphilis as a cause of Aphasia and Locomotor Ataxy".

**TUESDAY.**—Pathological Society of London, 8.30 P.M. Diseases of the Lymphatic System (concluded). Specimens by Dr. Hoggan, Mr. Porter of Netley, Drs. Kesteven, Turner, Dickinson, and Garlick. Also, by Dr. Dickinson: Ulceration of the Bowel in connection with Granular Kidney. Dr. Ord: 1. Renal Calculi of mixed Carbonate and Phosphate; 2. Specimens of Spontaneously Disintegrated Calculi.

**WEDNESDAY.**—Association of Surgeons Practising Dental Surgery, 8.30 P.M. Ordinary Meeting.

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**DR. ABRATH'S** (Sunderland) communication arrived on Thursday afternoon, as the *JOURNAL* was being made up for press. It shall have attention next week.

**ERRATUM.**—In the *JOURNAL* for March 2nd, page 297, column 2, line 6, for "one hundredth of a grain", read "one-twentieth of a grain".

**MILITIA.**—The question is a legal one, depending on the wording of the contract.

**THE** following communications have been handed to the General Manager:—Mr. Rigden, London; M. Neustadt and Co., London; Mr. H. Gill, York; Mr. Andrew J. Burke, Dublin; Mrs. Fox, Liverpool (with enclosure); Mr. J. Hugo, Reading; Mr. G. Gwynn, Owens; Dr. Davies, Swansea.

## MENSTRUATION AND THE CURING OF MEAT.

**SIR.**—In connection with the above subject, the following circumstance seems worth relating. It has come to my knowledge on such trustworthy authority, that I can vouch for its accuracy. A cook in a family in the West of England had occasion to cure some pork and some beef at the same time. Shortly afterwards, both of the batches of meat thus cured went bad. On expressing her surprise at this result to her fellow-servants, they asked her whether she was menstruating at the time she cured the meat; and on her admitting that she was, they informed her that that was the cause of the failure. Either from forgetfulness or incredulity, the cook not long afterwards cured some pork again whilst in the same condition as before, and again the same result followed. Such a coincidence as this hardly seems to leave room for doubt that the common belief in the connection between these conditions, which I am told is as strong in the West of England as it is in other parts, is a real one, and not a mere matter of superstition. The fact is certainly most curious, and worthy of the investigation which your correspondent "R. B. F." suggests.—Yours faithfully, R. B.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

## THE BARBER FUND.

**SIR.**—Kindly permit me to acknowledge the following contributions to this fund, in addition to those already received, making a total of £29 7s.

C. T. Brookhouse, M.D., Deptford	..	..	£2 10
William Hall, Esq., Lancaster	..	..	1 10
G. W. F. Bury, Esq., Lyonsdown	..	..	1 10

I am, sir, faithfully yours,  
Latham House, Crickhowell, April 10th, 1878.

PHILIP L. HALL.

## KOUMISS.

**SIR.**—I am afraid your correspondent "A Physician" is confounding two different things. Koumiss is a spirituous liquor, distilled from mares' milk, which is of a stimulating and intoxicating character. There is another drink prepared from cows' milk, or cows, sheep, and goats, which is rendered "butter" in our translation of the Bible. Dr. William Smith, in his Dictionary, says there can be no question that in every case (except, perhaps, Proverbs xxx and 35) the term refers to a preparation of milk, well known in Eastern countries under the name of "leben". The method now pursued in its preparation is to boil the milk over a slow fire, adding to it a small piece of old leben, or some other acid to make it coagulate. Josephus notes particularly that the refreshing draught poured out of the bottle by Jael for Sisera was "leben". At certain seasons, the poor almost live upon it in the East; whilst according to Rossel, the upper classes use it to salad or meat. How this leben was first discovered is not known, for it has been propagated from long beyond the memory of man. Some aver it was what Hagar got to drink in the desert; others, that an angel revealed the secret to Abraham. My conviction is, it was an accidental discovery. I ought to state that this fermented or acidulous beverage ought to be well shaken before pouring it out for drinking. It is kept in bottles made of animal skins; and very often the animals carry their own produce to market.

Spenser, in his book of travels in Circassia, wrote that "wines, spirituous liquors, even the boza of the Turks and Tartars, called bala-sima, is rarely used by the Circassians, their favourite beverage being 'the skhon', a species of sour milk peculiar to the East, and which I found to be a most healthful and refreshing as well as agreeable beverage during my travels in their country. Fresh milk (serend) is never used by the Circassians, being considered unwholesome, and certain to originate fevers; hence they are accustomed to boil it every morning and evening, with a little of the old skhon (leben) when the milk is cold. In three or four hours afterwards, it becomes thick and fit for use; and, when flavoured with a little rose-water and sugar, or indeed in any other form whatever, it is a most grateful and refreshing drink". It is worthy of remark, that the skhon alone gives the milk that peculiarly agreeable taste which we find in the East, and preserves it in the hottest weather in a fit state for drinking. I have condensed these extracts from my forthcoming volume on *Milk and Wine*, and fear that the difficulty of your correspondent will be to get hold of some of the genuine skhon or leben. I question if pepping wine or cream-of-tartar, or rennet, will produce anything more than curds and whey. I believe, as a sedative to the stomach in severe vomiting, the effervescent koumiss is best.—I am, sir, yours most respectfully,

Newbiggin-by-Sea, April 1878.

J. C. REID, M.D.

**SIR.**—In answer to your correspondent of March 30th, I have made koumiss for some time in the following manner. Take four quarts of milk, a pint of buttermilk two days old, and twenty-one ounces of water; stir them together in an earthenware vessel, cover with a cloth, and place in a room temperature about 56° Ceg.; after twenty-four hours, well beat and recover; after another twenty-four hours, well beat, bottle, cork tightly, tying them down; shake and lay the bottles on their sides in a cellar. It may be used in a week or ten days. It is better not to keep more than a month in hot weather, as it is then so effervescent that the bottle will completely empty itself after the cork is drawn.—I am, etc.,

April 1878.

A. S. ROE.

## IN RE BOX v. BERESFORD.

**SIR.**—We have been surprised at your decision in the above case, and also surprised that none of your correspondents have taken exception to what appears to us a decision on the *ex parte* and very imperfect statement of Mr. Box. Mr. Box's charges against Dr. Beresford have been of too general and too vague a character to admit of reply. Dr. Beresford has in each of his letters pressed for a more specific statement of the case—fearlessly, and, as we think, wisely, reserving his defence until Mr. Box should give it. This Mr. Box has never done, nor has he at any time (having regard to the circumstances of the case, of which we respectfully submit you, sir, apparently know very little), even after repeated requests, written such a letter as Dr. Beresford could reply to. Thus we have an indictment against Dr. Beresford, without any evidence in support of it beyond the *ipse dixit* of Mr. Box. Mr. Box alleges that the man had fracture of the *radius only*. Dr. Beresford does not deny the fracture of the radius, but contends that there was also fracture of the ulna. This is the case.

We examined the man individually and independently, at the request of Dr. Beresford, and were unanimously of opinion that both bones were fractured; and, from the different appearance of the several injuries, that the fracture of the ulna was not reduced at the same time as that of the radius.

Mr. Box's explanation of the tumour on the ulna as a node, etc., was too absurd to be surgical; besides, it was obviously *ad hoc*.

Dr. Beresford's long residence in Oswestry, together with the fact of his enjoying a large and highly respectable practice in that important town and its neighbourhood, are sufficient guarantee to those who know it of the estimation in which he is held; but for the benefit of your general readers, we, as his neighbours, cannot allow him to be assailed by a *comparatively* unknown man, and condemned by you, virtually unheard, without saying that, meeting him constantly, both socially and professionally, we have always found him eminently gentlemanly in either capacity, and a valuable aid in the latter.

The plaintiff being first in court has always the advantage, the *onus* being on the defendant. Let us, therefore, have from Mr. Box—1. A distinct statement of the case, without any generalisation; 2. The opinion of his two assistants (*of quality*); 3. The *exact words* of the Shrewsbury surgeons who examined the case at his (Mr. Box's) request. Then, if Dr. Beresford cannot reply, we shall feel crushed, and shall be "for ever silent".—We are, sir, your obedient servants,

G. J. MORGAN, M.R.C.S.F., Dawston, Kinnerley.  
LEONARD A. MANNING, A.M., M.B., etc., Llanyfrynach.  
R. MACMURDO GREEN, L.R.C.S. Edin., Llandrima.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### TREATMENT OF UTERINE HÆMORRHAGE.

SIR,—In your report of the Glasgow Medico-Chirurgical Society's meeting of March 1st, 1878, I see an account of an ingenious method of treating uterine hæmorrhage by Dr. D. Christie. The apparatus described is exactly like one shown me in 1863 by Mr. Sawyer, surgical instrument-maker, of London Street, Norwich, who, I remember, was greatly impressed with its value in arresting uterine hæmorrhage. It it have during the past fifteen years proved a reliable means of restraining uterine hæmorrhage. I have no doubt Mr. Sawyer has sold many, and would be able to give Dr. Christie information from the medical men who have purchased it.—Yours faithfully,  
April 2nd, 1878,  
HENRY M. JAY, M.D.

#### QUADRUPLE BIRTH.

SIR,—I think the following case, from its rarity, is worth recording. I was called to attend Mrs. G. F. D. in the middle of the ninth month of her pregnancy, and found her in labour, the liquor amni having escaped, and the head being on the perineum. The pains being insufficient, I gave ergot, and in ten minutes the child was born, followed at short intervals by three others—the first being born on March 24th, at 4 A.M., and the last at 4.20 A.M. The third was a footling, the others vertex cases. The first and fourth placenta were distinct, the second and third firmly united; the fourth, a girl, died on March 25th, at 4 A.M.; the second, a boy, died on March 26th, at 4 P.M.; the first, a girl, died on March 27th, at 6 A.M.; and the third, a boy. The mother is progressing favourably. She has had one child previously, three years ago.—I am, etc.,  
CLEMENT HADLEY, M.R.C.S.

#### RHAMNUS FRANGULA.

SIR,—A *profus* of "Rhamnus Frangula," I find the following in the *Pharmacopœia Londinensis*, or the *New London Dispensatory*; as also the *Præcis of Chymistry*, by William Salmon, Professor of Physics; 1682. Chap. 2, of Barks. 11. "Frangula alba nigra, of the black alder tree. The inner bark purgeth both flegm and choler by stool and vomit. An infusion of it, taken for some mornings together, helps the rickets, cachexia, dropsy, jaundice, itch, or mange, causing a good appetite and a healthful constitution." Thirty-five years ago, an old and valued medical friend, talking of turpentine as then much used by Nægele in puerperal fever, warned me against its use in pregnancy; "for," said he, "I gave it once to a young woman, not knowing that she was pregnant, to expel worms, and it scotched the worms, and a three months' foetus too!"—I am, etc.,  
124, Fulham Road, March 1878.  
V. POULAIN, M.D.

#### PROPOSED REGISTRATION OF FOREIGNERS WITHOUT DIPLOMAS.

SIR,—I should like to call the special attention of the profession through your columns to one of the clauses in the Government Medical Bill, by which power is sought to be given to the Medical Council to place upon the *Register* any foreign practitioner of ten years' standing whom they may consider "eminent," without requiring the production of any diploma or qualification. I refer to Clause 8 of the Bill, which I will not occupy your valuable space by quoting *in extenso*, as your readers will find it on page 426 of the *JOURNAL* for March 23rd. Now, sir, unless this clause is intended to admit to the *Register* some unqualified person or persons, it is wholly unnecessary. By Clause 6, any foreign practitioner of ten years' standing, whether "eminent" or not, who can show that he holds a recognisable foreign diploma or diplomas, can claim registration without examination. What, then, is the necessity for Clause 8? It would almost seem as if it had been specially introduced to meet the case of some unqualified person whom the Council consider "eminent." If such be the fact, surely the profession should demand its expulsion from the Bill; and if such be not the case, it should equally be expunged as being unnecessary. The whole Bill requires the most careful reading and consideration by the profession, and I trust the British Medical Association will give it earnest attention.—Apologising for occupying your space, I remain, yours, etc.,  
April 2nd, 1878.  
W. DOUGLAS HEMMING.

#### EFFECTUAL TREATMENT OF THE HYSTERICAL PARONYMUS.

SIR,—Some time ago, a lady-patient of mine drove up from her husband's place of business, requesting me to visit her servant, who, she had just heard, was either dead or dying. I did not know until I arrived that "Observer" was in the house, and it is simply a fabrication of his that I "rushed in, protesting," etc. "Observer" had by this time got the girl, her clothes, and the furniture thoroughly well drenched, *secundum artem*, as he calls it; and, for all the effect produced, he also might as well have stood mutely gazing on the prostrate form. He was in doubt whether it was a hysterical or an apoplectic seizure. I suggested, and with his sanction adopted, the method he mentions. He was "thus accessory to the 'criminal assault'." I think this by no means original plan is, under certain and proper circumstances, preferable, and less of an assault, than half-drowning a patient without any satisfactory result.—I am, etc.,  
Regent Road, Salford, April 1878.  
J. CRAN, M.D.

#### ATTENDANCE OF FAMILIES OF MEDICAL MEN.

SIR,—"Another Member" states that his fee has been accepted by consulting physicians and surgeons, and I can only express my surprise if, as he says, he took care to let it be known that he was a practitioner. But I have to complain that on more than one occasion medical men who have done me the honour to consult me for themselves or their families have not at once announced the fact of their being professional brethren; but have, from what motive I cannot tell, guarded the secret until the end of the visit, with its anticipated *honorarium*. In one case particularly I found that another "consultant" had taken a fee—I believe in pure ignorance, for I was in such doubt as to the character of my visitor that I had to put the question point-blank, "Are you a medical man?" In common with my London brethren, I am happy to assist my professional brothers and their immediate connections as far as lies in my power; but I would venture to put it to them, in all kindness, *not* to telegraph as if the case were one of extreme urgency, when delay is of little importance, and *not* to pass by professional assistance from neighbouring cities of equal value with that of London, simply because they fancy a name.

Lastly, may I say that I think although no fee is either demanded or expected from a professional brother, yet a consultant ought not to be allowed to be out of pocket for railway fare, etc.—Yours obediently,  
April 1878.  
A LONDON SURGEON.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the *BRITISH MEDICAL JOURNAL*, should arrive at the Office not later than 10 A.M. on Thursday.

SIR,—Upon public grounds I ask you to insert the accompanying letter in next Saturday's issue of the *BRITISH MEDICAL JOURNAL*, and am, sir, your obedient servant,  
Llanbister, March 30th, 1878.  
T. J. EAMES BROWN.

(Copy.)

"Dear Sir,—Unfettered by political party ties, but, nevertheless, a true Conservative, and a loyal member of the profession to which I have the honour to belong, I appeal to you, as the representative of this county in the Commons House of Parliament, on behalf of my professional brethren engaged in her Majesty's military, naval, and auxiliary forces, to bring your influence and interest to bear upon the Government, with the view, if possible, of bringing to perfection, for public use, the services connected therewith, both upon professional or private, and national or public, grounds. Allow me to suggest what a pretty pickle this country would be in should the Premier most unjustly drag us into an European war with the present unsatisfactory state of affairs, caused solely by the Government withholding justice from the medical departments of the above important services. I also ask you for some measure of justice to be meted out by the Local Government Board towards those members of my profession who happen to be employed in that service, but who, from *obligation of vision*, from which the members of that board are unfortunately suffering, fail to receive that justice which they merit.—I remain, dear sir, your obedient servant, T. J. EAMES BROWN.—To the Honourable Arthur Walsh, M.P."

AN OLD ASSOCIATE.—The question is rather legal than medical.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Chicago Times; The Manchester Guardian; The Berkshire Chronicle; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Daily Courier; The Middlesex County Times; The Liverpool Evening Advertiser; The Daily Courier; The Kelso Chronicle; The Fifeshire Herald; The Merthyr Express; The Carnarvon and Denbigh Herald; The Surrey Advertiser; The Stroud News; etc.

\* \* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

COMMUNICATIONS, LETTERS, etc., have been received from:—

# THE GOULSTONIAN LECTURES ON THE LOCALISATION OF CEREBRAL DISEASE.

*Delivered at the Royal College of Physicians of London.*

By DAVID FERRIER, M.D., F.R.S., F.R.C.P.,

Professor of Forensic Medicine in King's College; Assistant-Physician to King's College Hospital; etc.

## LECTURE III.—March 22nd.

II. *Irritative Lesions of the Motor Area.*—Hitherto I have directed your attention more particularly to destructive lesions of the motor area indicated by paralysis of voluntary motion, general or partial, theoretically separating them from irritative lesions indicated by unilateral convulsions or monospasms. Practically, however, they cannot be separated from each other by a hard and fast line; for many cases of limited destructive lesions are associated with unilateral convulsions or monospasms, and I have already referred to instances of this association. There are numerous cases, however, in which the predominant, and sometimes the only, feature has been a convulsive affection limited to a limb or combined in the way in which monoplegiae are combined, or which, commencing in a constant and definite way, becomes generalised into an unilateral convulsion with or without loss of consciousness, or occasionally passes into bilateral convulsions. It is the great merit of Hughlings Jackson to have first clearly indicated the pathology of these affections.

I have already alluded to some of the observations and generalisations which had been made by Bravais, Bright, Wilks, etc.; and I ought to mention here the very close approximation to regional localisation of the lesions most commonly causing convulsive affections of the opposite side at which Mr. Callender\* arrived. Callender concluded that convulsions occurred more particularly with superficial lesions of the cortex in the neighbourhood of the middle meningeal artery: an approximation amply borne out by subsequent clinical and experimental research.

From the mere occurrence of an unilateral convulsion with loss of consciousness, or of an epileptic attack in which the convulsions are exhibited mainly on one side, we can form no opinion as to the nature or seat of the lesion. We may suppose, and with reason, that the opposite cerebral hemisphere is more particularly at fault; but there need be no discoverable lesion; and, should a lesion exist, it need not be in any definite position. This is in accordance both with clinical facts and also with those of experiment, for I have found that long continued irritation applied to any part of the hemisphere other than the motor area may result in an attack of unilateral convulsions. If, however, the convulsion be of the character of a monospasm, or if, tending to become generalised, it begin invariably in the same way and do not cause loss of consciousness, and if it be followed by paresis or paralysis more or less permanent, we may diagnose an irritative lesion of the motor area of the opposite hemisphere.

The seat of the lesion may be approximately determined by the rules as to the localisation of destructive lesions, but only approximately, as the diagnosis of the seat of an irritative lesion is naturally more uncertain than that of a destructive lesion, owing to the difficulty of determining the extent of the zone or the special point in this zone in which vital irritation concentrates itself. Yet many cases are on record in which the phenomena of irritation have been such as to allow exact regional diagnosis in accordance with the principles of localisation of distinct centres.

The morbid anatomy of irritative lesions is various. They are all such as tend to induce irritability and hyperæmia of the cortical grey matter or subjacent medullary tracts: a condition which I have invariably observed in my own experiments. Magnan† has found the same condition of hyperæmia of the cortex in the epileptic convulsions induced by the introduction of absinthe into the system; and MM. Pitres and Franck‡ have shown that, in the partial or unilateral epileptiform attacks to which dogs are liable after injury to the cortex, the grey

matter surrounding the cicatrix is so hyperæmic, tumefied, and irritable, that even mechanical stimulation, which normally has no effect, is sufficient to cause motor discharge.

The irritative lesion may, therefore, be an acute inflammation, or a condition of irritability set up by some chronic morbid product. Most frequently the lesion is some form of meningo-encephalitis; and of these syphilitic disease is by far the most common, so that now syphilitic epilepsy is sometimes spoken of as synonymous with "Jacksonian epilepsy". Tubercular affections, tumours or cysts situated superficially, cicatrices of old wounds, spicula of bone, etc., are all capable of producing irritation.

Hughlings Jackson is of opinion that the lesion causes the centres to become charged to a state of high tension, so that, under certain vital conditions, they discharge themselves in a sudden and explosive manner, and become exhausted for the time being; hence the temporary epileptic hemi- or monoplegia. This would account for the occurrence of intermittent effects with a constant lesion; for, according to the law of discharge formulated by G. H. Lewes,\* stimulations which fall short of actual discharge of a nerve-centre increase the tension; hence, after a certain accumulation of stimuli, sudden discharge is readily induced.

Frequently the disease, which begins as an irritative lesion, tends to invade and destroy the region on which it grows, and leads to permanent paralysis with secondary degeneration; irritative phenomena being liable to occur so long as the vitality of the grey matter and subjacent medullary fibres has not been absolutely annihilated.

"Jacksonian epilepsy", in the early stages at least, has frequently the character of a monospasm, which may be brachial, facial, or crural, or these combined, as in the manner of monoplegiae. When the monospasm tends to become generalised into unilateral convulsion, the spasms seem to march usually in a certain definite order. In facial monospasm, the arm next becomes affected, and then the leg. If it commence in the hand, it goes up the arm, then to the face, and next attacks the leg. If it begin in the leg, it next invades the arm, and then the face. This order is very rarely inverted. Usually, when the convulsions have become unilateral, consciousness is lost, if not before. When the convulsion becomes bilateral, as is sometimes the case, Hughlings Jackson finds that the spasms march in the reverse order; e.g., if it have passed to the leg from the face, it ascends the opposite leg, and so to the arm and face. I have not confirmed this in experiments on animals, for I have frequently seen the same order followed on the other side as on that on which the spasms began. It would be in accordance with the bilateral association of motor nuclei (which Dr. Broadbent has applied so successfully to the explanation of the comparative escape of bilaterally associated movements in cerebral disease), that bilaterally associated movements should have most tendency to be discharged together. This fact has been well brought out by MM. Franck and Pitres, for they have shown that bilateral convulsions may still occur from excessive irritation of one hemisphere even when the motor centres of the other have been extirpated.

And many clinical cases might be cited which do not harmonise with the views of Hughlings Jackson as to the march of bilateral spasms.† It is not, however, my intention to discuss at length the pathology and symptomatology of irritative lesions: subjects which are well known to the profession in this country through the writings of Hughlings Jackson, and abroad more particularly through the writings of M. Charcot. I will content myself with calling attention to one or two of the more accurately recorded cases of circumscribed lesions with irritative symptoms, in order to show how closely the situation of irritative lesions (notwithstanding all the elements of uncertainty pertaining to them, as compared with destructive lesions) may be determined from the symptoms manifested; and, as I have already intimated, I allude only to those in which irritation or spasm was the predominant or only symptom, and only to those verified by *post mortem* examination, though I might justifiably cite others of the same kind, depending particularly on syphilis, which recover.

1. *Crural Monospasm or Protospasm.*—Of spasms limited to the leg, or invariably commencing in the leg, there are not many cases on record free from complication with paralysis, or in which the lesion remained circumscribed till death. I have already quoted two cases from Bourneville, in which crural monospasm complicated with paralysis was the chief symptom. A case is recorded by Broca‡ of crural monospasm cured by injury to the left side of the skull which was

caused by trephining; but the exact position of the lesion I do not find recorded.

MM. Charcot and Pitres\* quote a case from Griesinger of spasm of the leg frequently recurring, and also invading the arm, followed in the intervals by paralysis of the leg and arm. The lesion, however, was not strictly limited in this case. A hydatid cyst,  $4\frac{1}{2}$  centimetres  $\times$   $4\frac{3}{4}$  centimetres, was found on the surface of the opposite hemisphere, in such a position that its anterior border corresponded with a line drawn perpendicularly upwards from the external auditory meatus, *i.e.*, about the upper extremity of the fissure of Rolando. There were also several smaller cysts on the frontal and parietal surface of the hemisphere. If the spasm can be ascribed exclusively to the large cyst, then its position agrees with the motor centres of the leg. (Fig. 15, [1] [2].)

Hughlings Jackson† has described a case in which fits began almost invariably in the right leg, and were frequently limited to it. The leg began to become weak, and more so after each fit, the paresis deepening ultimately into a permanent paralysis. In the last stages, signs of general affection of the left hemisphere—aphasia, etc.—manifested themselves. A tumour was found at the upper posterior part of the left frontal lobe, about two inches in diameter, bounded posteriorly by the fissure of Rolando, and extending forward into the posterior part of the first and second frontal convolutions.

Another case is given by Hughlings Jackson‡ of convulsions beginning in the left great toe, often confined exclusively to the left leg, and followed ultimately by paresis of the left foot. This patient also had paralysis of the right third nerve. After death, a syphilitic lesion was found "at the upper part of the posterior ascending or ascending parietal convolution, extending over part of the upper end of the ascending frontal and over several of the adjacent convolutions of the parietal lobule" of the right hemisphere. On the right third nerve, a tumour of the size of a pea was found. This case is in exact correspondence with the situation which I have assigned to the motor centres of the foot and leg. (Fig. 15, [1] [2].)

2. *Brachial Monospasm or Protospasm.*—Of spasms limited to, or beginning in, the arm or hand, depending on localised cortical lesion, there are several cases on record. As a rule, the fits begin in the fingers, and more especially in the thumb and index finger—in the most volitional movements of the upper extremity, according to Hughlings Jackson; but this is not necessarily or invariably so. In the upper extremity, it must be remembered, there are several combinations of movements which have each a representative in the cortical motor area. These centres being all situated within a moderate compass, and all liable to be discharged by one irritative lesion, it is nevertheless possible that each may be the primary origin of the discharge, and so the mode in which the monospasm commences may vary accordingly. Hence the necessity of making minute investigation of the march of the spasm in any particular case.

Hughlings Jackson has recorded several cases of brachial monospasm. I will only mention those in which the lesion of the cortex was single and limited. A man had frequent convulsions limited to the right arm, which subsequently became partially paralysed. A nodule was found situated at the hinder extremity of the first frontal convolution of the left hemisphere. In this case, there was also a tumour in each lobe of the cerebellum, but there were no cerebellar symptoms. The march of the spasm was not recorded.§

In a second case of convulsions, nearly always limited to the right arm, and followed by temporary paralysis of that arm after each fit, the lesion, which was diagnosed by Hughlings Jackson during life, was a nodule, situated at the "posterior extremity of the first frontal convolution where it joins the ascending frontal". In this case, it was noted that the spasms always began in the shoulder and went down the arm, contrary to the usual order. This is an important case, as showing that the spasm began in muscles which, as the experiments on monkeys indicate, relate to the movement of the arm as a whole, and not to those of the fingers or wrist. (Fig. 15, [3] [4] [5].)

In a third case,¶ convulsions invariably began in the left thumb. After death, a tumour of the size of a hazel-nut was found under the grey matter at the posterior extremity of the third frontal convolution of the right hemisphere. Some granulations existed in the bed from which it was enucleated, or in the grey matter near it.

In a fourth case, the spasms began in the right hand, and occasionally in the right cheek. Before death, left hemiplegia came on,

which, however, soon passed off. Disease was found in both cerebral hemispheres, probably syphilitic. In the left hemisphere, *i.e.*, the side opposite the spasms, adhesion was found between the dura mater and the brain in a region including "the lower part of the ascending frontal and ascending parietal convolutions, to a trifling extent to the hinder part of the third frontal, and several of the convolutions of the upper wall of the fissure of Sylvius behind the ascending parietal". In the right hemisphere—the side opposite the paralysis—"on the surface, behind the fissure of Rolando, was a mass about the size of a chestnut. The dura mater was firmly adherent to it. There was very little softening about it."<sup>\*\*</sup>

In a fifth,† temporary right hemiplegia came on after an unilateral convulsion in which the patient did not lose consciousness. Convulsions occurred from time to time, beginning in the little finger of the right hand, occasionally in the right cheek, and followed always by slow and hesitating speech. After death, a syphilitic tumour of considerable size—as large as three small walnuts—was found growing into the cortex about the junction of the frontal and parietal lobes, surrounded by an area of softening in the posterior part of the frontals, ascending frontal and ascending parietal, and partly of the island of Reil. The sphenoidal lobe was also softened. This case, though of interest, is rather a complex one, and should, perhaps, scarcely be quoted as a limited lesion.

Dr. Dreschfeld‡ has recorded a very interesting case of brachial monospasm depending on syphilitic disease, the nature and position of which he accurately diagnosed during life. The patient suffered from repeated attacks of convulsion limited to the left arm, of which the phenomena were "sudden clenching of the fist, flexing of the wrist, and pronation of the forearm of the left side, the left angle of the mouth being at the same time strongly drawn downwards. This sudden tonic spasm lasted for several seconds, and was then followed by a few clonic spasms of the same extremity and a slight tremor of the arm; the patient at the same time was very agitated and looked very pale, but remained perfectly conscious. He stated that these paroxysms had always had the same character, varying only in degree". Death occurred from phthisis two years after the first onset of the disease. On *post mortem* examination, the dura mater was found adherent to the brain on the right side, over a space including the greater part of the ascending parietal convolution and the supramarginal lobule (fig. 21, *a* and *b*).

To these cases, in which irritative symptoms chiefly predominated, I may add one or two others, which may be considered as belonging

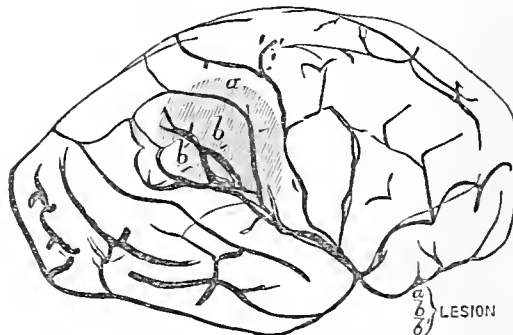

Fig. 21.

equally to irritative and destructive lesions. The cases are reported in full by MM. Charcot and Pitres §. A case is recorded by Lepine, of left hemiplegia, followed by convulsions, limited chiefly to the left arm. A small hæmorrhage of the size of a nut was found at the "posterior extremity of the first frontal convolution of the right hemisphere". In another, by the same observer, of left hemiplegia, convulsions occurred, either limited to the left arm, or invariably commencing there. A yellow patch was found at the base of the first and second convolutions of the right hemisphere. A third case is given by Mahot,¶ of monoplegia and monospasm of the right arm. A glioma of the size of a pigeon's egg was found on the middle third of the ascending frontal convolution of the left hemisphere. In a fourth, recorded by Henrot, convulsions began in the fingers of the left hand, and were repeated at intervals, followed by left hemiparesis. A mass of tubercle

was found embedded in the grey matter of the ascending frontal convolution of the right hemisphere, about the middle third. In this case, however, there was also a small tubercular mass on the right side of the pons.

It will be seen from these cases that the situation of the lesion causing brachial monospasm is not an accurately circumscribed one; and yet there is a greater agreement among them, when viewed in the light of experimental localisation of the brachial and manual centres, than may at first appear. As has already been said, there are several centres, each for a distinct movement. In four of these cases, in which the spasms were said simply to be in the arm, and in one of them in which it was noted that the spasms began in the proximal movements of the arm, the lesion was situated at the hinder extremity of the first frontal convolution, a position which, as will be seen by reference to the figures (figs. 15, 16 [5]), corresponds with the localisation of the centres of such movements in this region.

In some cases, there was no exact description of the march of the spasm; but in those in which it was more especially noted that the spasms began in the fingers or hand, the lesion was either in, or in close proximity to, the ascending parietal convolution, in which, in the monkey, these movements are especially centralised. Of these, Dreschfeld's case is the most striking, both as regards the precise character of the movements and the limited extent of the lesion, so precise as to have allowed of exact diagnosis, which was verified to the letter *post mortem*.

**3. Facial Monospasm or Protospasm.**—Though partial epileptiform convulsions beginning in the face are not uncommon as symptoms, and not unfrequently alternate with convulsions beginning in the hand, yet there are very few cases on record of facial monospasm, uncomplicated with brachial monospasm or other convulsive or paralytic symptoms, in which the position of the lesion has been verified by *post mortem* examination.

The cases of Hitzig and Wernher, already quoted, in which oral and facial monoplegia and facial monospasm alternated, are about the best examples of this on record. The lesion—the principal, at least—in these cases was the same in position, viz., the lower extremity of the ascending frontal.

A very interesting case, illustrating another fact of experimental localisation, has been recorded by Dr. Bramwell.\* A woman, who had received a cranial injury some years previously, began to have right-sided convulsions, and numbness in the thumb and forefinger, followed by paralysis of the right arm and leg. She remained subject to frequently repeated convulsions, which always began in the right platysma, and frequently were almost entirely confined to this muscle. On *post mortem* examination, a spiculum of bone was found projecting from the inner table of the skull, and causing a very limited lesion of the inferior margin of the ascending parietal convolution. A reference to the figure of the brain of the monkey (fig. 15, [11]) will show that at the lower extremity of this convolution, and just posterior to the oral and lingual centres, there is an area marked off, irritation of which specially causes action of this muscle. Bramwell's case receives its explanation from this fact, and in Dreschfeld's case, in which spasm of the platysma was also a special feature, the lesion affected this point. Clinical and physiological experiment are here again in harmony.

#### B.—LESIONS OF THE SENSORY REGIONS.

I will now direct your attention to the subject of lesions of the sensory regions of the cerebral hemispheres. That the cerebral hemispheres are the seat of sensation or—in order to avoid disputes as to the meaning of sensation—of sensory perception, is abundantly evident both from the results of experimental physiology and from the facts of clinical medicine. And that the regions of the brain we have already considered, viz., the fronto-parietal regions, may be disorganised without causing loss of sensory perception, I consider to be demonstrated both by the facts of experiments on monkeys, and by the clinical evidence which I have laid before you. Some statements which have been made to the contrary, based on experiments on dogs and rabbits, are, as I hope to be able to show you further on, susceptible of a totally different interpretation, and one in harmony with what I have said respecting monkeys and men.

It is clear, therefore, that if the centres of sensory perception are localised in the hemispheres—and this, I think, no one will dispute—they are to be sought for in those regions yet remaining to be considered, viz., the occipital and parieto-temporal lobes. That this is so, we should be led to believe from anatomical as well as from other considerations. For, though I do not place much reliance on mere ana-

tomical investigation as a means of determining the exact course and destination and various connections of the cerebro-spinal tracts, yet, so far as main features are concerned, it furnishes us with substantial bases for other lines of research. It has been established, I think, beyond doubt, that the posterior strands of the crus, and their connections with the brain and the cord, are more especially the paths of centripetal or sensory impressions. The researches of Meynert and others would seem to show that these tracts are connected with those parts of the cortex which we are now considering. Beyond these general indications, however, I have considerable doubts as to the results of anatomical localisation. But in addition to general anatomical indications, we have experimental and pathological evidence as to the exact position of the paths which convey sensory impression to the cortex.

The experimental evidence has been furnished by the researches of Veyssière,\* which have been repeated and verified by Carville and Duret, Raymond, and others. These experiments show that when section is made of the posterior part of the internal capsule, that part of the "projection system" which lies between the optic thalamus and lenticular nucleus of the corpus striatum (fig. 22 [x]), there ensues a

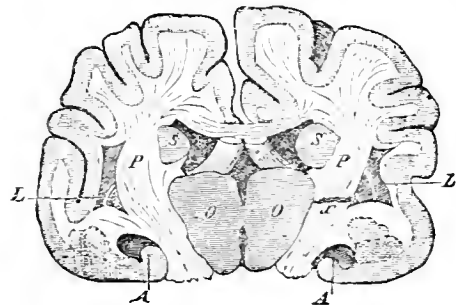

Fig. 22.

condition of hemianæsthesia of the opposite side of the body, frequently associated, temporarily however, with some degree of motor paralysis; whereas when the anterior part (two thirds) of the internal capsule (fig. 23)—that part lying between the caudate and lenticular

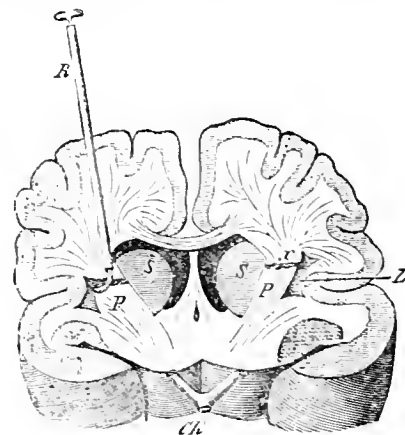

Fig. 23.

nuclei of the corpus striatum—is divided, motor paralysis, unaccompanied by sensory paralysis, or if so, functional and fleeting, is the constant result.

The facts of human pathology are no less precise. Motor hemiplegia is invariably the result of destructive lesion of the anterior two-thirds of the internal capsule, which may be accompanied temporarily by hemianæsthesia, if the lesion be such as to cause pressure, or functional disturbance of the posterior third. And we have now a tolerably large body of evidence to show that destructive lesions limited to the posterior third of the internal capsule cause cerebral hemianæsthesia.

The first observations relative to this localisation were made by Türck†

\* BRITISH MEDICAL JOURNAL, August 28th, 1875.

\* Sur l'Hémianesthésie de Cause Cérébrale, 1874.

† Sitzber. der kais. Acad. der Wissensch., Band XXXV, 1859.

in 1859, and since then, Charcot, Magnan, Bourneville, Rendu, Raymond, Pierret, Decaudin, Pitres, Boyer, etc., by their observations and researches, have established the pathology and symptomatology of this affection in a manner which leaves little to be desired.

Since the publication of Türck's four cases, in 1859, of the association of hemianæsthesia with lesion of the posterior part of the internal capsule, there have been recorded at least twenty others, all establishing the same fact.\*

The symptoms of cerebral hemianæsthesia, which correspond with those of that strange and, as regards its therapeutics, mysterious affection termed hysterical hemianæsthesia, are such as to clearly differentiate it from anæsthesia of spinal or mesencephalic origin. The special diagnostic feature is, that all the forms of sensibility, general or special, are impaired or abolished; the organs of sense whose nerves take origin above the medulla oblongata being equally affected with those which arise here: whereas, in mesencephalic anæsthesia, in addition to the usual association of alternate paralysis, sight and smell remain unaffected.†

In cerebral hemianæsthesia, tactile sensation is affected unilaterally up to the middle line of the face and trunk; there being more or less complete insensibility to touch, pain, temperature, and also abolition of muscular sensibility, with complete retention of electro-motor contractility. The conjunctival, nasal, buccal, and cutaneo-mucous membranes are also anæsthetic. The viscera, however, remain sensitive, and deep pressure, as on the ovary, etc., is felt as before. In hysterical hemianæsthesia, there is usually hyperæsthesia in the ovarian region, and frequently also the condition termed by Charcot hysterio-epilepsy. Taste, smell, and hearing, are deficient or almost entirely abolished in a similar manner on the one side. As regards vision, the symptoms are especially noteworthy. The eye on the anæsthetic side is rarely rendered completely blind. There is rather a condition of amblyopia or diminution of the acuteness of sight, and a very remarkable contraction of the field of vision, more especially as regards the perception of colour. Landolt has found that the field of colour-perception becomes contracted in a manner corresponding to the relative extent of the colour-field in the normal state. Normally the blue field is the largest, next the yellow, orange, red, green, and last in order the violet, which is perceived only by the most central parts of the retina. In cerebral hemianæsthesia the sensibility for violet first disappears, then for the green, and later for the orange. Sensibility for yellow and blue may still persist; but in the higher degrees of anæsthesia, all colours merge into an uniform sepia tint. Landolt‡ has lately pointed out another important fact, viz., that the affection of vision is not altogether unilateral, but that the eye on the side of lesion participates, though to a less extent, in the anæsthesia.

It is further noteworthy that in this form of amblyopia, ophthalmoscopic examination reveals no organic lesion or degeneration of the optic nerve or retina, in the first instance at least; any atrophic changes which may show themselves subsequently being the consequence and not the cause of the blindness.

It is clear from these facts that the older theories respecting the decussation and distribution of the fibres of the optic tracts, and the representation in each hemisphere, only of the corresponding parts of both retinæ, are untenable. If this were the case, we should have, as the result of a central lesion, a hemiopia of both eyes; whereas we have not a hemiopia, but an amblyopia, which, though to some extent bilateral, is most marked on the side opposite the lesion.

Yet we know that hemiopia is not an uncommon symptom in connection with intracranial disease; but from the facts mentioned, we may conclude that in such cases the lesion must be situated below the cerebral cortex.

The scheme of the optic tracts and their relations, given by Charcot, enables us to give a satisfactory explanation of these facts. (Fig. 24.) Each optic tract contains two sets of fibres; the outer, passing to the eye on the same side; the inner, decussating with their fellows of the opposite side in the chiasma and passing to the corresponding part of the opposite eye. The fibres which do not decussate in the chiasma undergo decussation in the corpora quadrigemina, and pass on with the fibres which have done so to the opposite hemisphere, so that each hemisphere is brought into relation with the whole of the opposite eye. This scheme does not represent the bilateral relation of each hemisphere to both eyes, which is indicated by Landolt's researches; but we can account for this by the bilateral association in the lower ganglia. It is easy to see that a lesion of the one optic tract (κ fig. 24)

will cause bilateral hemiopia; and that a lesion in the region of the corpora geniculata (CG), or posterior part of the optic thalamus, will have a similar effect, as in a case reported by Hughlings Jackson.\* We

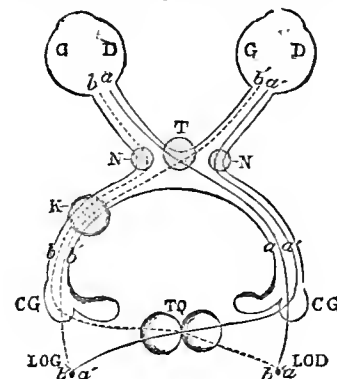

Fig. 24.

may also have cross amblyopia and bilateral hemiopia, as in a case reported by Gowers,† but as there was no necropsy, the position of the lesion is only a matter of speculation. I hope to be able to show you that these clinical observations are in harmony with the results of my experiments on monkeys.

It is evident that the lesion which causes hemianæsthesia, being in the medullary fasciculi, produces this effect, not by destroying the centres of sensory perception, but by causing solution of continuity of the paths of centripetal impressions; and the question is, whether the sensory fibres, like the motor fibres of the internal capsule, are distributed to localisable areas in the cortex. On this point, experimental physiology is, I think, in some respects at least definite enough; though it must be admitted that the same cannot as yet be said of clinical medicine and pathology. To these let us now turn.

*Lesions of the Occipital Lobes.*—I will first direct your attention to the occipital lobes, and compare the results of experimental investigation with the facts of disease of these regions. In reference to experimental investigation, we must rely mainly, if not exclusively, on experiments on monkeys; as in other animals these lobes are not specially differentiated and developed. I have found, as the result of numerous experiments, that electrical irritation may be applied to the occipital lobes without producing any objectively discoverable reaction. Neither does destruction or complete removal of these lobes singly, or on both sides, cause any appreciable sensory or motor disturbance. Animals so mutilated continue to see, hear, touch, taste, and smell, and retain all their powers of voluntary motion. The results of destruction, like those of irritation, are, therefore, mainly negative, and do not succeed in throwing very clear light on the functions of these regions. In one or two instances, I should mention that there seemed to be some affection of vision; but in these cases, I found that the lesion had extended beyond the occipital lobes, into the angular gyri; while in those in which the lesion did not extend beyond the occipital lobes, no such symptoms occurred. As a rule, the animals rapidly succumbed, with one exception; and I also observed that, contrary to the usual effects of destructive lesion of other parts of the hemispheres, the animals refused to eat: an occurrence which, from my numerous and close observations of the effects of destruction of every other part of the brain, I regard as in some way causally related to this lesion.

I admit that the inference as to causal relationship is considerably weakened by the fact that, in one of the animals in which I had removed both occipital lobes, the appetite for food returned after five days' abstinence. I have, however, attempted, whether successfully or not, to explain this, and propounded the hypothesis that the occipital lobes are specially related to the visceral sensibilities, and are the anatomical substrata of the correlated feelings which form a large portion of our personality and subjectivity. Whether the hypothesis is well founded or not, I leave to further investigation; but one thing is, to my mind, clearly established by these experiments, viz., that lesions of the occipital lobes, whether unilateral or bilateral, cannot be regarded as the direct cause either of motor or special sensory affections; and, therefore, I would at once discard the anatomical views of Meynert, Hugue-

\* For references, etc., see Grasset, *Localisations dans les Maladies Cérébrales*. Montpeller, 1878.

nin, and others, which would place the central terminations of the optic tracts in the occipital lobes. They are not, I think, in harmony either with physiological experiment, or, as far as I can discover, with the facts of human pathology.

Though many speculations exist, to some of which I shall refer, as to the symptoms dependent on lesions of the occipital lobes, it does not as yet appear, as the following cases will show, that there are any symptoms, attaching to disease of these lobes, so definite and constant as to establish any direct causal relationship between them, or indicate the functions which these regions subserve. Lesions of the occipital lobes are, as a rule, *latent*.

M. Vauttier\* records a case of yellow softening of the right occipital lobe, and, to a larger extent, of the internal aspect of the left (quadri-lateral lobule). No affection of motion or sensation existed; and, with the exception of considerable hebetude, there were no other symptoms of cerebral affection.

Pitres† relates a case, in which, in consequence of a fall on the head, an abscess, the size of a billiard-ball, formed in the postero-inferior aspect of the brain. There was no paralysis of motion or sensation, and mental obtuseness was the only indication of cerebral lesion.

Sir W. Gull‡ has recorded a case of abscess of the left posterior lobe, also without any objective symptoms.

A similar case, in which the abscess was situated in the right occipital lobe, is recorded by Rodocalat.§

Other cases, reported by Blyenye, Hébreau, Martinet, Merriman, Ogle, Parrot, Ballinger, etc., are cited by M. Pitres in his before mentioned work,|| to which I would refer the reader.

It may be said, in reference to these cases, that the lesions being unilateral, and of slow growth, the absence of symptoms may be explained by functional compensation by the same or the opposite hemisphere. There are, however, some cases on record of traumatic lesions of the occipital lobes, also negative as regards objective symptoms.

Marcé¶ records a case of contusion, with effusion into the meninges, and softening of the cortex in the right occipital lobe, without any symptom as regards sensation or motion.

In addition to Vauttier's case already mentioned, a very important case of bilateral lesion of the occipital lobes has been put on record by Sestie.\*\* In Sestie's case, there was an abscess in each occipital lobe, without any objective symptom; although the patient's memory was somewhat defective, there was nothing very remarkable in his mental condition.

Leger†† relates a case of tumour invading both occipital lobes, in which, beyond general mental obtuseness and headache, there were no objective symptoms. Sight was not impaired in this case, notwithstanding the existence of a cerebral tumour in this region. Except, therefore, as regards the fact of latency of lesions of the occipital lobes, these cases do not give us much positive material for generalisation.

Joffroy‡‡ attempts to establish a relation between lesions of the occipital lobes and the occurrence of acute sloughing of the sacrum; and thinks that the occipital lobes may be trophic centres. He quotes three cases in support of this hypothesis. One, a case of general paralysis, in which, though the cerebral lesions were not confined to the occipital lobes, yet the sacral sloughing was greater on the side opposite the lobe most affected. In the other two, there was only slight unilateral lesion: in the one case, a small focus of hemorrhage; in the other, of softening, with sloughing on the opposite side of the sacrum.

But, in reference to this hypothesis, it needs only to be remarked that sacral sloughing occurs in connection with hemiplegia where no affection of the occipital lobes has been detected; and lesions of the occipital lobes are not even commonly associated with such results. Cases have occurred, and been carefully examined, in reference to this point since the publication of M. Joffroy's views, without confirming them. One such case is reported by Sazic,§§ and another by Dreyfus-Brisac.||| These may be taken in conjunction with the other cases mentioned; for it is not likely that such a serious objective affection would have been overlooked had it actually existed.

In connection with softening of the occipital lobes, M. Charcot has occasionally noted, in addition to headache, etc., cutaneous formication and similar subjective sensations, but no true anæsthesia.

Hughlings Jackson and Bastian are of opinion that disease of the posterior lobes is more frequently associated with mental derangement than disease of the anterior lobes or other parts of the brain. Hughlings Jackson goes somewhat further, and thinks that such derangements, particularly "defective perception", are more commonly seen when the right side is affected, and that irritative lesions here give rise to coloured vision and other subjective ocular spectra. These are not put forward, however, as other than hypotheses, and I agree with Dr. Bastian when he says: "More extended observations, however, seem needed before we can safely arrive at a positive conclusion on this difficult subject."\*

Even on my own hypothesis as to the relation between the occipital lobes and the organic sensations, I should regard it as highly probable that lesions of the occipital lobes should cause profound mental disturbances. For, if our feelings are our chief motors, it might readily be allowed that lesions of the anatomical substrata of such an important element of our feelings and emotions should lead to mental derangement.

But, not to indulge further in speculation, I think we have to admit that up to the present the facts do not yet enable us to generalise with certainty as to the positive effects of lesions of the occipital lobes. It is clear, however, from the negative effects of extirpation or disease that we cannot place in the occipital lobes the central terminations of the fibres of the internal capsule which convey impressions of special sense to the cortex.

[To be continued.]

## CLAUDE BERNARD:

### A LECTURE

*Delivered to the Senior Class of Physiology at the Physiological Laboratory, New Museums, Cambridge.*†

By MICHAEL FOSTER, M.D., F.R.S.,  
Trinity Prælector in Physiology.

IN order, however, that you may understand the beginning of this matter, I must take you back a little.

Possibly it has never occurred to you that there was a time when the plain unstriated muscular fibres of the arteries were things unknown, or at least not believed in; and yet it is less than forty years ago (1840) that their presence was first demonstrated by Henle. Just imagine what lame and mutilated answers you would send up, in your examinations, if you were forbidden to employ any reasoning which involved the existence of muscular contractility in the arteries. You would be brought to a standstill, not in questions only belonging directly to the circulation, but in almost all kinds of physiological problems. How could you treat properly the secretion of the digestive juices, the excretion of urine, the origin and distribution of animal heat, or even the problems of the central nervous system itself, if you were debarred from all reference to vaso-motor action? Try to withdraw from the web of to-day's physiology the thread of vascular contractility, and the whole tissue becomes a tangled skein. How, then, you may naturally ask, were those phenomena explained which we now so readily interpret as the results of vaso-motor action? Happy are you that you can now learn physiology without having your minds burdened with the ideas of determination of blood, nutritive force, capillary attraction, and other *Dei ex machina* called in to explain the facts which you unravel by help of the simple protoplasmic property of contractility.

Let me read you what the great anatomist and physiologist Johannes Müller wrote, just before Henle's discovery. I read from Baly's translation, which was not published indeed till after Henle's paper had appeared. "The old writers, and many recent physiologists, have erroneously regarded the contraction of the arteries which follow their dilatation as a muscular act, and have looked upon the fibres of the middle arterial coat as muscular fibres. But the fibres of the elastic coat of arteries differ, as we have already mentioned, from muscular fibres, both by their physical and chemical properties, as Berzelius has shown, as well as by their form. The different arguments for the existence of the pretended muscular contractility of arteries, which have

† Concluded from page 521 of last number.

been adduced from comparative and pathological anatomy, are of no weight." (Vol. i, page 214.)

Then, again: "Although it be denied that the circulation is in any way aided by an attraction between the blood and the capillaries, yet the existence of such an attraction or affinity may be admitted in the instance of the 'turgescence, turgor vitalis, or orgasm,' observed to take place in certain parts of the body, which are the seat of increased vital action, independently of the action of the heart. . . . This condition of vascular turgescence may be excited very suddenly, as is seen in the instantaneous injection of the cheeks with blood in the act of blushing, and of the whole head under the influence of violent passions; in both of which instances the local phenomena are evidently induced by nervous influence. The active congestion of certain organs—of the brain, for example—while they are in a state of excitement, is a similar phenomenon." (*Ibid.*, p. 239.)

Dr. Carpenter, in writing his first edition of his *Physiology*, from which I have already quoted, was aware of Henle's discovery; and we find him using the following language. "A very important use may be assigned to this muscular coat (of the arteries), which has been generally overlooked by physiologists: that of regulating the diameter of the tubes in accordance with the quantity of blood to be conducted through them to any part." (*Op. cit.*, page 411.) And again: "The minute distribution of the sympathetic nerve upon the walls of the arteries, the known power which this has of producing contractions alike in their fibrous coat and in the muscular tissue of the intestinal canal, and various phenomena which indicate the power of certain states of mind over the dimensions of the arteries, in particular parts of the body at least, render it highly probable that the calibre of the arteries is regulated in no inconsiderable degree through its intervention." (*Ibid.*, page 412.) In these words, you will readily acknowledge an anticipation of our more modern views; and yet, in spite of this, we find Dr. Carpenter, a little further on (page 415), relapsing into an enthusiastic support of the current doctrines of determination of blood, etc.

One man indeed, a man of great honour amongst us as the author of the cell-theory, I mean Schwann (who, in a few weeks, will receive public acknowledgment of his great services in the University which he has served now for forty years), had, some few years before, not only stoutly maintained, and, as he thought, experimentally proved, the contractility of the small arteries, but offered an explanation of vascular dilatation exceedingly like our present inhibitory doctrine. To his experiments, Johannes Müller replied with the dogmatic statement, that Schwann's results "could not be due to contractility of muscular fibres, because these did not exist in arteries". (*Op. cit.*, page 218.) And the physiological world in general went astray with Müller. A few scattered adherents may, from time to time, have more or less distinctly accepted Schwann's views, or something similar; but the vaso-motor doctrines now current cannot be said to have become part of general physiological teaching until after Bernard had, in 1851, called attention to the effects of division of the cervical sympathetic. As you already know, Brown-Séquard, in the following year, arrived independently not only at Bernard's result, that section of the sympathetic caused vascular dilatation of the ear, but also at the even more important result, unknown apparently at first to Bernard, that the dilatation and blush gave place to constriction and pallor when the peripheral segment of the divided nerve was stimulated; and our own Waller did much to put the whole matter in its proper light at an early stage of the discovery.

We may note here that, in this as in many other of Bernard's exploits, the discovery was, so to speak, "in the air"—it was waiting to be made. But is not this true of all discoveries? Are they not all "waiting to be made"? If Bernard had not made the observation, Brown-Séquard would; if Brown-Séquard had not, Waller would; if Waller had not, some one else would. As a matter of fact, Bernard was the first, and to him accordingly must the credit be given.

From this simple beginning, from this slight experiment, which you have now seen so often that you think nothing of it, has grown all our large body of vaso-motor physiology. And if I needed to give you any further proof of how essentially true it is that we owe this to Claude Bernard, I should only have to call your attention to the fact that it is to him again that we are indebted for the second great step in the progress of the doctrine. In 1851, Ludwig made the memorable observation that electric stimulation of the lingual nerve (or rather of the chorda tympani fibres running in the lingual trunk) called forth the activity of the submaxillary gland; but it was Bernard who, a little later, drew attention to the fact that the stimulation of the same fibres caused dilatation of the blood-vessels of the gland. He it was who first introduced the phrase "vaso-dilator nerve"; and I need hardly remind you what a crowd of ideas, some of them perhaps conflicting, but all illuminating, these words call up in the mind of the physiological student to-day.

But time is failing me; I must content myself with brief allusions to Bernard's other services.

It was in 1844 that he commenced his remarkable investigations on urari poison, though his observations were not published till 1850. The discovery of the action of this poison is perhaps typical of Bernard's work. It, like others, was a discovery "in the air"; for Kölliker, working quite independently, arrived exactly at the same result. Bernard's treatment of the question was characteristically his own. If you read his account of the matter, you will see how he gives way to exaggeration, and even to inaccuracies; and how he frequently fails to realise, or at least to show that he realised, the difficulties of his positions. In this respect, Kölliker's more cautious work contrasts favourably with his. But this must always be remembered of Bernard's apparent rashness. His speculations, even when hasty, were in most cases happy; his conclusions, even when not warranted by the evidence before him, have, not once or twice, but often, proved in the end, upon fuller knowledge, to be true.

And what shall I say of the importance of this urari discovery? Letting pass on one side altogether its effect in clearing up our notions of muscular irritability and nervous impulses, let me ask you to reflect on the service which has been rendered to physiology by a knowledge of the phenomena of urari poisoning, viewed as a mere method of research. If, at this moment, we were to blot out from our modern physiological science all that has been gained, directly or indirectly, by means of urari, what would come of it?

Such are some of the more important services rendered by Bernard to the science we are studying here. If I were to attempt to tell of all his work, from that first early memoir on the chorda tympani to that last work on ferments, in the midst of which death found and took him, not a single lecture, but almost a whole course of lectures, would be needed. I have narrated to you what I take to be his most important achievements. Remove these, and there are still left basketfuls of fragment—sufficient, I might say, to establish the reputation of a whole school of young physiologists. I might speak of his important work on carbonic acid poisoning; of his many papers on the submaxillary gland, in which, besides the capital fact of which I have already spoken, he pointed out the effects of reflex stimulation, the change of colour during activity, the so-called paralytic secretion, and contended for the autonomy of the submaxillary ganglion. I might speak, too, of his labours on animal temperature, starting with that early observation on the rise of temperature in the ear, following upon division of the cervical sympathetic, and continued till his last days. As you know, I am one of those who think that Bernard's, perhaps at present unwarranted, conclusion as to the existence of frigorific and calorific nerves, is precisely one of those which future researches will probably show to be eminently happy. If so, then we must simply double, perhaps more than double, the value which we have already attached to that pioneer experiment on the cervical sympathetic.

But I must stop. To tell of all Bernard's work, I should have to traverse the whole range of physiology. There remains, however, one feature of the man of which I must say one word. I began by telling you that he arrived at Paris a poet: he remained a poet to his death. A poet I mean, not in the sense that all scientific discoverers are poets, that it needs as fine a frenzy to pierce the darkness and unravel the perplexities of the entangled phenomena of what we call matter, as to fret about the troubles and longings of what we call spirit; but a poet, in the lower and more usual sense, that he was a phrase-maker. When you read his works, you will find yourself carried along by the flow of an easy diction, which seems to make everything plain; and every now and then you will come upon a phrase, the introduction of which is in itself equal almost in value to a discovery. You remember how, in our lectures here, we insist on the blood being regarded as the great "internal medium" on which, and in which, and by which the tissues live; you know that our teaching here is largely built up upon this conception. This picturesque and far-reaching phrase we owe, too, to Bernard. What, again, can be happier than his description of carbonic oxide poisoning as "a paralysis of the blood-corpuscles"? Other phrases of a like nature you will find scattered over Bernard's writings, some of them luminous in the highest degree, all of them happy and instructive.

Such is the story of Claude Bernard. I have not attempted to hide from you those things in which he fell short. I trust I have led you to feel how great was the work he did. Without exaggeration, we may say that his labours are *par excellence* the physiological labours of the middle third of the present century; and fortunate will be physiology if, when the century closes in, she can point to yet other later physiologists as having laboured with equal power, with equal diligence, and with equal fruit.

## FATAL CASE OF CARIES OF EXTERNAL MEATUS: OTORRHOEA AND SECONDARY AFFECTION OF BRAIN.

By F. M. PIERCE, M.D.,

Senior Surgeon to the Manchester Ear Institution.

THE following case contains some points of interest to the general practitioner as well as to the specialist. It is one of a class of cases, the termination of which is more frequently witnessed by the former than by the latter. In private practice, the earlier symptoms are often entirely overlooked, and the fatal result is attributed to any cause but the true one. The specialist, consulted by patients from a distance, is too far away to have the care of such a case in the last stage, and probably only learns the result by mere accident, long after it is too late to obtain *post mortem* proof of his diagnosis.

I was called about 3 A.M. on Tuesday, October 24th, 1877, to see a German gentleman, who had suffered from slight otorrhœa of the left ear on three or four occasions during the last six years. On these occasions, the discharge was slight and almost unaccompanied by pain, and did not continue more than a few days. The patient was a rather stout, stiff-built, apparently healthy man aged 56, of great muscular ability; there were, however, indications that in early years he had been very strumous (cicatrices of abscesses in the neck and of disease of the carpal and metacarpal bones), and had had syphilis.

On Saturday, October 20th, the patient complained of slight pain in the left ear, accompanied by otorrhœa. He did not pay much attention to these symptoms, which he had had on previous occasions without causing further trouble.

On October 21st, the earache and discharge gradually increased and prevented sleep.

October 22nd.—Though still suffering from pain in the ear and otorrhœa, with slight nausea, he persisted in going to business. During the day, he became very giddy, unsteady in his gait, had sharp pain over the left temple, and severe attacks of vomiting, which compelled him to return home, when his medical attendant, Dr. Gumpert, was called in. His pulse was then 120, and temperature 101 deg. Fahr. Towards evening, the pain and discharge were aggravated, but the retching ceased; the pulse, temperature, and respiration increased as the night advanced, and delirium set in.

About 4 A.M., Wednesday, October 24th, I saw the patient with Dr. Gumpert. He was then lying in bed, on his back, almost comatose, moaning, and constantly twitching the eyelids and face, and picking at the bedclothes. There was no ptosis or facial paralysis, and the pupils were equal and about normal. The skin was bathed in a cold clammy perspiration. The pulse 150, respiration 50. The temperature was not taken. In front of the left tragus, over the temporo-maxillary articulation, there was a hard tender tumour, like an enlarged gland, which had made its appearance within the last twelve months. The mastoid process was unaffected. On examining the left external meatus after removing a profuse collection of pus, an old perforation of the anterior superior quadrant of the membrana tympani was seen. It appeared clogged with thick muco-purulent discharge; and on exploring the meatus, a probe distinctly detected a small spot of carious bone on the anterior superior wall of the meatus, near to the membrana tympani. I immediately enlarged the opening in the membrane, by cutting upwards and downwards through a speculum with lateral aperture attached to Brunton's auroscope, and incised the walls of the meatus. The tympanic cavity was rendered thoroughly impervious by means of the Eustachian catheter, and ten leeches were applied in front of the tragus and behind the auricle. The patient gradually sank, and died at 10.45 A.M. the same day, October 24th.

NECROPSY, twenty-eight hours after death.—Blood was oozing from the left ear. On opening the skull, a large quantity of fluid black blood escaped from the cerebral sinuses, which were much congested, as were also the vessels of the dura mater, which looked opaque and thickened over the anterior half of the left hemisphere. On raising the dura mater, the whole surface of the anterior half of the left cerebrum, from about one inch from the longitudinal sinus down to the surface of the petrous bone was covered with thick yellow creamy pus. On careful examination of the cranial surface of the petrous and temporal bones, no caries or lesion could be detected to account for the purulent deposit. There was no abscess in the brain-substance, and no effusion into the ventricles. The temporal bone was not removed.

REMARKS.—There can be no doubt that many fatal illnesses, accompanied by convulsions, coma, and other cerebral symptoms constituting meningitis in one form or other, are due to undetected ear-disease. In this case, the fatal issue was very rapid, considering the

slightness of the premonitory symptoms. The existence of a perforation, evidently produced at some previous attack, tended to diminish the probable extension of the suppurative inflammation to the brain. How long caries of the wall of the meatus had existed is uncertain, whether coexistent with the first appearance of otorrhœa or with the last. If with the first attack, it is singular that signs of caries should have remained dormant so long; and if the last attack were the origin of the bone-affection, its rapid course is somewhat unusual. How did the pus reach the position in which it was found? We know that the upper wall of the external meatus is closely contiguous to the dura mater and cerebrum, but in this case there was no evidence of direct extension of the caries of the anterior superior wall of the meatus to the dura mater covering the petrous bone. Probably the pus was conveyed from the meatus by means of the smaller petrosal veins to the vessels of the dura mater. Branches of the middle meningeal artery pass in the adult from the dura mater to the tympanic cavity; and when we remember the pre-eminently vascular relations of the petrous bone with the cerebral meninges, we cannot be surprised at the frequent occurrence of embolism, abscess, thrombosis, and blood-poisoning from purulent ear-disease.

Professor Gruber points out that fatal ear-affections most frequently originate in disease of the external portion of the ear—meatus, etc.—and this case is certainly corroborative. Mr. Hinton says: "The fatal result is the consequence either of caries affecting the brain or vessels by continuity, or of poisoning through the veins of the diploë: or abscess may form in the brain in the neighbourhood of an inflamed tympanum without caries or any apparent means of propagation of the morbid action."

## A CASE OF CEREBELLAR ABSCESS.

By JOHN SERVICE, M.B.,

Assistant to the Professor of Clinical Medicine in the University of Glasgow, and Assistant-Physician to the Dispensary for Skin-Diseases.

THE following case, though not fully reported, may possess some interest.

Sarah H., aged 16, was sent into Belvidere Hospital on September 18th, as suffering from fever. An examination showed this to be incorrect; and at no subsequent time did she present a febrile temperature. Her history was as follows. Three months previous to admission, she began to complain of a slight, though constant, headache; and even before that, there were frequent attacks of giddiness. She never had had fits or convulsions. Her appetite had remained good; but the tongue became foul. A month after headache first began, a purulent discharge from the right ear made its appearance; and this, for a short time, is said to have given her a little relief. Soon, however, the pain returned as before, and gradually became worse.

On admission, her only complaint was of severe pain in the forehead and nape of the neck, and an inability to turn her head without great pain. The pupils were, if anything, slightly dilated. The tongue was covered by a white fur. The temperature was normal, and the pulse 80. The bowels were costive. After being ten days under observation (during which time purgation and blisters to the nape of the neck were resorted to), the patient said she was quite well, and was permitted to get out of bed. In two days more, however, she was worse than ever. The pain returned to the forehead. The pupils became very much dilated and immovable. Both eyelids drooped, and could not be completely raised; there was, therefore, ptosis. Her sight, too, was imperfect, but the power of vision varied in intensity at different times. Her tongue again became foul, and the bowels continued obstinately constipated. Twice, while at stool, she became giddy and fell forward, so that the use of the bed-pan was ordered. The temperature remained about 98.6 deg., and the pulse 60. Throughout, she remained in a drowsy state, and did not care about being disturbed. Her breath was very fetid; and for about a week before death (which took place on October 13th), there was a discharge of greenish matter from the nostrils. There was no paralysis of the limbs or anæsthesia; and she retained perfect control over speech. The heart-sounds were irregular and the second was accentuated.

To recapitulate: the leading symptoms, therefore, were persistent frontal headache, giddiness on standing, drowsiness, dilated and immovable pupils (both alike), partial ptosis, imperfect vision, and constipation. The treatment consisted of light diet, purgation, and blisters to the scalp. Transient relief was always experienced after the blistering. The iodide and bromide of potassium had also a trial.

At the necropsy (twenty-six hours after death), an abscess was found in the right lobe of the cerebellum, containing about three

drachms of greenish pus. The interior of the cavity consisted entirely of white brain-substance, and was of a firmer consistence than the rest of the brain. There were also in the cavity two small blood-clots, partially organised. The right lobe of the cerebellum was, comparatively speaking, a mere shell; and the left lobe, as well as the pons Varoli, was to a small extent also implicated. The membranes were perfectly healthy, and there was no apparent communication between the abscess and the suppurating ear.

## NOTES OF A CASE OF CARBONIC ACID POISONING, TREATED BY INHALATION OF OXYGEN :

WITH A DESCRIPTION OF A NEW APPARATUS FOR RENDERING IMPURE AIR RESPIRABLE.\*

BY CHARLES B. BALL, M.D.,  
Surgeon to the Blaenavon Iron Works.

ON January 16th, 1877, I attended a family who were found insensible in bed that morning. I found a man aged 55, his wife aged 48, and daughter aged 16, in one bed, in a very small room, quite insensible. There were the remains of a large fire in the grate, the chimney of which was imperfect. Upon admitting plenty of air and using the usual restoratives, the woman became sufficiently conscious to say that she remembered being up at 2 A.M., when she experienced considerable difficulty in breathing and a severe headache; after which she remembered nothing further till she was restored to consciousness. The man became semiconscious, but the girl remained perfectly insensible. I had her, therefore, removed to another and well-ventilated room, where artificial respiration was resorted to. She now had violent tetanoid convulsions, at intervals of a few minutes. The muscles of the face were, however, exempt from the general spasm. The pupils of the eyes were of average diameter, but dilated in bright light and contracted when the light was removed. This phenomenon was also noticed in the man's case.

During the day, the man and woman progressed favourably, but the girl became much worse, the convulsions appearing at longer intervals and the intervening coma being more profound. The treatment now adopted in her case was the application of a blister to the back of the neck, stimulating enemata, and the hypodermic injection of pure ether. None of these measures had the desired effect, and at ten o'clock that night she was apparently dying. The convulsions had entirely subsided. The pulse at the wrist could not be felt, and the respirations were few and shallow. Through the kindness of Mr. P. C. Gilchrist, F.C.S., I now obtained a large supply of pure oxygen, which, by a little arrangement of an ether-inhaler, I was enabled to give her to breathe in any degree of dilution required. At first equal parts of air and oxygen were given, but afterwards the proportion of oxygen was increased. It produced a rapid and most marked effect; the pulse soon became perceptible, and quickly increased in force. After the inhalation of about four gallons of gas, it was discontinued, respiration and circulation having been well revived. During the inhalation, the convulsions recurred, having been absent for several hours. Although not sensible during the night, she was decidedly better, being able to swallow fluid nourishment, and the convulsions gradually subsiding. She did not recover consciousness till the morning of the 18th, being forty-eight hours from the time I first saw her.

The different degrees in which the persons suffered, although exposed to the same poison, appears to be worthy of note. The intensity of the girl's symptoms is, I think, accounted for by the fact that she suffers from phthisis, and has therefore a smaller available lung-surface. As the woman got up to walk about the room during the night, she for the time respired a higher, and therefore purer, atmosphere; and this may account for the fact that her symptoms were the lightest of the three. The action of the pupils with regard to light, noticed in two of the cases, was remarkable and very apparent. Although the inhalation of oxygen has been recognised in medicine since the time of Sir H. Davy, yet its use amongst the generality of practitioners is not frequent, and the above case was the first time I have ever used it. Its action impressed me greatly; for I have never witnessed a life so certainly saved by any other therapeutic agent. One great objection to its more general use has been the difficulty of obtaining the gas readily, in a state of purity and in a portable form. This has now been obviated; and I have here a copper flask, into which fifteen gallons of pure oxygen have been compressed. I obtained it from Messrs. Barth

of 26, Duke Street, Bloomsbury, and it appears to be very convenient for medical purposes, being easily carried about, as its weight is only five pounds three ounces when full; the diminution in weight will tell roughly the amount of gas used.

From my experience in this case, I was led to the construction of an apparatus for obviating the bad effects produced by inhaling an atmosphere containing a large percentage of carbonic acid, by the simultaneous inhalation of an increased supply of oxygen; the applicability of some such apparatus being demonstrated by the experiments of Regnault and Reiset, who found that animals could live in an atmosphere containing a large quantity of carbonic acid, provided the percentage of oxygen was proportionally increased. The action of this apparatus is partially illustrated by the annexed diagrams. (Fig. 1.) It consists essen-

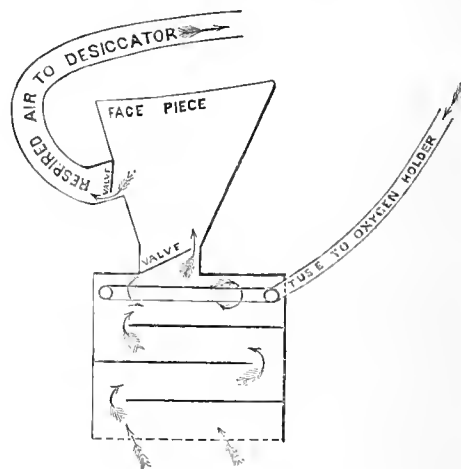

Fig. 1.

tially of a tightly fitting face-piece, which communicates with a chamber of a capacity sufficient for one inspiration. The chamber is separated from the outer atmosphere by a sheet of wire gauze, and the air is made to traverse several partitions. Behind the partition next the face-piece, oxygen is allowed to escape from a perforated tube, which is in communication with a reservoir, carried in the manner of a knapsack. The tube is supplied with a tap, which will allow the escape of

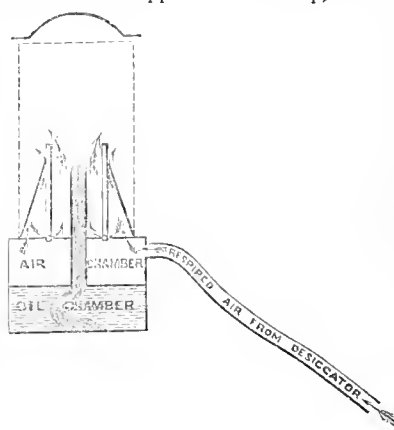

Fig. 2.

oxygen up to 30 per cent. of the air respired. During the intervals of respiration, the diaphragms will prevent the escape of oxygen from the chamber; and at each inspiration, the amount of oxygen required will be washed through the valve at the face-piece by the external atmosphere. The expired air is made by a system of valves to pass through an elastic desiccator, and thence supply a lamp. (Fig. 2.) By this means, the lamp can be made a guide as to the amount of oxygen required. By the use of this apparatus, I expect that a collier would be enabled to go into a mine charged with carbonic acid. In the case of an explosion, in which all the oxygen had been converted into carbonic acid and steam, the explorer would be enabled to supply himself with such an amount of oxygen as would neutralise the effects of the carbonic acid. The man could easily carry a supply of oxygen which would last for two hours, even when he was using the maximum quantity required; and, by connecting a second tube and face-piece to the oxygen-reservoir, he could revive any sufferer whom he might find overcome by carbonic acid. I may mention that, in the experiments connected with the construction of this apparatus, I have myself respired, without feeling any discomfort, during a considerable time, a mixture containing 18 per cent. of carbonic acid, but in which the

\* Read at the South Wales and Monmouthshire Branch.

oxygen was increased to 30 per cent. This amount of carbonic acid is 6 per cent. more than that found after colliery explosions in which complete combustion has taken place.

## THE TREATMENT OF ASCITES BY ABDOMINAL COMPRESSION.

By STEPHEN MACKENZIE, M.D.,  
Assistant-Physician to the London Hospital.

THERE are numerous ways of treating the ascites dependent upon contraction of the liver. Alteratives, drastics, diuretics, tonics, compelling the patient to satiate his thirst from his peritoneal cavity, simply keeping the patient at rest in bed, all have their advocates, and are plans under which I, as every other physician, have seen good results in even unpromising cases. Every now and then, however, under any of these plans of treatment, alone or in combination, the peritoneal effusion remains stationary, and its removal becomes tedious. I have found that, in cases where there is any tendency to absorption, this may be greatly accelerated by a simple method—that of abdominal pressure—to be described, and that in cases in which absorption does not appear to be taking place the same plan is often successful in removing the fluid. I have employed this treatment in several cases, with such good results, that it encourages me to hope that others will find it useful. Perhaps I can best illustrate the plan of treatment I have found so successful in some cases of ascites, by narrating the first case in which I put it into operation.

E. S., aged 41, widow, was admitted into the London Hospital under my care on January 16th, 1875. The patient stated that she had not been thoroughly well since her last confinement, nineteen years previously. About one year before admission, in January, she noticed that her waistbands became tight. She attached no importance to the occurrence, however, at first. In February and March, she found that she was passing extremely small quantities of urine. In May, the size of the abdomen was much increased, and its "weight" inconvenienced her when she moved about. The enlargement of the abdomen increased rapidly up to June, when she attended at another hospital as an out-patient. She then measured forty-two inches round the largest part of the abdomen. She attended for three months, and during that time increased in size, and continued to increase in size to the end of September, at about, she thinks, the rate of "an inch a month". Since September, the increase had been less marked, but had slowly continued, until coming under treatment. She had only passed very small quantities of urine. She was the mother of two children, and had miscarried once, owing, she thought, to a strain. There was nothing in her history to support the diagnosis of syphilis; no intemperance could be elicited on close questioning. She had never had jaundice. When admitted, I noted that the patient was much emaciated, but was not decidedly cachectic. The abdomen was greatly distended, of ovoid shape, tense, with extremely distinct fluctuation-wave. The circumference of the abdomen at the umbilicus was forty-six inches, and the same two inches higher. Medium-sized superficial veins were seen coursing over the abdominal walls from below upwards, as could be demonstrated by pressure. There were no veins passing downwards to the thighs; the umbilicus protruded slightly. There was oedema of the lower extremities, from the thighs to the feet, especially on the left side. There was a small patch of discoloration on the inner aspect of the left leg, which, she stated, had been in existence for five years. It came as a small speck of the same colour, and has gradually increased to its present size. There was no history of injury to the part; no nodes. Hepatic dulness in the right mammary line was bounded by the upper border of the fourth rib. Here and in the axilla it was about two inches in extent, and posteriorly on a level with the twelfth dorsal spine, it was four inches deep. The chest organs were pushed up, but presented no noteworthy signs. Vaginal examination showed the uterus and anterior wall of the vagina depressed (cystocele).

On January 22nd, the patient's expression was anxious. She complained of difficulty of breathing, and her respiration was seen to be embarrassed. There was a slight herpetic eruption around the mouth; the patient had not been observed to have a rigor since her admission, but was suffering from catarrh when she came. The bowels had acted daily; the motions were solid and of good colour. She passed about fifty-five ounces of urine *per diem*. It was of an orange colour, free from albumen and bile-pigment. She was ordered to take five-grain doses of iodide of potassium thrice daily.

January 26th. The patient had a less anxious expression, but still looked haggard and as if she were the subject of abdominal disease. The average quantity of urine was about seventy ounces *per diem*.

Her breathing was easier, but entirely thoracic. The measurement of the abdomen at the same point as before was forty-five and a quarter inches. The legs were less swollen than on admission.

February 2nd. Whilst the patient expressed herself as better, and appeared cheerful, she looked more haggard and pinched in the face, and had dark areolæ around the eyes. The sister stated that she began to sleep with her eyes open. The abdomen had considerably diminished in size, was quite lax, and fell over to the side on which she lay. It was forty-two and five-eighths inches in circumference at the level of the umbilicus. The superficial veins were not so distended. She took all the nourishment supplied to her.

February 12th. The patient appeared better. The iodine appeared to be producing toxic effects. She had an acnoid eruption on the face, and had watering and smarting of the conjunctivæ, running at the nose, and soreness of the mouth. She was ordered to discontinue the iodide of potassium, and to take a mixture containing citrate of iron and quinine.

February 23rd. The patient looked and expressed herself as better. She slept and ate well; she passed from fifty to sixty ounces of urine daily, which had a specific gravity of 1.016 to 1.020, and was free from albumen. The largest measurement of the abdomen was now thirty-nine and a half inches. The oedema had wholly disappeared from the legs.

March 30th. The patient's general condition was improved. The abdomen now measured thirty-six inches; its summit was about three-quarters of an inch above the level of the sternum, and it was flat on the surface. The edge of the liver could now be felt three inches below the point of the xiphoid cartilage. No irregularities could be felt on the surface of the liver.

May 11th. The condition of the patient appeared stationary. There was still a considerable amount of fluid in the peritoneal cavity. She passed about forty ounces of urine in the course of the twenty-four hours. *The abdomen was ordered to be tightly bound with a dannel bandage, so as to exercise pressure.*

June 4th. When the bandage was first applied to the abdomen the pressure caused a feeling of sickness, but soon the patient bore it without discomfort; in fact, it appeared to afford her relief. The measurement around the abdomen, at the level of the umbilicus, was now thirty-three inches. She passed about thirty to forty ounces of urine daily, and did not perspire much. I now ordered a properly made abdominal support to be constructed for her by the instrument-maker. It was arranged with straps, so that it could be tightened to a very considerable degree.

June 29th. The patient expressed herself, and appeared to be, in good general health, but she was still much wasted. The abdomen looked much smaller, and measured thirty-one and a half inches at the level of the umbilicus. There was pseudo-fluctuation on percussion, but it did not convey the impression of being due to fluid. The liver could be felt in the same situation as before. Its surface was smooth, its edge firm, sharp, and regular. The spleen was not to be felt in the abdomen. Its dulness reached the seventh rib in the axillary line. She passed, on an average, fifty to sixty ounces of normal urine daily. She ate and slept well. She was now allowed to get up, but was directed to continue wearing the abdominal support. The latter, owing to the diminution of the size of the abdomen, had required to be altered. After being up in the ward for a few days, the patient was allowed to go into the garden; and there then being no reaccumulation of fluid in the abdomen, she was made an out-patient. This was in July 1875. The patient has been continually under my observation from then until now. She has had no recurrence of the ascites. Her general condition of health is feeble, but she is able to do her household work and earn her living. Unusual exertion causes slight oedema of the feet. She has never had albuminuria.

Another case where equally good results followed, is the following. A. T., aged 46, married, was admitted into the London Hospital under my care September 3rd, 1875. She was quite well until two years before admission, when her feet began to swell. The catamenia, hitherto regular, at this time ceased. After the feet had been swollen two or three months, the abdomen began to swell; and it became so large that she came into the hospital eighteen months ago. She remained in the hospital three months, and during this time was twice tapped. On returning home, the swelling increased again, and she was again tapped. After this, the fluid again accumulated; she was readmitted into the hospital and tapped again. She improved, and continued as an out-patient until about eight weeks before her present admission, when her abdomen began to swell again, and it gradually increased, until she came into the hospital. There was nothing in her history to suggest syphilis; no excessive indulgence in alcohol could be elicited. The patient was a stout person, with injected cheeks, puffy face, watery and glistening conjunctivæ. The cardiac dulness could not

be mapped out; the impulse was indistinct; the sounds were natural; the lungs were normal, except for slight emphysema. The abdomen was much distended, of spherical form, rising three or four inches above the level of the sternum, and measured forty-seven and a half inches in circumference at the umbilicus. Fluctuation was distinct; the superficial abdominal veins were somewhat distended. The liver dulness appeared to reach the lower border of the fourth rib, in the right mammary line. Neither liver nor spleen could be felt in the abdomen. There was slight pitting on pressure over the legs. The urine was scanty, acid, of specific gravity 1.012, free from albumen. The temperature, pulse, and respiration were normal. The abdomen was directed to be bandaged with a wide flannel roller. She was ordered to take *mistura rubra*, one ounce, three times a-day.

November 15th. The ascites was considerably diminished. The abdominal walls were quite flaccid and thin. The liver-dulness did not extend two fingers-breadth in the right mammary line. The general condition was improved.

December 6th. The abdomen was greatly diminished in size; it was flaccid and pendulous. There was no distinct fluctuation wave now, but there was dulness in both flanks, whilst the summit of the abdomen was resonant. There was still slight pitting over the feet and legs. She was directed to continue the abdominal pressure.

December 20th. The patient was now up; the abdomen had not enlarged since she had left her bed. There was no oedema of the feet. She still had the kidney look observed on admission. For the last two months, she had passed, on an average, sixty-five ounces of urine daily, of pale colour, specific gravity varying between 1.010 and 1.015, and, though repeatedly examined, it had never contained albumen. The patient was now allowed to go home and attend as an out-patient. Whilst she continued under observation there was no recurrence of the ascites. The only medicine she took throughout her residence in the hospital was the *mistura rubra* of the *London Hospital Pharmacopæia* (burnt sugar and water).

It will be seen that in the first case alluded to the ascites was very great, and the vital condition of the patient brought very low from mal-assimilation. The appearance of the leg, with the absence of any history of intemperance (the latter not a very valuable indication in the case of a woman, it is true), suggested the possibility of syphilis causing the disease of liver which gives rise to the ascites. Without adopting this view, I thought it right to give the patient the advantage of the doubt, and accordingly administered iodide of potassium until the patient was fully under its influence. The ascites certainly diminished during the time the patient was taking the drug, but the diminution continued, it will be observed, when it was replaced by some quinine and iron, given as a general tonic, and was, no doubt, due to the rest in bed. I cannot ascribe any specific action to the iodide of potassium, therefore, and the patient never subsequently had any symptoms suggestive even of syphilis. Between March and May, it will be noticed, the patient made no progress. Her dropsy remained stationary. She passed at this time about forty ounces of urine daily. The idea suggested itself to me, as it had often previously, that the absorption which took place when the patient first came under treatment was due in great measure to the pressure of the greatly distended, tense, abdominal walls opening up the collateral channels of the portal circulation—the previously existing communications between the branches of the portal vein and the tributaries of the superior and inferior vena cavae, and the new system of vessels developed in the augmented connective tissue of the liver, and in the adhesions formed by this organ.\* When a certain amount of fluid had become absorbed, the abdominal walls became flaccid, and no longer exercised pressure on the portal system sufficient to drive the blood through devious and narrow conduits. It occurred to me to imitate the natural process by which absorption had, it seemed, been brought about in the first instance, and to the failure of which the arrest of the absorption appeared attributable. Hence I endeavoured by a bandage to convert the lax yielding abdominal wall into a tense elastic and resisting one. The employment of a properly constructed abdominal support was only a more convenient and efficacious method of applying the necessary pressure. The result was highly encouraging. The bandage and support certainly squeezed the fluid out of the peritoneal cavity, and it was carried out of the body, without loss to the system of any albumen, by means of the kidneys. The result was a cure of the portal obstruction. It is now nearly three years since the patient left the hospital, and I have had her frequently under my observation. There has been absolutely no recurrence of the ascites. Equally satisfactory was the effect of the same treatment in the second case I have given—a case from its

antecedents far from a promising one—and here the mechanical treatment was uncomplicated by the action of drugs. I may add I have had as good results in other cases.

Hitherto I have not tried abdominal compression in *increasing* ascitic effusions. It has seemed to me that the abdominal walls offered as much opposition to the pouring out of fluid as it would be safe to call into play, and that a greater strain on the vessels might lead to their rupture—effects we not unfrequently witness in cirrhosis, as hæmatemesis and hæmorrhage from the bowels. It is, however, quite possible that the obstacle offered to the effusion from the portal veins may be safely augmented to such a degree as to force open the anastomoses of the portal vein, and, by thus effectually carrying off the blood brought to the liver, to *cure the disease*. I use the word *cure* advisedly, as fibrosis of the liver in the main kills the patient by the secondary effects of the mechanical obstruction of the portal circulation. A person can get along, by management, with half a liver. In contraction of the liver, if the blood which cannot traverse the organ be efficiently carried off by other routes, and is not lost to the system, enough blood may yet pass through the liver to enable this large gland to perform its varied and important functions *for all ordinary needs* of the body. So far as I know, the plan of abdominal compression has not been recommended for cases of ascites, though I make no claim for its novelty. It has proved useful in my hands, and, I believe, will be found serviceable in causing or accelerating the absorption of an ascites, alone or in conjunction with other methods of treatment.

## TWO CASES OF POISONING BY PHOSPHORUS.

By FREDERICK W. WILLMORE, M.R.C.S. Eng., Walsall.

THE recent case of death from this poison, narrated in the JOURNAL by Surgeon-Major Martin, induces me to record two of a similar nature which have been lately under my own observation, and which present several features of interest. Two young girls, L. C. and M. H., aged respectively sixteen and fourteen years, took between them, on the evening of March 25th ult., a small potful of phosphorus-paste, containing about half-an-ounce. Vomiting, with abdominal pain, rapidly came on, yet no advice was sought for until the afternoon of Friday the 29th. I was then asked to see the sufferers, being told "that they had taken poison on Monday, in consequence of slighted affection, and that they were still lingering". In compliance with this quaint request, I at once saw the patients. Both presented symptoms of grave depression; the vomiting still recurred occasionally; there was no diarrhoea, but the whole abdominal region was greatly distended, painful, and tender. The breath and vomited matter smelt strongly of the poison, and the skin and conjunctivæ were both deeply yellow. Severe frontal headache was complained of, and the act of swallowing was attended with considerable difficulty and pain. The pulse was thready and easily compressed—in the elder girl 135; in the younger 98. From the first, the case of the former patient gave most cause for anxiety, and I ascertained that she had taken the larger amount of the poison. A small quantity of food and mucus, obtained from the stomach of M. H., and submitted to Mitscherlich's test, gave distinct evidence of the presence of phosphorus. The bowels having been gently cleared, small doses of morphia were given, with the effect of relieving the pain and vomiting. The case of L. C., however, rapidly became worse, the prostration more marked, and drowsiness and convulsions terminated her life on March 31st, eight days after taking her fatal meal.

On Tuesday, April 2nd, fifty-six hours after death, I made a careful examination of the body, of which the following is an abridged report. The stomach and bowels were greatly distended with flatus; the inner coat showing, over nearly its whole area, traces of recent inflammation, but destitute of any erosion. In the stomach itself was found a small quantity of black grumous material, with a distinct odour of phosphorus. The liver, though normal in size, presented changes of a striking character. It was of a dull yellow colour, its borders quite black, the dark rim varying from the eighth of an inch to nearly an inch in depth. Its under surface also presented black patches, contrasting strangely with the yellow body of the organ. This dark appearance seemed limited to the capsule, and did not extend to the parenchyma. The tissue itself was abnormally yellow, soft, and friable, and under the microscope its ordinary characters were quite indistinguishable. The gall-bladder was almost empty. The spleen contained a small cystic tumour, but was otherwise of the usual size and appearance. The cerebral membranes, and more especially the pia mater, were deeply hyperæmic, and the arachnoid space was filled with a considerable amount of effused fluid. The brain-substance was

\* Forrichs, *Disease of the Liver* (New Sydenham Society's translation), vol. ii, page 29.

softened, and the ventricles were distended with effusion. No morbid appearances were found either in the kidneys or bladder. This latter contained nearly a pint of limpid urine. All the remaining organs were healthy; the mouth and fauces not discoloured; nor was there any trace of ecchymosis.

The girl who survives yet maintains her yellow colour, with furred tongue and scanty excretion of urine; but in other respects she daily improves, and I hope will eventually recover. I may observe that she has been treated throughout with turpentine, and, in my judgment, with marked and continued relief.

Without wishing to comment unduly upon these cases, I may yet venture to remark one or two salient points in their history. The subacute symptoms, persisting for a space of nearly five days without materially alarming the relatives, are worthy of notice. Neither the pain nor the vomiting were of a severe nature; the bowels acted in an usual manner; and each of the patients, from time to time, took small quantities of support. Phosphorus is such an insidious and deadly poison, and in the form of paste is so accessible to the thoughtless and impulsive, that we may expect a recurrence of cases like the present. The symptoms produced by even a small dose of it are varied, and certainly not easily distinguishable; and it is only with the desire of adding some little corroborative testimony to Dr. Martin's interesting and instructive case that I have ventured to offer these few notes.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN AND IRELAND.

#### ST. BARTHOLOMEW'S HOSPITAL.

DR. MATTHEWS DUNCAN'S WARDS.

FOR the notes of the following case we are indebted to Mr. W. E. HUSBAND, Resident Physician.

*Fibroid Tumour of the Uterus proving fatal by Pressure on the Ureters.*—A. S. was admitted to the hospital on January 14th, with the following history. She had been married eleven years, but had never been pregnant. The catamenia commenced at twenty-one years of age. The last period commenced nine weeks before admission; it was very profuse, and accompanied by pain in the lumbar region and abdomen; it lasted thirteen days. The periods had generally been irregular; formerly, the intervals were frequently from four to six months. Two years ago, they became more regular, a scanty show appearing every three weeks. Six months later, the periods became profuse, with only a fortnight's interval. Latterly, there had again been a longer interval—four or five weeks; and the loss had been considerable.

On admission, she complained of a stabbing pain in the lower part of the abdomen, especially in the right flank, shooting down the thighs, and coming on every few hours. The cause of this pain was not suspected during life; but the necropsy showed that it was probably due to compression of the ureters by the tumour. She also complained of loss of appetite, constipation, and painful micturition, with great flow of water. The urine, when examined, was almost colourless, reaction acid, specific gravity 1003; it was free from albumen.

On examination, the abdomen was seen to be very prominent, semiglobose in shape, and occupied by a hard dense mass said to be of twelve months' duration. The most prominent point was midway between the umbilicus and symphysis pubis. The abdomen measured in girth 32 inches. The other measurements were as follows: from the navel to the ensiform cartilage,  $7\frac{1}{2}$  inches; to the symphysis pubis,  $8\frac{3}{4}$  inches; to the right superior iliac spine,  $7\frac{1}{4}$  inches; to the left superior iliac spine,  $7\frac{1}{4}$  inches. The whole of the prominent portion of the tumour was very hard and elastic. There was dullness on percussion over the mass up to one inch above the umbilicus, but no impairment of resonance elsewhere. *Per vaginam*, the true pelvis was found to be almost entirely occupied by a hardness which could be identified with the abdominal tumour above described. The vagina was natural, and contained a little white discharge. The sound passed easily into the uterus and to the left to the extent of six inches and a half. There was tenderness on both sides of the uterus, especially on the left.

Dr. Duncan thought that the pain might be diminished by relieving the great tension in the neck of the womb. The os was slightly open

and very much on the stretch, the tumour growing down into its lip on one side. He therefore incised the os with a pair of scissors, hoping to relieve the tension and pain, and to reduce the hæmorrhage, as in these cases is often found to follow the opening up of the neck. Two days after the operation, in the evening, a severe flooding suddenly came on, preceded for a few minutes by a sharp pain. The patient lost more than a quart of blood, the lips becoming completely blanched, and the radial pulse being imperceptible for a few moments. The flooding ceased as suddenly as it came on, and did not return till two days later, when in the middle of the day it commenced again, but was soon arrested by plugging the vagina. During the next eight days, she was troubled with uncontrollable vomiting, and no medicine had any effect in diminishing it. At the end of this period, she began to have frequent muscular twitchings, and later two actual convulsive attacks. She also had a limited herpetic eruption upon the perineum and labia; nowhere else. This came on suddenly, and disappeared almost as quickly. The patient died on February 3rd, the twitchings having gradually spread upwards, at last involving the face.

*Necropsy.*—The stomach was distended. There was no recent peritonitis; but there was evidence of old peritonitis, the upper surface of the liver and spleen being adherent to the diaphragm; but these organs appeared healthy. The right kidney was small and wasted; its capsule was easily removed, leaving the surface smooth, pale, mottled with a few blood-vessels; the cortex was diminished and white; the pyramids were pink; the ureter was much dilated and tortuous, nearly large enough to admit the finger. The left kidney and ureter were in the same state as the right. The kidneys weighed eleven ounces. There were no clots in the inferior vena cava or spermatic veins. At the junction of the left internal iliac vein with the external was a large fibrinous clot, not completely organised, but filling up the cavity of the vessel. On following the branches of the internal iliac vein, a branch was found coming from the spine and emptying into the obstructed vessel; it was completely blocked by a nearly organised clot. Filling up nearly the whole of the pelvis, was a large fibroid tumour weighing four pounds ten ounces, and pushing the bladder over to the left; it was covered by a thin muscular capsule. There was a large vein on the right side of the tumour, dilated, tortuous, and empty. The tumour was hard and pale, no blood-vessel being seen in its substance. The cavity of the uterus was displaced to the left; it was very elongated and dilated, and very pale; the cervix was obliterated. The right ovary was very pale. The mucous membrane of the bladder was very pale. It appeared that the tumour had been jammed into the pelvis and compressed the ureters; these, becoming greatly dilated and tortuous, irritated the kidneys, and their substance became diseased. The nervous phenomena referred to were uræmic, due to compression of the ureters. The urine, when examined, had a low specific gravity, but was free from albumen. As it was passed involuntarily, it could not be re-examined.

*Operation for Removal of a Uterine Polypus.*—A woman, the subject of uterine polypus, came to the hospital for its removal. A large mass was felt projecting into the vagina, but neither the finger nor the uterine sound could be passed beyond the tumour to ascertain exactly its connection. Dr. Duncan referred to the importance of exact diagnosis before operation in these cases, instances having occurred in which an inverted uterus had been cut off under the impression that it was a polypus.

The patient being placed in the lithotomy position, the tumour was seized with a volsella, which was then brought downwards and forwards against the pubis; a second volsella was then used to catch the tumour at its posterior part and drag it near to the orifice. Digital examination revealed a distinct and firm pedicle, half an inch thick and about an inch and a half long, which passed up into the uterus, and the sound passed without difficulty the normal depth into the uterus. A strong pair of curved scissors was used to divide the pedicle; the operation was quite painless. The uterus itself appeared perfectly healthy, and contracted immediately after the operation, so that the stump of the pedicle could no longer be felt.

On examining the tumour removed, the pedicle, which had been cut at least an inch from its extremity, no longer projected from the tumour, but had shrunk into its mass. The tumour measured three inches in diameter; it was nodular and inflamed upon the surface, a condition not usually seen in its structure it appeared fibroid.

*Parametritic Induration.*—In seeking evidence by physical examination upon which to found a diagnosis in another case, Dr. Duncan commenced by examining the abdomen. Nothing abnormal was felt, but there was some fullness in the hypogastrium, about the region of the brim of the pelvis; in this locality the abdominal wall could not be depressed as easily as should be. In this case, as is usual in well-formed women, the promontory of the sacrum could be easily felt lying but a

short distance behind the anterior abdominal walls. This fact is of importance, as affording the means of estimating the sacro-pubic diameter for obstetrical purposes.

Examination *per vaginam* indicated the uterus to be in its natural position, while a hard mass was felt to the right side below the position of the cervix; it appeared to be identified with the upper and internal margin of the obturator foramen.

The bimanual method of examination was then used; the left hand being placed upon the abdomen, while the internal examination was continued; it was thus made out that there was no tumour in the pelvis.

Dr. Duncan remarked that, as there is no peritoneum in connection with the descending ramus of the pubis, where the induration was felt, the condition present could not be due to pelvic peritonitis. The symptoms of the case indicated chronic disease rather than acute, and there were no signs of suppuration. It appeared probable that the induration felt began in the bones or glands of the pelvis, as the uterus appeared to be healthy. There was, therefore, reason to fear that the disease was malignant.

It was subsequently discovered that the patient had intestino-vesical fistula: air passing through the urethra. This circumstance, together with the great degradation of general health, confirmed the diagnosis of malignant disease.

*Cauterisation of Epithelioma of the Uterus.*—A woman, the subject of epithelioma of the cervix uteri, was brought into the theatre for operation. The thermo-cautery was used. For this operation, Dr. Duncan prefers a boxwood speculum, as the glass-tube may be broken by the heat of the cautery, or may so conduct the heat as to injure the patient. The cervix having been carefully dried after the insertion of the speculum, the cautery was freely applied to the diseased surface; the parts were then well syringed, and a plug of carbol oil was inserted. By this means, the area of ulceration and the amount of discharge might be temporarily diminished.

#### SAMARITAN FREE HOSPITAL.

##### CONSULTATIONS.

APRIL 12th. *Ovarian Tumour complicated with Uterine Outgrowth and Mucous Polypus in Cervical Canal.*—E. R., a single woman, aged 57, noticed in November 1877 that her abdomen was increasing in size. It has steadily continued to enlarge ever since. The catamenia ceased six years ago, after being excessive for eight previous years. Fifteen years ago, an uterine polypus the size of a duck's egg had been removed by ligature. She now has a large cystic tumour of the abdomen, which appears free from adhesions; also a hard nodular mass in the pelvis, lying behind and to the left of the cervix. A small mucous polypus protrudes from the cervical canal. In submitting this case to his colleagues for their opinion, Mr. Knowsley Thornton expressed his belief that a large free ovarian tumour existed, that the uterus was retroverted with subperitoneal fibroid outgrowths on its surface, and that a mucous polypus grew from its cervix. He proposed to perform ovariectomy, taking the opportunity of confirming the diagnosis as to the uterine condition. As the cervical polypus was giving no trouble, he did not propose to remove it till after the patient had completely recovered from the major operation.—Dr. Greenhalgh agreed both as to the diagnosis and treatment.—Mr. Spencer Wells admitted that the abdominal tumour was ovarian, but was of opinion that the pelvic tumour was also an enlarged ovary. He considered it immaterial whether the polypus was twisted off at once or left alone.—Dr. Day believed the cyst in the abdomen to be ovarian, and the tumour behind the cervix to be a subperitoneal fibroid growth.—Dr. Champneys and Mr. Meredith were of the same opinion.—Mr. Doran also believed in the coexistence of an ovarian and an uterine tumour. He thought that the avulsion or ligature of the polypus in an uterus otherwise unhealthy was attended with considerable risk. He had recently made a *post mortem* examination of a case of large fibroid tumour of the uterus where fatal pyemic symptoms had followed the removal, by twisting, of a small mucous polypus. He found a recent abscess in the right ovary, and another in the broad ligament; whilst the right ovarian vessels lay in a pool of pus as far as their junction with the aorta and vena cava.

*Abdominal Tumour of Uncertain Nature.*—S. F., aged 50, single, catamenia absent nearly two years, had enjoyed good health up to July 1877, when she found that her abdomen was enlarging. An attack of diarrhoea came on, with much abdominal pain, which lasted two months. The enlargement continued. In February 1878, she went into St. Bartholomew's Hospital, where she remained for a month. She has now considerable swelling of the abdomen, which is anteriorly rather flat as she lies on her back. The skin is dry and rough; the superficial veins and capillaries are enlarged; but the abdomen is not

tense. Dulness extends from the pubes to the ensiform cartilage in front; but the percussion-note is clear in both flanks. The uterus is small, mobile, and slightly displaced to the right; and an indefinite swelling is felt to the left and in front of that organ. Mr. Thornton was not prepared to give a positive diagnosis. If the case were ovarian, he thought it must be a tumour with universal parietal and some intestinal adhesions, or a ruptured colloid tumour with matting and adhesion of intestines. He thought, however, that it very probably might be a case of encysted peritoneal fluid resulting from chronic peritonitis. He was prepared to recommend a small antiseptic exploratory incision, and to proceed with caution. If it turned out to be a collection of fluid due to peritonitis, he considered that a cure might be effected by removing the fluid and lymph and thoroughly sponging the cavity antiseptically. Of course, if he found the tumour to be ovarian, he would remove it.—Dr. Greenhalgh believed that an ovarian tumour existed, evidently adherent to surrounding structures, since there was so little mobility.—Mr. Spencer Wells considered that the swelling was a cyst of the ovary adherent at the upper part to the abdominal parietes.—Dr. Day thought that the history, appearance of the case, and physical symptoms, all pointed to ovarian disease.—Dr. Champneys, bearing in mind the history of two months' diarrhoea and abdominal pain, and laying stress on the great want of mobility of the tumour, thought that the suggestion of a large circumscribed collection of fluid due to peritonitis was correct. By rectal examination, he believed he could detect the left ovary, apparently distinct from the pelvic swelling, close to the uterus.—Mr. Meredith considered that the symptoms indicated strongly the existence of an adherent ovarian cyst, very probably of a colloid nature.—Mr. Doran believed that the abdominal tumour was an enlarged right ovary. By simultaneous digital examination of the vagina and rectum, it seemed to him that the pelvic swelling was a diseased left ovary.

#### HEREFORD COUNTY AND CITY ASYLUM.

##### DISPLACEMENT OF LIVER BY DILATED SIGMOID FLEXURE.

(Under the care of Dr. T. A. CHAPMAN.)

J. B., a deaf-mute, died April 6th, 1878, aged 58. On *post mortem* examination, April 8th, the sigmoid flexure of the colon was greatly distended and enlarged. On opening the abdomen, it had at first sight all the aspect of the stomach, both as to appearance and size, and suggested that the case was one of transposition of the abdominal viscera. A further examination showed the enlarged viscus to really closely resemble a large stomach, both in form and appearance. When removed, it showed none of the muscular arrangement of the walls of the colon, but an uniform muscular coating; its circumference was fourteen inches, with a larger curvature of twenty inches and a smaller of ten or twelve. The descending colon passed to the right into this expansion, and the continuation to the rectum was behind and to the left of this. At the pelvic brim was a constriction, to about three inches in circumference, and, from the thickening of walls, probably the seat of old inflammatory changes; the mucous membrane here was much inflamed, the rectum was narrow, but healthy. The most remarkable point in connection with this dilated viscus was its position, viz., between the diaphragm and the right lobe of the liver, which, instead of being full and convex and applied to the diaphragm, presented a great hollow, measuring six inches backwards from the anterior margin of the liver. The liver weighed thirty-six ounces.

#### NOTES ON BOOKS.

EVERETT'S *Elementary Text-Book of Physics* (Blackie and Sons, London and Edinburgh) is a highly commendable book; it is concise, clear, well systematised, and adequately illustrated. It is a very useful and satisfactory text-book for elementary classes.

*Practical Gynecology: a Handbook of Diseases of Women.* By HEYWOOD SMITH, M.D. (J. and A. Churchill, London.)—The fault of this little book is excessive condensation, which reduces it in many parts to the character of a mere catalogue, and that of an incomplete kind. On the other hand, it is an useful *aide-memoire* to the practitioner and student who has already acquired adequate knowledge of a subject and requires refreshing. It is obviously the work of a thoroughly intelligent practitioner well versed in his art, and perhaps only too prone to give his readers credit for more knowledge than ought to be credited by the author of such a compendium to those who wish to make use of it. We expect to see this little book reach its second edition, and should advise its extension with a view to greater completeness.

# GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION. SESSION, 1878.

Wednesday, April 10th, 1878.

DR. ACLAND, President, took the chair at 2 P.M.

*New Members of Council.*—The official notices of the appointments of the following members having been read, they were severally introduced and took their seats:—Andrew Fergus, M.D., Crown Nominee for Scotland, in place of Joseph Lister, M.B., resigned; James Bell Pettigrew, M.D., Representative of the Universities of Glasgow and St. Andrew's, in place of Allen Thomson, M.D., resigned; Robert Scott Orr, M.D., Representative of the Faculty of Physicians and Surgeons of Glasgow, in place of John G. Fleming, M.D., resigned.

*President's Address.*—The PRESIDENT delivered an address, which was published at page 543 of last week's BRITISH MEDICAL JOURNAL. At its conclusion, it was moved by Dr. ANDREW WOOD, seconded by Mr. SIMON, and agreed to, "That the President's Address be entered in the minutes".

*Committees.*—The Business and Finance Committees were appointed.

*Order of Business.*—Various questions were asked of the PRESIDENT relating to the order and nature of the business that would come under the notice of the Council, and to what would be the probable length of the present session.—The PRESIDENT referred to the programme, which stated the order of business as prepared by the Executive Committee. The Council would, it was hoped, follow the order of that programme. The second reading of the Government Bill was to take place on Monday next. Any resolution the Council might desire to forward to the Government before the second reading would, therefore, have to be decided before the Council rises on Saturday. No other limitation could be imposed on the liberty of the Council's action, except by resolution of the Council.

*The Medical Acts Amendment Bill.*—The following letter was read from the Lord President of Her Majesty's Privy Council, accompanying copies of a Bill entitled An Act to Amend the Medical Act (1858), presented by the Lord President.

"Council Office, March 23rd, 1878.

"Sir,—I am directed by the Lord President of the Council to transmit to you fifty copies of the 'Medical Act (1858) Amendment Bill', now before Parliament. The Lord President instructs me to request that you will be so good as to favour his Grace with any observations the General Medical Council may have to offer in regard to the provisions of the Bill.

"(Signed) C. L. PEEL.

"H. W. Acland, Esq., M.D., F.R.S."

*The Royal College of Surgeons of England and the Medical Acts Amendment Bill.*—A report was read on the Medical Acts Amendment Bill, which had been drawn up by the President and Vice-Presidents of the Royal College of Surgeons, after consultation with the two members of the Council of the College who are also members of the General Medical Council (Sir James Paget and Dr. Humphry); also a series of resolutions founded on the report and adopted by the Council of the College. (The resolutions were published at page 545, column 1, of last week's JOURNAL.)

*The Royal College of Physicians of London and the Medical Acts Amendment Bill.*—A memorandum was read which had been agreed on at a special meeting of the Royal College of Physicians of London. It stated that "the College desires to express its extreme regret and disappointment that the Bill altogether fails to provide for that compulsory establishment of conjoint examining boards for each division of the United Kingdom which was recommended and urged on the medical authorities by the General Medical Council, for which the College has been strenuously labouring during many years, and which constituted the main feature of Lord Ripon's Bill. For the attainment of this object, the College has spared neither time nor labour; has manifested its readiness to sacrifice its own individual interests and independence of action, and has loyally co-operated with the other English authorities, believing that by so doing it was acting in the common interests of the profession and for the good of the public. But this object, admitted on all hands to be of supreme importance in any scheme of medical reform, would certainly be hindered rather than advanced should the present Bill become law. Far from encouraging the English authorities to bring into operation the scheme which, after long and unremitting efforts and overcoming innumerable difficulties,

they have completed, and were prepared to make trial of, this Bill would compel them to abandon the scheme, and all hope of reaping any fruit from their labours." To Clause 3,\* it was objected that "it not only deprives the present licence of the College of its double qualifying power, but also deprives the membership and fellowship of the College of the qualification to register unless accompanied by some other qualification. That the College of Physicians is, by this clause, really disfranchised is proved by the third schedule of the Bill, which repeals the Act 32 Henry VIII, c. 40, by which the words of the College Charter are defined as conveying a right to practise both medicine and surgery." Of Clause 8 the College could not see the object, since, "by Clauses 5, 6, and 7, provision is already made for the registration of both foreign and colonial practitioners; and the College has by by-law provided for the admission of foreign and colonial graduates on terms similar to those on which graduates of British Universities are admitted to its qualifications". Clause 9 "makes no provision for a separate list of female practitioners". The effect of this, taken in connection with subsection 4 (b) of Clause 14, "will be that in the same list will appear the names of both men and women, although their respective tests of fitness may be unequal". Clause 14, relating to examination-rules, is regarded as "a disfranchising clause". It "deprives the College of the right of fixing its own standard of fitness for the reception of its diplomas, and of regulating its own examinations. It even confers on the Privy Council the important function of determining on the admission of candidates to examination, i.e., of laying down the curriculum of study; it deprives the medical authorities of all discretion as to the requirements requisite for their several diplomas, and, whilst it requires the several authorities to confer their licences, it deprives them of the power of determining the conditions on which they are granted, and so deprives each diploma of its distinctive value, and reduces all to one dead level, to the manifest injury of the College, by destroying the prestige of its qualifications, hitherto held in the highest estimation. To a power of supervision by the General Medical Council, a body eminently qualified to judge of such matters, the College could have no objection, and would even consider it desirable that such a body should have authority to secure the efficiency of rules for conducting the examinations, and a proper standard of fitness for reception of the several diplomas. But the initiation of such rules, and their adaptation to the respective diplomas, should remain in the hands of the several authorities. If, indeed, conjoint examination boards were made compulsory for each division of the kingdom, with the view to the granting of a minimum qualification, the College of Physicians would doubtless be ready to co-operate with the other authorities, and sacrifice its individual action for the common good, retaining, however, its independent action in respect of its higher qualifications". Under Clause 17, "a person whose name appears in the certified list of those who have passed the examination of a medical board is entitled to receive from any medical authority party to the scheme a medical diploma; but, under section 4 of Clause 14, it is clear that women may go up to any examination of a medical board, although not necessarily (a) to the separate examination of any one medical authority. A woman, therefore, who had passed the examination of a medical board would be placed on the certified list, and so become entitled to a medical diploma. If the right of a woman who has passed the examination of a medical board to claim a diploma be absolute, then some provision should be made for distinguishing such diploma and placing it on a separate register, as well as for distinguishing between the examination-rules of men and women."

*The British Medical Association and the Medical Acts Amendment Bill.*—The following letter to the President from the Chairman of the Medical Reform Committee of the British Medical Association, and the President's answer thereto, were read.

"14, Nicholas Street, Chester, March 30th, 1878.

"Dear Dr. Acland,—In the present conjuncture of medical politics, I venture to submit to your careful consideration, as President of the General Medical Council, the Medical Acts Amendment Bill, approved and promoted by the British Medical Association. This Bill, amended as it would necessarily have been in its passage through the legislature, would, I believe, have been infinitely more acceptable to the profession and more beneficial to the public than the present Bill of the Government. I enclose with the Bill of the Association some of the reports of the Committee. The division of opinion between the General Medical Council and what is regarded as the profession in the matter of medical reform must be detrimental to the real interests of the profession which we all have so earnestly at heart. Is there no possibility of reconciling the different views held by each party, so that we

\* As for recent reference will be made to the clauses of this Bill in this report of the proceedings of the Medical Council, we beg to remind our readers that it was printed in full at page 426 of the JOURNAL for March 23rd.

might with one accord urge the Government to grant the prayer of the profession? (Signed) EDWARD WATERS, Chairman of the

Medical Reform Committee of the British Medical Association.  
"Professor Acland, M.D., F.R.S., Oxford."

"Oxford, April 3rd, 1878.

"Dear Sir,—I have to acknowledge the receipt of your letter on the subject of the amendment of the Medical Acts, together with the enclosures; viz., a Medical Bill (1876) and three other printed documents relating to changes in the Medical Acts. They shall all have my best attention. I trust with you that legislation may be able to rectify any anomalies or defects which can give just ground of dissatisfaction in respect of the Medical Acts. I am confident that you may rely on the best efforts of the Medical Council in endeavouring to ascertain what that legislation should be, and in seeking to bring about a successful issue. (Signed) H. W. ACLAND.

"E. Waters, Esq., M.D., Chester."

*Conjoint Boards.*—Sir WILLIAM GULL asked the PRESIDENT "what progress had been made in the matter of a conjoint scheme for a common examination in Scotland and Ireland".—The PRESIDENT answered that no information on this subject had, so far as he knew, reached the Council.

*The Medical Acts Amendment Bill*, introduced into the House of Lords by the Lord President of the Privy Council, was taken as read and ordered to be printed as an appendix to the minutes.

*Conjoint Examining Boards.*—Dr. HUMPHRY moved: "Whereas, in 1870, this Council passed the following resolution by a large majority, and after much deliberation: 'That this Council is of opinion that a joint examining board should be formed in each of the three divisions of the kingdom, and that every person who desires to be registered under any of the qualifications recognised in Schedule (A) to the Medical Act shall be required, previously to such registration, to appear before one of these boards and be examined in all the subjects which may be deemed advisable by the Medical Council; the rights and privileges of the universities and corporations being in all other respects the same as at present; and whereas the Council has subsequently sanctioned a scheme for an examining board for England made in conformity with that resolution: the Council adheres to the principle of that resolution, and is of opinion that no medical legislation relating to examinations will be satisfactory which does not provide for the formation of an examining board in each of the three divisions of the kingdom, and direct that every person who desires to be registered under the Medical Act shall be required to appear before one of these boards and be examined in the subjects which may be deemed necessary by the Medical Council.'

Dr. HUMPHRY said that the Medical Acts Amendment Bill omitted to carry out the plan proposed and insisted on by the Medical Council, and it was the first duty of the Council to express a decided opinion with reference to the principle of the formation of a single examination board for each division of the United Kingdom. The Council was never called on to decide on a more important matter: it was one on which the confidence of the public in the Council would rest. He hoped that every member would take a broad view of the question. He would enter slightly on the history of the subject, especially for the information of the new members. In 1869, a report of a committee of the Council, of which Dr. Andrew Wood was chairman, contained a sentence to the effect that the time had arrived when the Council might enter on the consideration of the formation of single examining boards in each division of the kingdom, before which every candidate for admission to the medical profession should be required to appear, it being left optional to proceed afterwards to the higher degrees and diplomas. The consideration of the report was deferred to the next year, and in the meantime it was sent to the various examining bodies for their opinions and suggestions. In 1870, the report, with the replies received, was discussed; and a resolution, proposed by Dr. Parkes, and seconded by Dr. Thomson, in favour of the formation of conjoint boards, was carried by a majority of the representatives in the Council from all the divisions of the kingdom. The Council went still further, and passed a resolution, in accordance with the foregoing one, that "The universities and medical corporations established in each division of the United Kingdom shall be requested to concert a scheme for the constitution and regulation of a conjoint examining board for that part of the kingdom to which they belong, and shall transmit such scheme for the consideration of the General Medical Council." They also resolved to seek from the legislature the powers required for carrying the resolution into effect. The members would thus see that the Council had originated the principle of single boards, had endeavoured to bring it into action, and had requested the Government to bring in a Bill containing the necessary provisions. The medical authorities of England at once set to work and framed a

scheme, which had received the approval of the Council; and they had drawn up a series of regulations, which were nearly ready to be brought into operation. The English authorities had been taunted with the difficulties with which they had met and with the slowness of their progress; but every good and great work was attended with difficulty. He (Dr. Humphry) could speak of the difficulties which had been met with, having been more engaged perhaps than any other member in the preliminary proceedings. He had been engaged in it as a member of the Council of the Royal College of Surgeons of England, a body which had probably greater interests at stake, and superintended the education of more students, than any other. It would, then, not be wonderful if it should hesitate to give up its privileges and its opportunities of doing good work. He had also been engaged in the consideration of the conjoint scheme on the part of the University of Cambridge, which took a great interest in medical education, and had a medical school. Both these bodies entered on the scheme from the feeling that a great national good was to be attained, and this feeling had carried them through all difficulties almost to the climax of success. But the greatest difficulty was the apprehension lest the good work should fail from want of co-operation in the other divisions of the kingdom. The question to be now considered was, whether the Council would stand true to itself and to the English examining bodies, or, by setting aside its former resolution, stultify itself and leave them in the lurch. Were the circumstances different now from what they were when the resolutions were passed in 1870? It was then felt that the power of obtaining a licence to practise from any one of nineteen separate boards was an anomaly, and that the diploma or licence should cover the whole range of medicine. That reason still remained in full force. It might be said that the evils referred to might be remedied by the visitation of examinations. Visitation had indeed done much good, but, as applied to the nineteen examining bodies, was an exceedingly cumbrous and costly process, and could only be carried out effectually in ten or fifteen years. This had been acknowledged by the Council. But there was also the disadvantage of the imputation, arising from the financial interest of the corporate bodies in the examinations, that there was a downward competition among them, and that candidates rejected by one board might soon afterwards be admitted by another. He had been recently told that students, whose teachers would not certify their fitness to undergo an examination, had gone to other boards and obtained their diplomas. Such imputations ought no longer to be allowed to exist. The qualification should be obtained on such terms as to remove all ground for them. The objections to the principle of single boards came mostly from Scotland. One was, that the principle did not assure uniformity of qualification. But it would do this six-fold, by establishing three licences in place of nineteen—one for each division of the kingdom; and these examinations would be conducted, not by bodies having a financial interest in the matter, but by a combination of bodies which would receive as a whole the fees that might be paid, and hence there would be no downward competition. It was also objected that the plan of single boards would lead to too much uniformity. No doubt it would lead to a considerable amount of uniformity of examination; but there was an apprehension in Scotland that it would bring down university education to a low level. There was no reason to fear this. The English universities had entered into the scheme without fear of any lowering effect on the examinations for their degrees, and had taken precautions which the Scottish universities might also adopt. The state of the matter was this: the uniform examination would go no further than was sufficient for a simple qualification to practise, and the colleges and universities would be left free to make their own regulations for their higher degrees and diplomas. In England, the universities felt that it was an advantage to be relieved from the task of giving licences to practise, and from the necessity of preventing their requirements from being so high as to debar a candidate from obtaining a licence on which his daily bread might depend. The same was applicable to the universities of Scotland; instead of a conjoint scheme bringing down the standard of medical education, it might be made to act in the opposite direction. It has been said in Scotland that a conjoint board could not be formed there; but "cannot" was not a word for Scotland to use. It was said in Scotland that a difficulty would lie in the necessity for bringing together the candidates from all parts; but in England candidates constantly came to London from Newcastle, Liverpool, Bristol, and other distant schools. The examinations, too, might be held in different parts. Indeed, the Scottish bodies might overcome the difficulties if they would endeavour to do so. One difficulty alleged in Scotland was the effect which a conjoint board would have on the various examining bodies; but the Council should not be influenced by this: its chief duty was to act for the advantage of the public no less than of the profession, whatever feeling it might entertain towards

the examining bodies. The resolution which he proposed urged legislation on the subject of single examining boards. He would refer to the correspondence with the Marquis of Ripon in 1870. There was then scarcely any question as to the propriety of the proposed enactment, and he was astonished to find that the principle had been abandoned in the present Bill. This, he understood, had been done through the influence of Scotland. He did not object to Scotland doing its best, but it was the duty of England to stir itself, and take care that the principle was not squeezed out by the grasp of Scotland. In the Bill a twofold plan was adopted. First, means were taken in Clause 3 to secure a double qualification in medicine and surgery. This would be better than no provision at all; but what endeavour was there to secure uniformity? A plan was proposed, under which, if it passed, no single body could grant a degree, diploma, or licence except under rules framed by the General Medical Council and approved by the Privy Council; and further, power was given to the Privy Council to modify and alter the examination rules. There could be no comparison between the sacrifice of independence here entailed, and the maintenance of independence in the licensing bodies under the plan proposed by the Council. He had been largely engaged in the proceedings of the Committee of Reference which had met to frame rules for the conjoint board for England, not with reference to this or that corporation or university, but for the purpose of instituting the best plan of education and examination. He wished that some of the Scottish members had been present at some of the conferences; they would have seen the advantages of meeting and of discussing these difficulties, so as to overcome them. The Bill gave the Privy Council more power than before, and he trusted that the Council would not allow the power of the profession to regulate its own affairs to be encroached on. He trusted that the Council would stand to its own colours, and insist on the principle of a single examination in each division of the kingdom.

Sir JAMES PAGET seconded the motion.

Dr. ANDREW WOOD said that he had been at first much taken with the idea of single boards, but in a short time he found reason to believe that it would not be beneficial, and that the ends which were proposed would not be gained. He did not lay much stress on difficulties in Scotland; but, when Dr. Humphry considered that a conjoint system was the right one, he (Dr. Wood) thought that the object could be better carried out in other ways. The Council should be at liberty to discuss the question as if it were entirely new. What was the present condition of the medical profession? Were there many evils, and, if so, what remedies ought to be applied? He would go back to the period before the Medical Act was passed. Why was medical reform demanded? No doubt in consequence of the existence of a large number of bodies without any controlling power over them, each body making its own regulations, these being consequently very unequal, some being good and some bad, and scarcely any coming up to the proper standard. There were also the partial qualifications, under which members of the College of Surgeons, or licentiates of the Society of Apothecaries, might practise in all departments of the profession, though holding only a qualification in surgery or in medicine. It was a defect in the Medical Act of 1858 that there was no power to prevent the registration of men holding single qualifications. An attempt was, indeed, made to remedy this by giving power to the bodies to combine, and it was doubtless expected that they would take advantage of this. But it was done in Scotland alone. Again, before the passing of the Act there was little or no examination in general education; there was no *Medical Register*, and consequently no means of distinguishing qualified from unqualified practitioners, and there were invidious local restrictions on medical practice. The existence of these conditions led to much agitation for medical reform—for the removal of local restrictions, for the establishment of a general standard of qualification, and for the establishment of a Medical Council. Bills were brought into Parliament year after year by very able men, but legislation was obstructed by various impediments. One was the difference of opinion as to the real essentials of medical reform. Another was the existence of feuds between the licensing bodies. Another impediment arose from the difficulty of agreement as to the constitution of the Medical Council. Some proposed that it should be nominated by the Crown; others, that it should be appointed by the licensing bodies; others that it should contain members elected by the general body of the profession. At last, by a compromise, the constitution of the Council was settled as it now existed. The Medical Act had been in operation nearly twenty years, and what had been done? If some were to be believed, it had done nothing for the profession. But could this be said of a Council which had had as presidents such men as Brodie, Green, Burrows, Paget, and Acland, and among its members such as Pennett, Hawkins, Quain,

Paget, Humphry, Syme, Turner, Thomson, Corrigan, Sharpey, Stokes, Parkes, Gull, Simon, etc.? If a Medical Board so constituted could not conduct the affairs of the profession, it would be better to have none at all. During the last twenty years, the ability and skill of practitioners of medicine had increased very greatly, and he could not allow that the condition was so bad as to demand the panacea of a conjoint scheme. No student could now enter on the study of the medical profession without having passed a preliminary examination before being registered as a student. The period of study had been extended to four years, and the examinations had been made much more extensive, there being in all cases two, sometimes three, and all being both written and oral; besides which, clinical examinations were now universal. The rejections at the examinations amounted now to thirty per cent. The Medical Council had also established visitation of examinations—at first conducted by members of Council alone, and afterwards by them in conjunction with other persons; and many defects which existed in the examinations had been remedied. One thing that showed the improvements that had been effected, was the returns supplied to the Council from the Medical Department of the Army. At first, the proportion of rejections was large, but now it was reduced to a minimum, as shown in the returns now before the Council, where, of sixty-one candidates, only two were returned as having been rejected. He would repel the insinuations made as to the low condition of the Scottish diplomas and degrees; if they were low, it was the fault of the General Medical Council. It was not the fact that diplomas in Scotland were placed at a low standard in order to attract candidates. The Medical Act had not been altogether inefficient; it had changed the character of the profession; and how had this been done? Not by stringent rules, but by moral suasion; by the issuing of recommendations which had been complied with by all the bodies with but few exceptions. In these circumstances, he did not think there was need of any great amount of legislation. The Duke of Richmond and Gordon had acted wisely in abstaining from a revolutionary measure. He had some sympathy with what Dr. Humphry had said about the independence of the licensing bodies; but he did not much object to submitting rules to the Privy Council. The Bill provided that candidates should be tested in all departments; and permitted partial combinations of examining bodies. The plan of combination had been tried in Scotland and acted extremely well. The combined boards there took the first examinations of other bodies *ad eundem*. In the Universities, the examinations were not conducted by the professors alone, but partly by other examiners. In England, an attempt was made to procure combination between the licensing bodies; but it failed, and nothing was done from 1859 to 1870, when the English bodies woke up furiously, and went in for a conjoint scheme, and tried to force Scotland and Ireland to adopt a plan of which they did not approve. There was not even yet a conjoint scheme in operation in England; it was considered as an experiment; and if conjoint boards were made compulsory by an Act of Parliament, there would be no way of getting out of the matter. The result of the working of the plan should first be ascertained. The *ban-dictum* would be one board for the three kingdoms; and what would it have to do? About 1,350 candidates would have to be examined each year; and this number must be multiplied by four to represent the number of examinations to be conducted. The twelve labours of Hercules would be a mere joke in comparison with the labour of such a board. It might be said that the board could be divided into sections; but what then became of uniformity? Again, the examiners would probably not be different from the present ones—the best that could be chosen. But it was proposed to form three boards; and how was this to ensure uniformity, especially if the boards were divided into sections? Again, in Scotland there was the difficulty that the examinations were held in various places; while, in England, very few qualifications were given elsewhere than in London. Another objection was, that in England the whole burden of regulating the examinations was thrown on a committee; the medical bodies had parted with the independent power of examining candidates who would be entitled to receive their diplomas. If the ancient bodies were to be maintained, they should be careful how they parted with their identity and autonomy and independence. The examining board was to be composed of the *representatives* of the universities and medical corporations. In consequence of the introduction of the universities, two results might arise; either the standard of the university degrees might be lowered, or the influence of the universities might cause the level of the licence to practise to be raised too high. Candidates who passed the examination and obtained their licences to practise would not care for the diplomas of this or that body. The university degrees should be given only after a more strict examination in every subject, and therefore the universities should remain separate from a conjoint scheme. Sir Robert Christison had

said that he could see nothing but evil from the adoption of a levelling system. He (Dr. Wood) trusted that the Council would pause before taking a leap in the dark.

"Facilis descensus Averno;  
Sed revocare gradum, superasque evadere ad auras,  
Hoc opus, hic labor est."

He approved of the present Bill as a mild measure, and would advise the Council not to interfere too much with existing machinery.

Sir DOMINIC CORRIGAN could not support Dr. Humphry's proposal. Dr. Wood's defence of the Scottish bodies was complete. While the English authorities had done nothing, the Scottish boards had carried out the principle of combination. He had long advocated double qualifications, but not conjoint schemes. He did not think that the Council would stultify itself if it did not reaffirm its former vote; but it would rather stultify itself by doing so. The obligation to pass the examination of the conjoint board would lower the standard of medical education. It was absurd that a minimum qualification should entitle to registration, while a high one, such as that of the University of London, should not have that privilege. The resolution also forestalled the opinion of the Council on the Bill. There was no such thing as a universal level in nature; men were not on the same level in the practice of medicine or elsewhere in society; and the attempt to procure uniformity of qualification was opposed to common sense.

Dr. ROLLESTON pointed out that, by the provisions of the conjoint scheme for England, the Universities retained power over their degrees. With regard to the difficulty of conducting the examinations, could not they be conducted in various local centres by means of printed papers sent by post? As to the statement that there was no need for legislation, it was necessary that something should be done, for the good of Government as well as of the public. By the formation of a conjoint board, good was done by securing a healthy rivalry within the board, and all the advantages to be got from centralisation were obtained. He advised the Council to adopt Dr. Humphry's proposal if they desired to escape further centralisation. If they did not approve the proposal, they would find that at some time a *Statute-examen* would be instituted.

The hour of six having arrived, the debate was adjourned on the proposal of Dr. Rolleston.

#### Thursday, April 11th.

Dr. ACLAND, President, took the Chair at 2 P.M.

*Conjoint Examining Boards.*—The adjourned debate on Dr. HUMPHRY's motion was resumed.

Dr. ROLLESTON said that it was better that the medical profession should take in hand the formation of conjoint boards than that Government should do it. That Government interference was likely, was shown by Lord Ripon's Bill in 1870, which would have been passed but for accidental circumstances. He had again read the arguments of Sir R. Christison against conjoint boards as brought in question in the address which he delivered at the meeting of the British Medical Association in Edinburgh, but they had made no impression on him. The State was likely to take in hand examination for licences to practise; and, indeed, had to some extent done this, with reference to soldiers and sailors. He could not admit the objections that it was not possible to examine a large number of candidates by a conjoint board. About 660 persons were registered each year. Would the University of London, for instance, think it a difficult matter to give 660 candidates an uniform examination?

Sir DOMINIC CORRIGAN objected to Dr. Rolleston being allowed to make a second speech.

The PRESIDENT ruled that Dr. Rolleston, having been interrupted in the course of his remarks on the previous day by the time for adjournment having arrived, was in order in now completing them.

Mr. TEALE said that, if Scotland stood alone, perhaps the views of the Scottish members might be accepted. But the Medical Act had extended the privileges of members of the profession in the various parts of the kingdom, and the question must be discussed in accordance with the general law. The present was a critical period in the history of the Medical Council. Registration was indeed necessary, and might be easily done; but could it be said that medical education was in a satisfactory state? No doubt there had been improvement; but there was a general feeling that the Council had not done so much to improve medical education as it ought. It would be very unsatisfactory if the Council were to go on simply making recommendations, which might not be carried into effect by the medical bodies for three, four, or five years. This took away much of the earnestness of the Council. What would be the object of giving increased power to the Council, if it were to be flattered away in super-

vision of the examinations held yearly by each of the nineteen examining bodies—in all, fifty-seven examinations? He shared in the disappointment generally expressed by the Colleges, by the British Medical Association, and the profession generally, that the Bill did not provide for securing a single conjoint examination. Dr. Wood had said that the establishment of a conjoint system would cause the standard of examination to fall to a low level; but it would be the duty of the Council to see that the standard neither fell too low nor rose too high. The latter condition was as much to be feared as the former. Nor would it lower the standard of the higher titles, as had been suggested. He agreed with Dr. Humphry, with regard to Oxford as well as to Cambridge, that it would be a great boon to be relieved from the necessity of examining students for a mere licence. If they were relieved from the duty of examining for the registrations, the Universities could raise the examinations so as to select the best class of candidates for their degrees. He was convinced that, unless there was some form of conjoint examinations, the days of the Medical Council would be numbered; it would be swept away and replaced by the State.

Dr. STORRAR said that the University of London would have no difficulty in examining a thousand students in a year. The College of Surgeons of England illustrated what could be done. He would support Dr. Humphry's motion. He thought that the Bill involved a principle on which it was necessary that the Council should express an opinion. He approved of the clauses in Lord Ripon's Bill of 1870 with regard to conjoint examinations, and also approved of Clause 15 of the present Bill. The University of London had referred the Bill to a Committee of medical and non-medical graduates. The report was not yet in such a state that he could make it public, but he might say that the Committee were unanimous; and no doubt the report would be adopted by the Senate. He had been much engaged in the conflict for medical reform before the passing of the Act of 1858. In 1856 or 1857, a medical reform bill was introduced into Parliament. Its main features were—registration, and the abolition of local jurisdiction; but it proposed also to give the medical corporations power to examine not only their own candidates, but also all University graduates. This was resisted by the Universities; and, after some discussion in the House of Commons, the Bill was referred to a select Committee. This Committee took no evidence, but approved of registration and the removal of local jurisdiction, and, to meet the anomaly of nineteen examining bodies carrying on a species of Dutch auction, proposed the establishment of examining boards for registration under a Medical Council. The Bill came back to Parliament; the Universities and corporations fought for their privileges; and the Bill was lost. In 1858, the then Home Secretary, Mr. Walpole, suggested a compromise. He omitted the central examining boards, but gave the Medical Council power of regulation and supervision. As the Bill advanced, an attempt was made in the House of Lords to encroach on the province of the corporations, but it was put aside. When the Bill at last became law, it had much of the appearance of a regiment that had come out of a general action. However, the Council made the best of it, and had for twenty years been endeavouring to carry out its principles. He concurred with Dr. Rolleston that, if the Medical Council did not move in the direction indicated in the Marquis of Ripon's Bill, the strong hand of the Government would interpose, and settle the matter; and public opinion on the subject was more advanced in 1878 than it was in 1858. He was surprised to hear it stated that the examining bodies in Scotland had availed themselves first of the section in the Act enabling them to combine. When the Bill passed, it was thought by some that the Scottish Universities were not entitled to give a qualification in surgery; and this produced in 1859 a proposal for a conjoint scheme. The question at last came before the Privy Council, and it was decided that the Universities had a right to give a surgical qualification. And then the Medical Council, new to its work, when the proposal for combination came from the Scottish Colleges, omitted to make a condition that the single examination should be abolished—and thus, in fact, added two examinations to those already existing. The Scotch plan was not the Council's conception of a conjoint scheme; no doubt it was a very advantageous arrangement, but to give the Scottish corporations much credit for it was absurd. He did not agree with Dr. Wood's estimate of the present condition of examination. To say that there had been no improvement would be wrong; but he must deny that the present condition was so satisfactory that it could not be improved. He must now enter on more delicate ground. Dr. Wood seemed to imply that the examinations were so good in Scotland that it was not desirable to interfere. But, while he had much sympathy with Scotland, he could not be blind to its defects. He could not concur with Dr. Wood's conclusions. The proposal to form a conjoint board was a form of

declaration that the present system was imperfect. The English bodies did not desire to impose on Scotland what they did not wish for themselves, and had begun by forming a conjoint board in England. As regarded the University of London, if it had confined itself to its own narrow interests and its special duties, it had no need to go outside its charter; but the Senate had been led to take a more expanded view and to consider what was required for the profession and also for the public; and they felt it to be a duty to assist in establishing conjoint examinations for the common good. But the University would resist such an overriding of its powers as was contemplated in the Bill.

Dr. HALDANE said that the idea of a conjoint scheme was no doubt very seductive. Six or seven years ago an attempt to bring one into operation was commenced, but as yet the success was not great. Even in England it had not yet been tested by experience. In Scotland, an attempt was made to establish a conjoint scheme, and various meetings were held; but the negotiations ended in nothing. It was impossible to form a board in which the Universities and corporations should be on the same level. If it was difficult to form a board in England, it was much more so in Scotland. In England, about 14 per cent. of the persons placed on the *Medical Register* in a year held University degrees; in Scotland, the numbers were almost equally divided between the Universities and the corporations. A successful attempt was made in 1859 by the combination of the examinations of the Royal College of Physicians of Edinburgh with those of the Royal College of Surgeons of Edinburgh, and with those of the Faculty of Physicians and Surgeons of Glasgow. By this plan, a candidate after undergoing a single examination could obtain a double diploma. The board consisted of an equal number of examiners from each College; the College of Surgeons took entire charge of the examination in surgery, and the College of Physicians of that in medicine; the remaining subjects being each allotted to examiners from both Colleges. This plan had greatly diminished the number of single qualifications. It was true that many did still take the single qualification of the Edinburgh College of Physicians, but they were in general already members of the Royal College of Surgeons of England. Very few Edinburgh students applied for the single qualification. It was not desirable that the Universities and corporations should be amalgamated. The degrees of the Universities should be much higher than the licences of the corporations. It would be unfortunate if the University degrees should be looked on as mere licences to practise; but by the passing of the Medical Act they had been placed on the same level with the diplomas of the corporations. There was a difference between Scotland and England, inasmuch as the English Universities were not great centres of medical teaching—perhaps their retired position, which gave them greater advantages for literary study, interfered with this. But in Scotland the condition was quite different. The University of Edinburgh was the great centre of medical teaching in that city; and the same was the case, with some modifications, in Aberdeen and Glasgow; and the value of the teaching in the Universities was fully proved by the large number of students who resorted to them. Then as to the examinations, the reports of the visitors, and the returns from the army board, must be accepted as satisfactory evidence of their efficiency. He did not see how a conjoint scheme could raise the character of the examinations; the examiners would be the same men as at present. He thought it would be a pity to make a change when all things were going on well, and the Council had done much good. Dr. Rolleston had threatened the Council with a *Staats-examen*. He would prefer it to a conjoint board. Let all the examining boards go on as at present under the supervision of the Council, and let each candidate undergo, before being registered, a *Staats-examen* a year after having the ordinary examination—the intervening year being spent in holding hospital appointments, or as an assistant, or in travelling. He believed that such a plan would be more satisfactory than a conjoint board, and would keep up the character of the examination of the various bodies.

Dr. QUAIN had taken a considerable part in the formation of the conjoint scheme for England; and he believed that its objects were not quite understood. Before 1858, there were many scattered examining bodies giving unequal qualifications. The College of Surgeons of England, for instance, gave a qualification in surgery which required no previous training; and in Scotland some of the bodies gave degrees to persons whom they had scarcely seen. By the Act of 1858, all the bodies were put on an equal footing. Mr. Walpole expected that they would avail themselves of the power given them to combine, in order to give a double qualification. In Scotland, certain bodies combined to give qualifications in medicine and surgery; but they also gave their diplomas separately. With reciprocity of right to practise there should be also uniformity of qualification; but this had not yet been attained. In the letter addressed to the Council in 1870 by Mr. Simon, on behalf

of the Lord President of the Council, the following sentences occurred:—"The Lord President doubts whether the present system, under any practicable kind of supervision, can either work satisfactorily for medical education, or can provide adequate and uniform security for those great public interests which are concerned in the efficiency of the medical profession." That was the declaration of the Government, and it was, no doubt, the intention of the Lord President (the Marquis of Ripon) to act in some way. And there was also the opinion of the profession at large, as expressed in the memorial signed by nine thousand members of the Medical Reform Union, and presented to the Council by Dr. Bell Fletcher, that "the present system of granting licences to practise distracts students, fails to protect the honour of the profession, and is opposed to scientific unity and the best interests of the public". The Council had to choose between the provisions of Lord Ripon's Bill and those of the present Bill. As regarded Dr. Haldane's proposal, what object could be gained by having a second examination? It must be remembered that the Council worked not for the profit of the colleges and universities, but for the public good. Its choice lay between the formation of conjoint boards and what was proposed in the Duke of Richmond's Bill. The formation of conjoint boards was much more easy than some members of the Council thought. The College of Surgeons of England and the University of London had difficulties to contend with, but they overcame them and joined in the formation of a conjoint board for the public good. The English medical authorities had agreed to put their examinations together, and to offer a course of education and examination which would satisfy everybody. After passing the examinations of the conjoint board, candidates would be entitled to receive the diplomas of the corporations; from the universities they would get nothing. If the Council went on discussing the privileges of this or that medical body rather than consulting for the public interest, it would sooner or later be superseded.

Mr. TURNER objected to the discussion of an abstract resolution. It was not treating the Duke of Richmond with courtesy. He thought that the Council should at once proceed to the discussion of the Bill. In his opinion, the motion was an attempt to commit the Council to an abstract proposition before discussing the Bill. He had a great mistrust of abstract propositions; they were often like snakes in the grass, and traps to catch the unwary. He thought that Dr. Humphry's resolution demanded more explanation. Dr. Humphry had left some chapters out of his narrative. Some points in the minutes of the Council did not tell so strongly in favour of conjoint boards as had been represented. The resolution of February 1870 was said to have been carried by a majority of all the divisions of the kingdom. This was true only to a certain extent. On that occasion, various motions and amendments were brought forward; and, when the resolution which was adopted was passed, four members declined to vote, of whom two were Scotch, one Irish, and one English. None of them could be called supporters of the resolution; moreover, Sir Robert Christison, whose opinion on the subject was well known, was absent. Some years ago, a protest against a conjoint scheme, signed by eminent practitioners, was sent to the Council from Scotland. The movement in favour of a conjoint examining board was not national. It had been said, in support of the establishment of conjoint boards, that the present system was an anomaly, and that a conjoint scheme would ensure uniformity. If a plan of medical examinations were now being formed for the first time, no one would think of constituting nineteen separate bodies; but the Council must look at the subject in its historical aspects. Many of the examining bodies were of great antiquity, and had shown themselves earnest in promoting the improvement of the medical profession. He did not see why the Council should step in and stop their progress. They had also shown themselves ready for reform when required; why, then, should their privileges be taken away, unless they acted improperly? It had been said that the examinations of some of the Scottish boards were not up to the mark; but against this statement he would place the reports of the visitors on examinations. The Council had already sufficient power, under the Medical Act, in regard to the examinations; and the argument as to anomaly was of no value. As to uniformity of standard of examinations, was it desirable to have an uniform standard, and, if it were desirable, could it be obtained? It was a phantom which might be chased in vain over Irish bogs, or Scotch moors, or London streets. A standard of examination was a mental process, and varied not only with different persons, but at different times in the same examiner, according, e.g., to the state of his digestion. Again, a candidate's knowledge could not be weighed or measured out like tea or beer: it was a variable quantity. It had been said that, with a conjoint board in each division of the kingdom, there would be an approach to uniformity. There might be some approximation if there were one board

for the United Kingdom; but separate boards would have their own standards. To procure uniformity, all the candidates must be examined by one examiner in each subject. As regarded the conjoint scheme for England, the English authorities were introducing a series of examining boards into the scheme, thus leaving matters just where they were. Another difficulty was that, under the conjoint scheme, a great system of centralisation of examination would be introduced. He was glad to hear Dr. Rolleston protest against centralisation, and had hoped to hear him go on to argue against the conjoint scheme. One of the results of the formation of a central examining board would be the aggregation in the locality of a number of persons professing to prepare students for examination. A central board would be a great encouragement to cramming, and would interfere greatly with medical study. He referred here to the reports on the Universities of Scotland recently presented by a Royal Commission, consisting of eminent and unprejudiced men not connected with these institutions. They said that the growing tendency to increase the number of examinations was to be deprecated. It would be a misfortune if the requirements individually of the Scottish Universities were impaired, and if they were made subservient to the requirements of a central examining authority. The report spoke also of the evil influence of examination on education. Nothing further was needed to show the evil of submitting great bodies to the control of central boards. It might be said that university students would have to pass a subsequent examination before obtaining their degrees. In the English scheme, the university students must pass the examination of the conjoint board before that for the degree; and thus a new examination would be introduced which might withdraw attention from the subjects of the higher examination. Under the conjoint scheme, the same examiners would be appointed as now performed that duty, and the examinations would be practically the same. It was an argument against conjoint boards that all the candidates in each division of the kingdom would have to come before the same examiners; and it was not to be expected that men engaged in the duties of an active practice could give the time necessary for conducting the examinations, and hence these would fall into the hands of less well qualified men. The proposal to send the questions and answers by post might do very well if the examinations were entirely written; but they were also oral and clinical—and patients and candidates could not be sent by post. The telephone, indeed, enabled persons to communicate at long distances; but it had not yet reached such perfection as to enable, for instance, an examiner in Edinburgh to examine a candidate in Aberdeen. The candidate must go to the examiner, or the examiner to the candidate. If the latter, then the already great demands on the time of the examiners in Scotland would be increased. It was proposed to make the establishment of examining boards compulsory; but compulsion was not the spirit of modern legislation, which sought rather to persuade, and to remove difficulties in the way of carrying out plans of improvement. This was done by the Duke of Richmond's Bill. He objected to Dr. Humphry's proposal on national grounds. There were also certain local objections. The Scottish Universities were great teaching institutions, and had a great interest in the question, there being at present about two thousand medical students in Scotland. On the other hand, the Universities of England did not contain more than about fifty students. Again, the Scottish Universities, and the Queen's University in Ireland and the University of Dublin, carried out a complete examination in medicine and surgery, and the Irish Universities in midwifery also. The examination for degrees was in every sense thorough, and the provisions and appliances for teaching were the best that could be obtained. The fact that the Scottish Universities were frequented by students from all parts of the world, was evidence of the high estimation in which their teaching was held. These Universities objected to having their students compelled to go through the minimum examination of a conjoint board. The Council had no right to seek to impose an additional examination on the university students, and to expect them to pay such a fee as might be required for a conjoint examination. There was another and a more serious matter. Under the present system of diversity of examination, inducements were held out to candidates to proceed to higher qualifications; but, if men were allowed to be put on the *Register* with a minimum examination, many would be content with this. A compulsory system would in this way produce great injury by inducing students to stop short in their progress. The Scottish Universities would send out a smaller number of graduates, and would undergo deterioration in the estimation of the profession. The Scottish Universities differed from the other Universities in being poor, and in not being able to draw on the public purse for the payment of examiners, as the University of London could do. The Irish Universities also were more fortunate in this respect than those in Scotland. The examination fees were an important

source of income to the Scottish Universities; in Edinburgh, last year, they amounted to £3,000. These fees did not go to the examiners, but were paid into the university treasury; £300 being paid to examiners, and £350 to the non-professorial examiners. The remainder was applied to general university purposes; and thus the next generation of students actually received back, in improved means of teaching, that which their predecessors had paid. It would then be necessary to take care that this income of the Universities was not reduced by legislation. Under the proposed plan of conjoint examining boards, there would be a loss in consequence of the falling off of fees.

Dr. AQUILLA SMITH heard nothing which could induce him to change his opinion against the conjoint scheme, but much to confirm it. He was much indebted to Mr. Turner for his lucid exposition. He agreed with Mr. Turner that the Council was not treating the Duke of Richmond with proper consideration in taking up Dr. Humphry's resolution before considering the Bill. He believed that the formation of conjoint boards would discourage men from going on to the higher qualifications. He had observed with satisfaction that in recent years there had been an increase in the number of graduates in the University of Dublin; but, under the conjoint scheme, as soon as men got into general practice, all their aspirations for higher degrees would be laid aside. He agreed that it was injurious to amalgamate the universities and corporations in conjoint schemes. It was derogatory to the universities to condescend to such amalgamation; their examinations should be of a high standard.

Mr. MACNAMARA said that the question for discussion was, whether the Council would accept the principle of conjoint boards, or the Lord President's Bill. If Dr. Humphry's resolution were passed, it would deprive the Bill of its backbone. Conjoint schemes had a tendency to lower medical education. If candidates were required to undergo the examination of a medical and of a surgical board separately, they could not obtain their qualifications if they were weak in either subject. He would now make the *amende honorable* to the Scottish bodies for what he had previously said, and would now say that disparity of examination no longer existed among them. He had made very careful inquiries as to the manner in which the examinations were conducted in Edinburgh and Glasgow, and had found that they were all that could be desired. When he was a grinder, he used to charge thirty guineas for preparation for Irish examinations, twenty for English, and ten for Scotch; but now he found that the fees were alike in all cases. The Bill provided for the consolidation of licences; it permitted and encouraged the formation of conjoint boards. This was much better than compulsion. If the English bodies saw their way to the formation of a conjoint board, let them form one; but they should not force their views on the Scotch and Irish. He thought that the Council should take up the Lord President's Bill and go through it clause by clause; otherwise, if the Council succeeded in subverting the principle of the Bill, they would only stop legislation for the present year, and would expose themselves to the risk of being afterwards obliged to accept a stronger measure.

Sir WILLIAM GULL said that the difficulties in the way of conjoint schemes might be surmounted. Mr. Turner had said that a conjoint scheme was impossible in Scotland, and the real reason came out at last—it was a pecuniary one. The Scottish universities depended on the fees paid by the candidates for graduation, and the fear was that those ancient and historical institutions would dwindle away for want of funds. At least eight-tenths of all the arguments brought forward were outside the question. If he understood the principles of the conjoint scheme, the establishment of a minimum examination would be in favour of higher education; it would leave all the bodies free to raise the standard of education for their higher degrees and diplomas. The Scottish bodies were teaching down to a minimum (Mr. TURNER dissented). If not, how was it that there were so few university graduates in London, and so many in Scotland? If the Scottish Universities examined according to a maximum standard, they could not fail to have few graduates. The question was partly political and partly monetary, and involved many interests which no government could overlook. The Bill would have been much more stringent if it had not been for politics. Dr. Andrew Wood had said that the question must be looked on from three aspects—*respite, aspic, prospect*—and that if the Council did not let matters go on as they were, they would be going to Hades. He saw no ground for this. The Council could but regulate medical qualifications, unless it could supervise examinations; but this could not be done under the present system. Unless conjoint boards were formed, the Council could not do its duty. The Council should strengthen the hands of the Government, and enable it to overcome the political difficulty, and to act for the good of the profession and the public. He did not agree with the opinion that men who passed the minimum examinations would not go on to the higher diplomas; he thought that many

would not stop at the minimum qualification, but would go beyond it. Mr. Macnamara had said that the adoption of Dr. Humphry's motion would prejudice the passing of the Bill. He hoped that it would do so. He did not think that the difficulties in the way of forming conjoint schemes were insuperable, though they might be great. That the principle was a desirable one, no one could doubt. It would be certainly much more easy to supervise the examination of three boards than those of nineteen. In voting, the Council should consider what was for the general good.

Dr. PITMAN supported the motion. It had been stated by some that they approved of conjoint schemes, but at the same time they doubted whether they could be carried out. The combination of the Scottish colleges in 1859 was not a conjoint scheme, according to the view held by the English boards. Besides the combined examinations, the Scottish colleges reserved the right of granting single qualifications. What security was there that the examinations were a fair test of knowledge, if the present plan were allowed to go on? Unless constant supervision were exercised, it would be impossible to secure their efficiency. Mr. Turner had objected to the statement that the minimum examinations in the Scottish Universities did not differ from those of the corporate bodies.

Mr. TURNER said that the Universities required four years of study at a medical school; the corporations required only three years at a medical school, another year being spent elsewhere.

Dr. PITMAN could not see that it was an advantage to require the four years to be spent entirely at a medical school. He did not think that the preliminary examinations were any better in the universities. It was also not desirable that examining bodies should be also educating bodies. No doubt the system in Scotland had been much improved, but it was capable of still more improvement. What was wanted was uniformity of examination by a single board. The difficulties in the way of forming a conjoint scheme had been overcome in England; in Scotland there had been a failure, through want of perseverance. Twenty years of permission to combine had not brought forth much, and it was now proposed in the Bill to continue the permissive system. He trusted, however, that Scotland and Ireland would follow the example of England, and form conjoint boards. The day would come when the universities and corporate bodies would have to combine or be superseded; and it would be better to act voluntarily than under compulsion. The vote of the Council, he thought, would have little influence unless there were a fair majority in favour of Dr. Humphry's resolution. The question was one which concerned the public as much as the profession, and the public would act for themselves.

On the motion of Mr. SIMON, the debate was again adjourned.

*Returns from the Army Medical Department.*—It was moved by Dr. ANDREW WOOD, seconded by Dr. AQUILLA SMITH, and agreed to: "That the returns from the Army Medical Department be inserted in the Minutes, and that the best thanks of the Council be given to the Director-General of the Army Medical Department for his courtesy in sending these returns."

The following is an abstract of the returns.

	Aug. 13, 1877.	Feb. 14, 1878.
Total number of candidates ... ..	37	24
Found physically unfit ... ..	3	4
Failed to appear at the examination ... ..	3	1

*The British Medical Association and the Medical Acts Amendment Bill.*—The following letter from the Chairman of the Medical Reform Committee of the British Medical Association was read.

Chester, April 9th, 1878.

"Dear Sir,—I thank you for acknowledging the receipt of my communication respecting the amendment of the Medical Acts. On behalf of my Committee acting for the British Medical Association, I have to express a hope that the opinion of the General Medical Council may be taken on the subject of the distinct representation of the profession upon it. The action of the Association since 1866, when a deputation on its behalf waited on the Council, proves that the Association is in earnest in its desire to obtain [it].

(Signed) "EDWARD WATERS,

"Chairman of the Medical Reform Committee.

"Professor Acland, M.D."

Mr. TURNER asked the President if he could inform the Council whether the Medical Acts Amendment Bill referred to in the letter from Dr. Waters (read on the previous day) as approved and promoted by the British Medical Association, had been approved and promoted by the general body of the members of the Association, or only by the Medical Reform Committee of that Association.

The PRESIDENT answered that no information had been received by him on the subject referred to in the letters of Dr. Waters, other than was contained in the communications laid before the Council this day and yesterday.

Friday, April 12th.

Dr. ACLAND, President, took the Chair at 2 p.m.

*The Conjoint Scheme for England.*—Sir DOMINIC CORRIGAN, in asking the President a question concerning the Conjoint Scheme in England, stated that it would be desirable to have the latest information as to the present state of the conjoint scheme in England, and that with this view the President be requested to furnish the Council, if in his power, with such information.

The PRESIDENT stated that he had communicated with the Chairman of the Committee of Reference appointed under the medical authorities of England, on the subject of Sir Dominic Corrigan's question. The Chairman of the Committee, Sir James Paget, was in a position to give an answer which would be satisfactory to the Council.

Sir JAMES PAGET said that, shortly after the conjoint scheme proposed by the English Medical Authorities received the sanction of the General Medical Council, the authorities appointed a Committee of Reference, by whom regulations had been framed for the education and examination of candidates for qualifications for registration. The regulations were now complete, and the copy of them which he had in his hand might be published, but that they required the sanction of the authorities. This sanction, he had no doubt, would be granted, and the scheme could be brought into operation at the commencement of the next winter session in October. But whether it ever would come into operation might depend on the decision at which the Council would arrive to-day. He was not prepared to say what would be the decision of the College of Surgeons if the institution of conjoint examinations in all divisions of the kingdom were not made compulsory; but the College of Physicians, in the document just printed in the minutes of the Council, had said that in that event the "Bill would compel them to abandon the scheme and all hope of reaping any fruit from their labours" in its construction and in the preparation of the rules of education and examination.

*Conjoint Examining Boards.*—The adjourned discussion on the resolution proposed by Dr. HUMPHRY was resumed.

Mr. SIMON had given much attention to the discussion; and would first refer to the objections against the principle of conjoint boards. It had been said that the introduction of the resolution forestalled the discussion of the Bill on its merits. Mr. Turner had said that the resolution was abstract and obscure (no doubt, Dr. Humphry could explain it); that it was a trap for the unwary, a snake in the grass, etc. And Dr. Andrew Wood had told the Council that they would be going to the *facilis descensus Averno* if they adopted the resolution; but they must have felt relieved on hearing that the translation meant that the Scottish universities were likely to lose money if a conjoint scheme were adopted. It had been said also (by Mr. Macnamara) that the passing of the resolution would take away the backbone of the Bill. But his complaint was that the Bill had no backbone; it was a mollusc, not to say a jelly-fish. Sir William Gull had said—no doubt for reasons satisfactory to himself—that political influences had made the Bill such as it was; but the mere statement that such influences had been in operation made it all the more important that the Council should put forward a strong opinion in support of the principle of conjoint boards. Mr. Turner said that the object of legislation was to persuade people to do what was right. That was the duty of the preacher: the function of legislation was to command, and, in proper cases, to enforce obedience by penalties. He believed that, from early times, permissive legislation had been held to be in itself wrong, or to have as its object the remedy of some wrong already existing in a restrictive law. The object of the Medical Act and of the Council was to provide guarantees that none but properly qualified persons should be legally entitled to practise, and that the standard of medical education should be as high as circumstances permitted. Could such guarantee be given under the present circumstances of competing examining boards? Certainly not. This answer was not aimed at this or that examining board, but was intended to apply to the whole kingdom; and every man not influenced by local considerations would adopt it. The present system did not give adequate guarantee. What tendency could it have, except to favour the candidate who paid, against the public who did not pay? An appeal might also be made to facts. Granting that there had been considerable improvements in the examinations, many of these had taken place in consequence of pressure, and there was no guarantee for their continuance if the pressure should be withdrawn. It would be a great relief of the diffi-

culties under which the Council laboured if it could have power to enforce its recommendations. The Council could not exercise full power over the examinations: it could only visit them thoroughly in the course of ten or more years; and could this be effective in restraining downward competition? The idea of uniformity of standard had been objected to as being impossible; and it had been said that the endeavour to obtain it was like pursuing a phantom. It was also said that it was not desirable; that it would tend to mediocrity, and to sending into the profession a large number of superficially educated men. An objection had also been raised on the ground of the expenses incurred by the candidates in travelling to the places where the examinations would be held. But what of the expenses incurred at present by English students in travelling to Edinburgh? But the greatest objection urged by Mr. Turner was the effect which a conjoint scheme would have on the finances of the Scottish universities. These were great medical schools; and Edinburgh received £3,000 last year from fees, which went to maintain the school. But what if the same principle were applied elsewhere—if, for instance, the medical school of St. Bartholomew's Hospital were to have the privilege of conferring degrees and were to receive the benefit of the fees in the same way? The question must not be decided on as a matter of local interest, but of principle; as a matter of general application. The cases of the English and Scottish universities were not strictly comparable; they would be more so, if each of the separate colleges of Oxford and Cambridge had the power of granting degrees. He knew that the Scottish universities had the privileges of old; but the question was one of right and wrong, and not to be met by the reply "*Beati possidentes*". Was it not the fact that some medical practitioners in England obtained degrees from Scotland, for the purpose of making the public believe that they held qualifications superior to those of the English corporate bodies? He agreed with Mr. Teale that it was to be regretted that university degrees were made qualifications for registration. He did not, however, think that the universities should take no part in conjoint examining boards; the universities and corporations might combine, and still retain their functions with regard to the higher qualifications. When the public paid members of the profession their fees, it was expected that the coin should be of sterling quality; and so, in return, practitioners of standard quality should be secured for the public. That was the principle at which the resolution aimed—to establish a qualification that could not fall below a certain standard, and that could be improved from time to time. He hoped that the advantage of having but one legal title, as proposed in Lord Ripon's Bill, would be recognised; and that the resolution would be adopted by the Council.

Sir JAMES PAGET said that the Bill no doubt contained clauses that required change, but there was also much in it which was for the advantage of the profession as regarded conjoint examination. The Bill proposed two plans; a double qualification, and the formation of rules for ensuring uniformity. The Council hoped and looked for uniformity in the minimum qualification. If there were to be an equal right of registration, the qualification must be as uniform as possible. He believed that there was a general understanding that, in most if not all of the medical institutions, unworthy candidates still passed. The Universities complained of being obliged to admit men to their degrees, because, although the result of the examination did not come up to the standard for degrees, they would not say that they were unfit to practise. If the Council would not have conjoint examining boards, the public would take care that there should be some uniform standard below which none could be admitted to registration. The majority of the Council, the British Medical Association, and the examining bodies, had declared in favour of conjoint boards. The English conjoint scheme was nearly ready for operation, but it was now in greater peril than at any former period. Unless conjoint boards were established in all the divisions of the kingdom, there would be the alternative, according to the Bill, of the plan of double qualifications, which would virtually disfranchise three-fourths of the bodies granting single qualifications as effectually as a conjoint scheme would do. The difference would be that, as the plan was carried out in England, the bodies exercised the authority by their own will and their own rule; and this was preferable to being subjected to rules framed by the Medical Council and approved by the Privy Council, as proposed in the Bill. Suppose that there were a state examination. There were two ways of carrying out this. One was according to Dr. Haldane's proposal, by which every candidate for registration would have to undergo an examination a year after obtaining his diploma. But such a system would indicate that the degree of doctor of medicine, the diplomas of the Colleges, were not fit tests of qualification to practise. The degrees and diplomas, then, now held in honour, would be reduced to great dishonour. It might be said that the army and navy re-examined

candidates. These examinations, however, were in the first place adopted for the purpose of selecting candidates by competition, though they had of late apparently lost that character in consequence of the dearth of candidates. Another method of carrying out a State examination was to make it precede the granting of diplomas. That was the scheme of Lord Ripon's Bill. There was much to be said for such a scheme; but it must be contrasted with the conjoint scheme, under which the candidates on passing would be entitled to receive from the corporate bodies diplomas which would be registered. In the one case, the passing the examination would take a man straight to the *Register*; in the other, he would have the right to the registrable diplomas of the corporate bodies. With the exception of the Crown nominees, the members of the Council were the representatives of bodies having certain legal rights. But, if the principle of State examination were admitted, what would be the position of the Council? He saw nothing but calamity from falling under the Bill in an unaltered condition, or under a system of State examinations. The medical authorities had done great things for medical education; and on them must depend the further improvement of education. It would have nothing done which might impair their position.

Dr. FERGUS could find nothing in the Bill to prevent the formation of conjoint schemes; it was permissive. Let the English authorities carry out their scheme, and show the other divisions of the kingdom how it worked. He thought that the Bill itself should have been discussed.

Dr. HUDSON said that he would vote for the resolution.

The PRESIDENT expressed his intention of voting in favour of Dr. Humphry's resolution. Having paid much attention to the admirable and temperate discussion which had taken place, he wished to affirm his conviction that the present system, under which nineteen different bodies had the power of admission to the *Register*, was not conducive to the interests of medical education in the kingdom. If the Council lost its present opportunity, results might happen, the nature and extent of which they did not know.

Dr. HUMPHRY replied to the objections to his resolution. In conclusion, he said that its object was that the medical authorities in each division of the kingdom should frame such a scheme as might best suit their special circumstances. Let the Scottish authorities frame such a scheme as would be best for Scotland, and let the Irish authorities do the same for Ireland. Let them use their liberty while they had it, and avoid falling into the hands of the Privy Council. The choice offered was that between compulsory and voluntary action.

The resolution was then put to the vote. The numbers were—for, 14; against, 10. The motion was declared carried.

Dr. ANDREW WOOD required that the names and numbers of those who voted for and against the motion be taken down.

*Majority, 14.*—The President, Dr. Pitman, Sir James Paget, Mr. Bradford, Dr. Rolleston, Dr. Humphry, Dr. Pyle, Dr. Storrar, Dr. Leet, Dr. Quain, Sir William Gull, Mr. Simon, Mr. Teale, Dr. Hudson.

*Minority, 10.*—Dr. Haldane, Dr. Andrew Wood, Dr. Scott Orr, Mr. Turner, Dr. Pettigrew, Dr. Aquilla Smith, Mr. Macnamara, Dr. Apjohn, Sir Dominic Corrigan, Dr. Fergus.

*The Powers and Duties of the Medical Council.*—Dr. PITMAN moved:

"That the duties of the Medical Council in relation to the various medical authorities (whether in separate or in joint action), should not be extended to the initiation of the examination-rules under which qualifications are to be granted, but should remain restricted, as now, to duties of superintendence and control, with power of making representation to the Privy Council in cases of default."

The resolution contained a principle adverse to clause 14 of the Bill, which recognised the existence of certain duties and powers in the Council, and further proceeded to impose additional duties without giving the necessary increase of power. It was proposed that the Council should frame examination-rules; but if it undertook to frame regulations for all the bodies, how would it find time for this? Those only who had been engaged on the Committee of Reference for the English conjoint scheme could form an idea. But even if the Council could undertake the duty, was it desirable that they should do so? He believed that the universities would not agree to having the regulations for their degrees laid down by the Medical Council. Then as to the corporations, he doubted whether the Council would be more competent to lay down rules for the guidance of these bodies than the authorities of the colleges themselves. What object was there in removing the power of making regulations from those who now possessed it? It would be like giving minute and restrictive instructions for the manufacture of an article, and then requiring the maker to put his name on it as if it were his genuine work. He had been struck

with the resemblance of the clause to certain resolutions passed by the Branch Councils in Scotland and Ireland. The clause provided a right of appeal to the medical authorities against the Medical Council; this was not a very dignified position for the Council. The clause certainly required amendment.

Dr. ROLLESTON seconded the motion, which, after some remarks in support from Dr. Andrew Wood, Sir D. Corrigan, and Sir W. Gall, was carried. It was subsequently amended by the insertion of the words "in general" between "should" and "remain restricted".

*The Medical Acts Amendment Bill.*—It was moved by Mr. SIMON and seconded by Dr. ANDREW WOOD, and agreed to:

"That the Council now resolve itself into a Committee of the whole Council, for the purpose of considering the Clauses of the Medical Act (1858) Amendment Bill."

Dr. ANDREW WOOD moved, Sir JAMES PAGET seconded, and it was resolved: "That Clauses 1 and 2 of the Bill be approved."

Dr. ANDREW WOOD moved, and Mr. TURNER seconded, "That Clause 3 be approved."

Mr. SIMON moved, as an amendment, and Dr. HUMPHRY seconded:

"That the Council so far approves of the intention of Clause 3 as to be of opinion that none but persons whose qualifications have been tested in medicine, in surgery, and in midwifery should in future be admitted to the medical register; but that, as regards the manner in which effect should be given to this intention, the Council refers to its previous votes on the subjects of conjoint boards and examination rules." The amendment was carried.

Dr. ANDREW WOOD required that the names and numbers of those who voted for and against the amendment be taken down.

*Majority, 13.*—Dr. Pittman, Sir James Paget, Mr. Bradford, Dr. Rolleston, Dr. Humphry, Dr. Pyle, Dr. Storrar, Dr. Leet, Dr. Quain, Sir William Gull, Mr. Simon, Mr. Teale, Dr. Hudson.

*Minority, 10.*—Dr. Haldane, Dr. Andrew Wood, Dr. Scott Orr, Mr. Turner, Dr. Pettigrew, Dr. Aquilla Smith, Mr. Macnamara, Dr. Apjohn, Sir Dominic Corrigan, Dr. Fergus. The amendment having been put as a substantive motion, was carried.

*The Obstetrical Society and the Education of Midwives.*—A letter was read from Dr. West, President of the Obstetrical Society of London, accompanied by copies of the amended regulations proposed by the society for the examination and registration of midwives. Dr. West also called attention to some points in the Medical Acts Amendment Bill, which, he thought, required amendment, and suggested that the Obstetrical Society might be allowed an opportunity of explaining that scheme to the Medical Council.

It was moved by Sir JAMES PAGET, seconded by Dr. ANDREW WOOD, and, after a brief discussion, resolved—

"That the request of the Obstetrical Society be complied with, and that they be informed that the Council has agreed to admit them to an interview on Tuesday at 2 o'clock P.M."

*Returns from the Licensing Bodies.*—It was moved by Dr. ANDREW WOOD, seconded by Dr. AQUILLA SMITH, and agreed to:

"That the annexed table, showing the results of professional examinations for degrees, diplomas, and licences granted in 1877 by the bodies named in Schedule [A] of the Medical Act, be received and inserted in the minutes."

The following is a summary of the table [I=First Examination; II=Final Examination; P=passed; R=rejected].

*Royal College of Physicians of London.*—Licence: I, R 8, P 7; II, R 19, P 97. Membership: I, R 1; II, R 3, P 23.

*Royal College of Surgeons of England.*—Membership: I, R 250, P 521; II, R 133, P 413. Fellowship: I, R 41, P 48; II, R 9, P 26.

*Society of Apothecaries of London.*—I, R 75, P 161; II, R 44, P 217.

*University of Oxford.*—M.B.: I, R 3, P 8; II, P 8. M.D. (Essay): P 1.

*University of Cambridge.*—M.B.: First Examination, R 18, P 32; Second, R 2, P 24; Third, R 2, P 11.† M.D.: II, P 4. M.C.: P 3.

*University of Durham.*—M.B.: First Examination, R 4, P 10; Second, P 2; Third, P 2. M.D. (Essay): R 1. M.D. (for Practitioners of fifteen years' standing): P 2.

*University of London.*—M.B.: Preliminary Scientific, R 76, P 60; First M.B., R 46, P 55;† Second M.B., R 10, P 22. M.D.: R 7, P 8. B.S.: R 3, P 3. M.S.: P 1.

\* In addition, one withdrew during the examination.

† The third is not, strictly speaking, the final examination, because every candidate has, subsequently to the third examination, to write a thesis and keep an "Act" in which he is subjected to more or less of oral examination.

‡ Of these, ten were among the candidates who proposed to go through the examination with the exclusion of physiology, and two were among those who, having previously passed the examination with the exclusion of physiology, presented themselves to be examined in physiology only.

§ Of these, five availed themselves of the option of reserving their examination in physiology for a future year, and seven who had previously exercised the same option passed in physiology only.

*Royal College of Physicians of Edinburgh.*—Science: I, R 3, P 10; II, R 26, P 115.

*Royal College of Surgeons of Edinburgh.*—Science: I, R 8, P 13; II, R 6, P 56.

*Faculty of Physicians and Surgeons of Glasgow.*—Science: I, R 22, P 7; II, R 10, P 21.

*Royal Colleges of Physicians and Surgeons of Edinburgh.*—Licence in Medicine and Surgery: I, R 52, P 101; II, R 68, P 102.

*Royal College of Physicians of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.*—Licence in Medicine and Surgery: I, R 4, P 8; II, R 4, P 13.

*University of Edinburgh.*—M.B. and M.C.: First Examination, R 83, P 175; Second, R 59, P 136; Third, R 14, P 108.\* M.D. (Thesis): R 2, P 34.

*University of Aberdeen.*—M.D. (By promotion): P 31. M.B. and M.C.: First Examination, R 37, P 59; Second, R 30, P 39; Third, R 13, P 41.†

*University of Glasgow.*—M.B. and M.C.: First Examination, R 68, P 72; Second, R 39, P 56; Third, R 15, P 63.‡ M.D.: I, P 1; II, R 2, P 2. M.D. (Thesis): R 3, P 15.

*University of St. Andrews.*—M.B. and M.C.: I, R 1; II, P 1. M.D.: R 3, P 10.

*King and Queen's College of Physicians in Ireland.*—Licence in Medicine: I, R 2, P 6; II, R 21, P 85. Licence in Midwifery: R 2, P 89.

*Royal College of Surgeons in Ireland.*—Licence: First Examination, R 56, P 109; Second, R 34, P 99; Third, R 34, P 99. Licence in Midwifery: P 9. Fellowship: Final Examination, P 9; Second, P 9; Third, R 2, P 7.

*Apothecaries' Hall of Ireland.*—Licence: I, R 14, P 32; II, R 7, P 24.

*University of Dublin.*—M.B.: II, R 6, P 30. M.C.: II, R 3, P 25. At the Half M.B. Examinations, the following were the results as regarded the subjects: Anatomy (Descriptive), R 16, P 26; Chemistry, R 8, P 34; Botany, R 9, P 19; Materia Medica, R 12, P 35; Physics, R 6, P 36.

*Queen's University in Ireland.*—M.D.: First Examination, R 45, P 143; Second, R 35, P 74; Third, R 29, P 44. M.C.: R 23, P 35.

#### Saturday, April 13th.

Dr. ACLAND, President, took the chair at 1 P.M.

*The University of Glasgow and the Medical Acts Amendment Bill.*—Dr. PETTIGREW presented to the Council a petition from the Senatus Academicus of the University of Glasgow against the Medical Act (1858) Amendment Bill, and requested that it be entered in the minutes of the Council.

It was moved by Mr. SIMON, seconded by Mr. BRADFORD, and agreed to:

"That the petition of the University of Glasgow be entered in the minutes."

The principal paragraphs of the petition were as follows.

"Your petitioners especially approve of its main provisions, viz.: 1. That which renders a double qualification a necessary condition of registration; and 2. That which empowers the General Medical Council to prevent the registration of a qualifying licence by any medical authority in respect of an examination lower than a fixed minimum, to be determined by the Council.

"Your petitioners are further glad to have this opportunity of expressing their satisfaction that the element of compulsory conjunction of medical authorities forms no part of this Bill. Your petitioners have always been, and still remain, of opinion that such conjunction would tend to lower the standard which the medical schools of the Scottish Universities have maintained under the existing system, whereby the examinations are conducted by a board, consisting partly of professors and partly of other examiners unconnected with the University, who are elected by the University Court in respect of their special fitness for the office.

"Your petitioners, while thus cordially approving of the main features of the Bill, venture at the same time to advert to one point in which it appears to them that the language used is open to misconstruction. Section ix, Subsection vii, seems to your petitioners to be expressed in a way which might imply the conferring on the Medical Council of a power to interfere with the right of a medical authority to exact a higher degree of knowledge than the Council might think necessary for a qualifying licence, inasmuch as it provides that the

\* Of these, ninety-seven took M.B. and C.M., nine M.B. alone, and one did not graduate.

† Of these, all took M.B. and C.M.

‡ Of these, fifty-six took M.B. and C.M., six M.B. only, and one did not graduate.

Council may, from time to time, make orders for the registration and the removal from the *Medical Register* of any diplomas 'which appear to the Council to be granted after examination by any of the medical authorities, in respect of a higher degree of knowledge than is required to obtain such qualification as entitles the holder to be registered'. The Section xiv, Subsection i, might also, in its present form, imply a similar control over a medical authority exacting a higher qualification than the Medical Council might think necessary. Your petitioners cannot suppose that it was intended that either of these clauses should bear such a construction, but their phraseology seems to require amendment. Your petitioners would also represent that the exercise of any large power of control conferred on the General Medical Council should be subject to the revision of the Privy Council.

"For the reasons above stated, your petitioners humbly pray that the essential principles of the Bill, introduced into your Lordships' House by the Lord President of the Privy Council, may become law."

*Registration of Dentists.*—A letter from Mr. John Tomes, President of the Dental Reform Committee, was read. The following are the concluding paragraphs.

"For the reasons put forward and supported by the evidence contained in the papers handed in, and for many other obvious reasons which do not need enumeration, the majority of dentists of the United Kingdom and a very great majority of those dentists who hold registered medical qualifications earnestly hope the General Medical Council will approve and support with the full weight of its influence the Dental Practitioners Bill.

"But, should the Government ultimately require that the Dental Bill shall be embodied in the Medical Bill introduced by the Duke of Richmond and Gordon, 1878, or should the Medical Council think it desirable that the Dental should be embodied in the general Bill, then, on behalf of the Dental Reform Committee, I beg to suggest that, in the presence of the well matured and very efficient system of dental education of the College of Surgeons of England, it is not desirable the Medical Council should be required to undertake to originate a new scheme of education as proposed in the Medical Bill, Clause 23 (i), but that the Council should have full power to approve, modify, or refuse its assent to the educational details from time to time proposed by the surgical bodies authorised in the Bill to grant dental qualifications; also, that all boards of examiners in dental surgery, Clause 23 (ii), shall consist of at least six persons, and that one-half of whom shall be surgeons and the other half qualified practitioners; otherwise the board might consist wholly of surgeons, the half of whom, without any practical knowledge of dental surgery, might, under Clause 23 (iii), enter their names on the *Dentists' Register* on the payment of a fee, and very imperfectly represent dentists upon the board. Throughout the Clause 23, and in Clause 22, the terms 'dentistry' and 'dental surgery' are used as though there were, or might be, some difference in their meaning. The Committee urge that the text should be made quite clear, so as to show that the terms are really synonymous. The same observation applies to the titles used by dental practitioners, and the Committee urge in this case also that the terms 'dentist', 'dental practitioner', 'dental surgeon', and 'surgeon-dentist' shall, as heretofore, and for reasons already stated, mean a person who is registered as in practice as a dentist before the passing of the Act, or a person who holds a registered dental or medical qualification.

"Clause 24 of the Dental Practitioners' Bill, exempting registered persons from serving on juries, etc.; and also Clause 31, 'provision for certain students', are omitted from the Medical Bill, 1878, both of which the Committee are strongly of opinion should be inserted.

"The draughtsman of the Dental Practitioners' Bill has prepared amendments for insertion in a copy of the Medical Bill, which would secure to the dentist the beforementioned results sought to be obtained in the Dentists' Bill, to which I beg to direct the attention of the Council.

"In conclusion, I may justly state that much time, labour, and money have been spent in bringing the Dental Practitioners' Bill into its present favourable position, and on this ground ask that, even though the Medical Council may think fit to recommend to Government its absorption into the Medical Bill, yet that the Council will not recommend that the Committee should abandon the Dentists' Bill until it is quite certain that the Medical Bill will become law."

*The Medical Act Amendment Bill.*—The Council then resolved itself into a Committee of the whole Council for the adjourned consideration of the Medical Act (1858) Amendment Bill; and proceeded, first, to consider Clause 23, relating to dentists.

The following resolutions were moved by Dr. ROLLESTON, seconded by Mr. BRADFORD, and agreed to:

"That it is desirable that provision should be made in the Medical Act (1858) Amendment Bill for the registration of Dentists."

"That it is not desirable that the Medical Council should be required to undertake to originate a new scheme of examination—rules—Section (1) of Clause 23—but that it should be entrusted with some such supervisory power as regards the educational details from time to time proposed by the medical authorities authorised in the Duke of Richmond's Bill as it already exercises with regard to other examinations."

Dr. AQUILLA SMITH moved, and Sir DOMINIC CORRIGAN seconded:

"That in paragraph (a) of Section (4) of Clause 23 of the Bill, the words 'or in dental surgery of', be omitted."

The motion was negatived.

Sir JAMES PAGET moved, Dr. ANDREW WOOD seconded, and it was resolved:

"That the Council approves the portion of the Bill that relates to the registration of dentists."

It was moved by Dr. ROLLESTON, seconded by Mr. SIMON, and agreed to:

"That the Council suggests the adoption of Clause 11 of Sir John Lubbock's Bill, viz.: 'The General Council may, if they see fit, establish in the register of dentists distinct sections for the registration of persons (not being British subjects) resident in the United Kingdom, and possessing such foreign qualifications as in the opinion of the Council are a sufficient guarantee for the possession of the requisite knowledge and skill for the efficient practice of dentistry, and for the registration of persons so resident and possessing such colonial qualifications as in the opinion of the Council are such guarantee as aforesaid; any person registered in either of such sections shall be deemed for all purposes to be registered under this Act'; instead of Subsection (5), Clause 24, of the Government Bill, viz.: 'There shall be also entered in the dentists' register, in separate alphabetical lists, such colonial and foreign dentists as are authorised by the scheme to be so registered, and the scheme shall make the like provision for the registration of colonial and foreign dentists as is made by this Act with respect to the registration of colonial and foreign practitioners in the *Medical Register*.'"

Mr. SIMON moved, Dr. ANDREW WOOD seconded, and it was resolved:

"That in Clause 7 of the Government Bill, for the words 'representing at the time of the grant thereof a degree of knowledge, as tested by examination, equal to or greater than that which at the same time was required to obtain in the United Kingdom such qualification as entitles the holder to be registered in the *Medical Register*', there should be substituted the following words:—'Furnishing, in the opinion of the Council, sufficient guarantees of the possession of the requisite knowledge and skill for the efficient practice of medicine and surgery.'"

Dr. ANDREW WOOD moved, and Mr. TEALE seconded:

"That with respect to Clause 5 of the Bill, colonial practitioners must have practised five years after obtaining their diploma, or shall be required to pass the final examination of one of the medical authorities of the United Kingdom. In the latter case, they should be entitled to be placed upon the general *Medical Register*."

Mr. SIMON moved, as an amendment, and Dr. ROLLESTON seconded:

"That the Council is of opinion that Clauses 5 and 6 of the Bill should be brought into conformity with its resolutions of last year." The amendment was negatived.

Mr. SIMON required that the names and numbers of those who voted for and against the amendment respectively, and of those who did not vote, be taken down.

*Majority, 11.*—Dr. Humphry, Dr. Haldane, Dr. Andrew Wood, Dr. Scott Orr, Mr. Turner, Dr. Pettigrew, Dr. Aquilla Smith, Mr. Macnamara, Dr. Apjohn, Sir Dominic Corrigan, Mr. Teale.

*Minority, 7.*—Mr. Bradford, Dr. Rolleston, Dr. Pyle, Dr. Storrar, Dr. Lect, Mr. Simon, Dr. Hudson.

*Did not vote, 2.*—The President, Sir James Paget.

*Absent, 4.*—Dr. Pitman, Dr. Quain, Sir William Gull, Dr. Fergus.

On the motion of Dr. ANDREW WOOD, the further consideration of the subject of foreign and colonial degrees and diplomas was adjourned till Monday.

The Council then resumed.

It was moved by Sir WILLIAM GULL, seconded by Dr. ROLLESTON, and agreed to:

"That the President, Dr. Andrew Wood, and Dr. Humphry be requested to communicate to the Lord President of the Privy Council the resolutions relating to the Medical Acts (1858) Amendment Bill, which have been passed during the present session of the Council."

*Monday, April 15th.*

Dr. ACLAND, President, took the chair at 2 P.M.

*Deputation to the Lord President.*—The PRESIDENT stated that he had laid before the Lord President of the Privy Council the following observations.

"The Medical Council deputed the President, Dr. Humphry, and Dr. Andrew Wood to present to your Grace certain resolutions which they have arrived at. The Council met on April 10th to consider the letter which your Grace forwarded, with copies of the Medical Act (1858) Amendment Bill, read in the House of Lords on March 19th. All the subjects on which the Council last year addressed your Grace are dealt with in this Bill, viz.: 1. The recognition of foreign and colonial qualifications in England; 2. The privileges of women in regard to medical qualifications; 3. The appropriation of penalties under the Medical Act; 4. To some extent the education of Midwives; 5. And, indirectly, the emendation of the law affecting certificates of lunacy. After the second reading of the Bill, the Council may have to suggest to your Grace's consideration certain amendments in various clauses relating to these subjects, and to some minor points in the Bill, prior to the consideration in Committee.

"The Council are aware that your Grace was unwilling to bring in any Government Bill which did not deal with all the chief subjects that were known to need attention in regard to medical legislation. They find, accordingly, in the Bill clauses having reference to subjects that are admitted to be of importance, and to need settlement, other than those named last year by the Council.

"They find clauses relating to the mode of conducting examinations in the United Kingdom, and to framing examination rules.

"They perceive that the permissive principles of combination of any of the licensing bodies is continued with modifications. On this subject a resolution has been passed by the Council, which forms Clause 3 of the Minutes for April 12th, 1878.

"If the Bill pass in its present form, it would, in the opinion of the majority of the Council, be necessary to make such modifications in the rules as are set forth in the resolutions in Clauses 5, 6, 9 of the Council's Minutes for April 12th, 1878.

"On the subject of the registration of colonial practitioners and other subjects therein, the Council is engaged now.

"On the subject of dentists they have passed resolutions which form Clauses 6, 7, 9, 10, 11 of the Council's Minutes for April 13th, 1878.

"As regards the registration of midwives, they have not yet had time before the second reading to pass any resolution, but they have already notified to your Grace that the Council, without assenting in all details to the scheme of the Obstetrical Society, is of opinion, with the society, that it would be desirable to provide by legislation for the following two objects: First, that means under legal sanction should be provided for giving credentials of qualification to competent midwives; and, secondly, that the lives of women in labour should, so far as practicable, be protected from the incompetent; and to-morrow they will receive a deputation from the Obstetrical Society as to the details of their proposal.

"The Council are still engaged in considering the remainder of the clauses in the Bill, and will further communicate with your Grace thereon after the Easter recess."

"Upon that, his Grace said that he would give the fullest attention and consideration to all those particulars upon which the Council had already resolved, and to any further resolutions which the Council might pass at such times as the Council thinks fit: that is, either during the present session or at any subsequent session that may take place at the will of the Council, if it takes place before the House of Lords goes into committee on this Bill. He then said that he was going to bring forward the second reading this afternoon, and that, in consequence of that, and some important business in which he is engaged, he was unable to receive the deputation of the Obstetrical Society, which he had wished to do this afternoon. He was so occupied that it was impossible for him to do so; but, as the Easter recess begins to-morrow, and he would not be able to see them at all now until after the Easter recess, having understood that they were to meet this Council to-morrow, he would be happy to receive through this Council any further communication on the subject, if there be any to be forwarded after the interview with the Obstetrical Society.

"Then he added that he had every reason for hoping that this evening the second reading of the Bill would be passed, and then that in that case he would introduce the Bill in committee, for the consideration of all the amendments which had been presented to him, and for their full discussion at the earliest possible period at which it could be done. Considering the other arrangements of the Government, and the work before the House, the earliest day at which he could undertake to do this would be on the 20th of May next, and, in his Grace's judgment, if the discussion could not successfully take place on the 20th May or thereabouts, there would be no chance of the Bill passing this year; that he would give his best attention to all amendments which should come before him before the 20th of May, and on that day he would proceed with the consideration of the Bill in committee.

"I thought it my duty to say, and I trust the Council, as well as my colleagues, will not think I went too far in this statement, that we had not yet considered fully the whole of the Bill; but I was quite sure I expressed the individual feelings of the members of the Council, that whatever opinions there might be as to the value of the Bill, we were all very sensible of the great trouble he had taken."

Mr. TEALE moved, Mr. MACNAMARA seconded, and it was resolved:

"That the foregoing communications from the President be entered in the minutes."

*The British Medical Association and the Medical Acts Amendment Bill.*—The following further communications from Dr. Edward Waters was read.

"14, Nicholas Street, Chester, April 12th, 1878.

"Sir,—I beg to acknowledge the receipt of your letter of the 11th instant.

"I am very happy to hear that the views of the Association will be submitted to the General Medical Council during its present session. I hope the Council will not negative the proposals without giving an opportunity to the Medical Reform Committee of defending them.

"The Committee will have a meeting in London on Wednesday next, and some of its members might possibly attend before 12 o'clock on that day. (Signed) "EDWARD WATERS.

"W. J. C. Miller, Esq."

It was moved by Mr. TEALE, seconded by Sir WILLIAM GULL, and agreed to:

"That, in reply to Dr. Waters's letter of April 12th, the President be authorised to receive Dr. Waters and the members of the Medical Reform Committee on Wednesday, at 11 o'clock, in order to hear their views of the proposals referred to in Dr. Waters's letter, and that such members of the General Medical Council as desire it shall be present at the interview."

*The Medical Acts Amendment Bill.*—The Council resolved itself into a Committee of the whole Council for the adjourned consideration of the Medical Act (1858) Amendment Bill.

Dr. PITMAN moved, and Dr. QUAIN seconded:

"That the Council adheres to its resolution of last year in reference to the registration of colonial diplomas."

Sir WILLIAM GULL moved as an amendment, and Dr. HUDSON seconded:

"That where a person who has been *bona fide* domiciled in any British possession can show evidence of holding some recognised medical diploma or diplomas (as hereinafter defined), granted in such British possession, and which may be satisfactory to the Medical Council, and that he is of good character, such person shall upon payment of the registration fee be entitled, without examination in the United Kingdom, to be registered as a colonial practitioner in the *Medical Register*."

The amendment was negatived.

Dr. ANDREW WOOD moved as a second amendment, and Mr. TEALE seconded:

"That in Clause 5, lines 1 to 4, of the Bill, for the words, 'Where a person who either is not domiciled in the United Kingdom, or has practised medicine or surgery, or a branch of medicine or surgery, for more than ten years elsewhere than in the United Kingdom', there should be substituted the following words: 'Where a person has been domiciled in a British possession for two years immediately preceding the granting of his diploma.'"

The amendment was carried, and, having been put as a substantive motion, the following amendment was moved by Mr. SIMON and seconded by Dr. STORRAR:

"That where a person who has been *bona fide* resident in a British possession outside the United Kingdom shows that he is of good character, and holds a recognised diploma or diplomas (as hereinafter defined), granted in a British possession, such person shall, upon payment of the registration fee, be entitled, without examination in the United Kingdom, to be registered as a colonial practitioner in the *Medical Register*."

This amendment was carried, and, having been put as a substantive motion, was agreed to.

*Executive Committee.*—The Council resumed, and balloted for the Executive Committee, whereupon the following members were found to be duly elected.

Sir James Paget; Dr. Humphry; Dr. Andrew Wood; Dr. Aquilla Smith; Dr. Quain; Mr. Simon.

*Medical Acts' Amendment Bill.*—The Council resolved itself into a Committee of the whole Council for the further consideration of the Bill; and the following resolutions were agreed to:

Moved by Mr. SIMON, seconded by Sir JAMES PAGET, and agreed to:

"That Clause 6 be in substance approved."

Moved by Mr. SIMON, seconded by Sir W. GULL, and agreed to:

"That Clause 8 be in substance approved."

Moved by Dr. ANDREW WOOD, seconded by Mr. TURNER, and agreed to:

"That Clauses 9, 10, 11, and 12, be in substance approved."

Moved by Dr. APJOHN, seconded by Mr. SIMON, and agreed to:

"That questions relating to the erasure of names from the *Medical Register* for infamous or disgraceful conduct in a professional respect ought, in the opinion of the Council, to be reserved for decision by the general body of the Council, and that it be recommended to the Lord President to amend Clause 13 of his Bill accordingly."

Moved by Dr. HUMPHRY, seconded by Dr. AQUILLA SMITH, and agreed to:

"That it is desirable the power of erasing from the *Medical Register* the name of any person who has been convicted in a court of law of a felony or misdemeanour, be deputed to a Committee of the Council."

The Council then resumed.

*Restoration of a Name to the Register.*—The name of Laurence P. J. Finigan, which had been erased in conformity with Section XIV of the Medical Act, was restored to the Register.

*The Society of Apothecaries and the Medical Act Amendment Bill.*—A letter addressed to the President of the Council by the Master of the Society of Apothecaries, enclosing a copy of a letter to the Lord President of the Privy Council, was read, and on the motion of Mr. BRADFORD, seconded by Dr. ANDREW WOOD, was ordered to be entered on the minutes. The letter to the Lord President was to the following effect.

"The Society consider that, if the 14th section of that Bill should become law, it will operate very much to their prejudice.

"In the first place, the privilege which the Society enjoy at the present time of framing their own examination-rules would be taken away from them, and placed in the hands of the General Medical Council. Such a result, in the opinion of the Society, would be a serious blow, not only to their own independence, but to that of all the existing medical authorities. But in the second place the Society occupy a peculiar position as regards this section, from having granted some time since their licence to a woman.

"The present Bill, by not repealing the 5th Clause of the Society's Act of 1874, while it repeals an exactly similar Clause in the College of Surgeons' Act of 1875, evidently has not lost sight of this fact.

"Assuming, then, an obligation to exist on the part of the Society to examine women, the 14th Section of the Bill would, on the one hand, compel the Society to examine women on terms and conditions differing from those to which men would be subjected, and, on the other hand, would prevent them from framing the rules for their examination.

"The anomalous position in which the Society would be placed by such legislation is obvious. The Society, therefore, cannot but think that your Grace will recognise the justice of their objection to the principle of a medical authority under an obligation to admit women to examination being deprived of the right of framing the rules under which such examination should be conducted.

"There is a further matter of less importance to which I am desired to call your Grace's attention. It is not altogether clear from the 21st Section of the Bill whether the Society (if they do not form part of a conjoint board) could alter by statute or by-law the constitution, functions, and duties of their present examining body, or whether the Society would remain in the same position as they are under their Amendment Act of 1874, which enables them only to alter such constitution, functions, and duties in the event of their forming part of a conjoint board.

"Upon the general features of the Bill, the Society desire me to state that their views are in accordance with those which have already been expressed to your Grace by the Royal College of Physicians and Surgeons."

*Army Surgeons.*—On the motion of Mr. MACNAMARA, seconded by Dr. AQUILLA SMITH, a letter addressed by the Royal College of Surgeons in Ireland to Mr. Ralph Thomson, Assistant Under-Secretary of State, War Office, a copy of which had been sent to the Medical Council, was ordered to be received, and entered on the minutes.

"Dublin, April 11th, 1878.

"Sir,—I am directed by the President and Council of the Royal College of Surgeons in Ireland, in reply to your letter of the 21st ultimo (1877), requesting that they would 'favour the Right Hon. the Secretary of State for War unreservedly with their opinion as to the specific causes which produce the existing difficulty in obtaining candi-

dates for the Army Medical Department', to state, that the President and Council have had the subjects therein referred to under their anxious consideration for a lengthened period, as shown in their memorial presented by deputation to the Right Hon. the Secretary of State for War upon the 3rd of June, 1875.

"Since the receipt of your communication the President and Council have taken further steps for the purpose of ascertaining accurately the causes which render the Army Medical Service now so unpopular—which produce the dissatisfaction that exists amongst those serving in it, and which deter eligible candidates from joining. These are—1. The short service scheme now in existence; 2. The abolition of the regimental system; 3. The frequent changes in warrants, after they have been published under royal authority with Her Majesty's signature, and on faith of the permanency of which warrants medical officers have accepted service: this has produced an utter want of confidence in and distrust of the service; 4. The differences which are made between combatant and medical officers in regard to ordinary and sick leave; 5. The almost absolute refusal to medical officers of the privilege to exchange; 6. The virtual withdrawal of forage allowance from those by rank entitled to it; 7. The quarters allotted to medical officers in barracks being almost invariably regimental, whilst they, as departmental officers, are supposed to be entitled to departmental quarters; 8. The discomfort caused to medical officers by want of a soldier servant, whilst the sum allowed in lieu thereof is incapable of providing a civilian; 9. The length of time (five-and-twenty years) before the medical officers can claim a right to retire from the service on adequate pension; 10. The roster, as now kept, which has been withdrawn from public inspection, so that no officer can tell how he stands in regard to foreign service; whereas formerly this document was exposed in the waiting-room at Whitehall Yard for each medical officer's specific information.

"These are the points which deter candidates from coming forward, and the President and Council feel assured that, until ameliorated, entrance into the Army Medical Service will be avoided by the desirable class of students.

"The President and Council, in conclusion, deem it right to impress upon the consideration of the Right Hon. the Secretary of State for War the fact that at the present time so many varied and lucrative outlets in the Civil Service present themselves for the acceptance of the junior members of the profession, that it becomes the more imperative to improve the condition of army and navy medical officers, so as to enable the naval and military services to compete on favourable terms with the Civil for the obtaining of the best and most highly-educated students.—(Signed) J. STANNUS HUGHES, Secretary to Council."

On Tuesday, a deputation from the Obstetrical Society of London, consisting of Dr. West (President), Dr. Barnes, Dr. Priestley, Dr. Aveling, Dr. J. Williams, and Dr. Murray, had an interview with the Council to explain the scheme proposed by the Society for the Registration and examination of Midwives.

The Council went into Committee on the Medical Acts Amendment Bill, and passed various resolutions, principally with reference to the clauses of the Bill providing for the registration of midwives.

The Registrar was directed to remove from the *Register* the names of John Baxter Langley, John Campbell White, and Owen Patrick O'Hare, who had been convicted in courts of law of certain offences.

On Wednesday, at 11 a.m., the President and several members of the Council received Dr. Edward Waters, Chairman of the Medical Reform Committee of the British Medical Association, and several other members of the Committee, in pursuance of the resolution passed at the meeting on Monday. Dr. Waters explained the action of the Association and Committee in regard to medical reform, and urged on the Council the views of the Committee with regard to the representation of the profession in the Medical Council.

At 2 p.m. the Council again went into Committee on the Bill, after which various ordinary business was transacted, and the session came to an end.

*TREATMENT OF WHOOPING-COUGH BY CARBOLIC ACID.*—Dr. Orville of Lille publishes (*Revue de Thérap. Méd.-Chir.*) the record of twenty-five cases of whooping-cough treated by inhalations of carbolic acid contained in a wide-mouthed bottle. When fever indicates an inflammatory lesion, this plan must not be resorted to. The bottle is placed close to the mouth of the little patient during the paroxysm of cough, at the moment when the whistling inspiration which follows prolonged expiration is produced. The inspiration of the vapour of the carbolic acid is thus very energetic.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, APRIL 20TH, 1878.

THE MEDICAL ACT AMENDMENT BILL.

THE Medical Act Amendment Bill of the Duke of Richmond has passed its second reading in the House of Lords as a matter of course. But by this time the Lord President has received sufficient intimation of the general sense of the profession concerning its deficiencies, and the future fate of the Bill will, of course, turn upon the steps taken in Committee to give effect to the objections laid before the Lord President on two subjects. We pointed out these in the first instance, and even by anticipation, knowing what had been the course of the preliminary negotiations and the result of the pressure upon the Duke from highly influential quarters. The clauses which stood in the original Bill as first drafted, included provision for compulsory joint Boards, and a minimum uniform and complete qualification for the three kingdoms. These clauses were modelled upon those of Lord Ripon's Bill, which passed the House of Lords and had a second reading in the House of Commons in 1870, and were accepted as satisfactory then by the General Medical Council and by the British Medical Association. These clauses have been withdrawn under pressure, which, as we at the time intimated, proceeded mainly from the Scottish universities and examining bodies. The course of the debate in the General Medical Council has shown those bodies firm and unwavering in their opposition to such provisions; and they were joined in their opposition by a majority of the representatives of the Irish bodies. On the other hand, the Crown representatives (with one exception) and the representatives of the English bodies formed a steady majority in favour of the principle of conjoint boards and an uniform minimum qualification. The Council, therefore, as a whole, and each of the London examining bodies separately, have, by deputations or otherwise, expressed their views of compulsory clauses to the Duke of Richmond.

The Medical Reform Committee of the British Medical Association has taken the opportunity of arranging a *plébiscite* by printed interrogations addressed to every member of the profession, asking their approval of, first, the principle of conjoint examining boards and uniform minimum qualifications; second, the principle of direct representation of the profession on the General Medical Council, to which we have lately referred at length. They have also addressed the Duke of Richmond and the General Medical Council on this subject. Thus these questions are being now very effectually raised; and at least we may anticipate for them a full Parliamentary discussion. Of the probable tenour of this discussion, a good forecast may be made from what we have here stated and from the speech of the Marquis of Ripon.

Unless the Duke of Richmond is prepared to substitute the compulsory for the permissive principle in respect to conjoint examinations, and also to accept amendments providing for the direct representation of registered medical practitioners on the General Medical Council, he must be prepared to find his Bill meet with such opposition in the House of Commons as will give it little chance of becoming law.

BACTERIOID RELATIONS OF SPLENIC FEVER.

WE mentioned, in a recent number of the JOURNAL, that M. Colin read, at a recent meeting of the Paris Academy of Medicine, a paper on the Successive Development of Anthracoid Diseases.

Our readers may remember that M. Colin once made bold to say that putrefaction was not in any way related to the growth of bacteria; in fact, that it resulted from chemical changes. As a proof of this, he stated that no bacteria were found in putrefying eggs. This was easily refuted by M. Pasteur, who proved conclusively to a commission that, when eggs were putrefying, bacteria were always present. What M. Colin once endeavoured to prove to be true of ordinary putrefaction, he now states to be true of specific diseases; but just as he was wrong in stating that putrefaction was the result of chemical changes, so we may safely state that he is now still further mistaken when he believes that specific diseases are due to a poison which originates and increases independently of the presence of specific organisms. This is not a new theory, for only lately, in the London Chemical Society, a paper was read showing that splenic fever was altogether and only due to a poison which resulted from chemical changes.

But just as M. Pasteur and Dr. Burdon Sanderson have proved that putrefaction is the result of fermentative changes set up by septic bacteria, as certainly as the vinous fermentation is set up by the yeast-plant, and the lactic acid fermentation, as shown by Mr. Lister, by *bacterium lactis*, so, notwithstanding what M. Colin has said, it may, we think, be predicated that splenic fever is due to the growth and development of *Bacillus anthracis*.

This anticipation we may express before the commission meets to decide the point at issue between M. Pasteur and M. Colin, not only because we are familiar with the splendid work done by Koch and others, but also because we believe that, at University College, Dr. Ewart has made out, not only that splenic fever invariably follows when the smallest possible number of the spores or rods of *Bacillus anthracis* are introduced into the subcutaneous tissue of a small animal, but especially because he has been able to trace the rods from the point of inoculation along the lymph-channels; and further, by cultivating glandular tissue, in which, when first examined, neither rods nor spores were visible, he has developed the well-known spore-bearing anthrax filaments.

Ordinary septic bacteria are in themselves innocuous when introduced into a healthy animal; but when introduced into an animal having at any part degenerated tissue, they lead to fermentative changes—to putrefaction, it may be septicæmia. In other words, ordinary bacteria are harmless while they simply live in healthy tissues or fluids; but when provided with suitable nourishment, and thus enabled to multiply, they, as they live and move, produce a virus which, besides setting up putrefactive changes, may lead to septicæmia or pyæmia.

Specific bacteria differ from septic bacteria: for, when introduced into a healthy animal, they at once give rise to specific diseases. In the presence of septic bacteria, *Bacillus anthracis* is incapable of developing, not because the existence of ordinary bacteria indicates that putrefactive changes are going on, but because, in the struggle for life, septic bacteria overcome the less tenacious and generally motionless bacilli. M. Colin states that from the point of inoculation a virus passes to the nearest glands. The glands increase in size, and the poison being regenerated in them, and passing on to the next group of glands, forms other infective centres. In such glands, M. Colin can find no evidence of the existence of bacilli.

We know that ordinary bacteria do not mechanically cause putrefaction. They have much the same relation to putrefaction as the yeast-plant has to drunkenness; and what is true of septic bacteria seems to be true of specific bacteria; for Dr. Ewart has made out that splenic fever is not, as has been supposed, due to the mechanical action of the

bacilli, but due, in all probability, to a specific virus manufactured by them. We say a specific virus, because it sets up a specific disease, which can be easily distinguished from septicæmia and pyæmia. If this be so, even if in the glands no bacteria were found, M. Colin would not be justified in assuming that anthrax could originate and spread in the absence of bacteria; for a virus formed at the seat of inoculation might reach the glands sooner than the rods which produced it.

In justice to M. Pasteur, however, it must be said that in all probability the virulent fluid is taken up and carried away by the veins around the seat of its formation, thus entering directly the general circulation; and that the bacilli gradually find their way through the lymphatics into the large veins, and from them find their way into, and more or less block up, the small vessels and capillaries of the lungs and other organs.

We know that the virus which produces septicæmia never increases after its introduction into the system, and that the results it leads to are always in ratio to the amount at first introduced. If, then, in a similar way, splenic fever be caused by a virus formed by bacilli, we may infer that the virus has not, in itself, the power of self-regeneration in the absence of the bacilli, as stated by M. Colin; and, even if it had, we are unable to see how M. Colin can prove the possibility of such regeneration until he is able to separate the virus from the bacilli which manufacture it.

#### THE ARMY MEDICAL DEPARTMENT.

ONE of the objections urged by army medical officers to the present organisation of their department, when compared with the regimental system, refers to a subject which might at first be regarded as one of very minor importance; but when it is fully examined, it may be easily understood that it is not so. This is the matter of personal servants. Under the existing system, an allowance is made to the medical officer for providing a private servant to keep his uniform and appointments in order, and to attend to his personal wants; under the regimental system, a military servant was provided for him for these purposes. This, however, is really no new subject of complaint in the Army Medical Department; for under the old system, when the medical officers were divided into two sections, one belonging to the regiments, the other to the staff of the army, the same grievance existed, though it was not so widely distributed. The staff medical officers constantly experienced great difficulties in engaging civilian servants; or, if engaged, in inducing them to stay in their situations, owing to the peculiar circumstances of military life. Some of the rules and conditions in quarters are opposed to the ideas of independence entertained by civilian "helps", and they miss many of the comforts and regular habits which reconcile them to service in established homes. Hence, even while employed in England in time of peace, the "servant difficulty" was a constant source of vexation to the staff medical officer; and in campaigning, the trouble arising from it became aggravated in a tenfold degree. In the field, indeed, the difficulties in the way of keeping a non-military servant were almost insuperable. We read of staff medical officers, during the Crimean war, being reduced, from want of servants, to cook their own food and clean their own boots. On the other hand, the regimental medical officer could always rely on having the requisite attendance. His servant might occasionally be taken away from him for a time for inspection or for parade, or perhaps even to fight; but whether he were removed merely as a temporary measure, or whether he were removed altogether by the enemy, there was no doubt about some other being sent to replace the absentee. The daily necessities of the regimental medical officer were sure to be attended to, whatever else might happen; the staff medical officer had no surety of the kind, he could only depend upon himself, and that only so far as he might be able to find time from his regular occupations. What was at that time true of the staff

medical officers, is now applicable to all medical officers of the army, and hence the prominence which this grievance has assumed.

A circumstance which has increased the dissatisfaction of the medical officers on the subject of servants is the smallness of the allowance granted by the War Office as a set-off against the discontinuance of the services of a military servant. The sum given to the medical officer for obtaining a civilian servant is one shilling a day: a pittance which is, of course, quite inadequate as a payment for any man of decent character or condition. The soldier-servant received his daily pay, lodging, rations, fuel, and light from the Government, so that a very small additional amount from the officer having the use of his personal services was a sufficient compensation for this particular employment. It is almost farcical to speak of a shilling a day as an "allowance in lieu of a soldier-servant", under such circumstances. This amount, too, is the allowance irrespective of rank; the Deputy Surgeon-General gets no higher rate than the surgeon who has just joined in this regard. No increase is made in the allowance, although the medical officer may have to keep a horse and obtains forage from the Commissariat Department for it, or even if, as a Deputy Surgeon-General, he has two horses to keep. The allowance given in all cases is the sum of one shilling a day to cover all servants—grooms as well as personal servants. There seems to be an amount of absurdity about the whole affair, as well as a parsimoniousness, which is quite surprising; and it can hardly be a matter of wonder that it has given rise to a great deal of heartburning and discontent. The impracticability of hiring a servant on the terms of the Government grant, and the difficulty of keeping one even at a much higher rate of pay in military quarters, is one of the things which, like the want of a mess, exerts a powerful influence in making the daily life of a staff medical officer one of irksome discomfort, and which makes him look upon the position of a regimental officer as one of comparative ease and happiness. Cannot all officers in the army have soldier-servants assigned to them? If they are to some, why not to others? Experience has shown that officers must have military servants in time of war, if they are to have any servants at all; and the need is only a little less urgent in time of peace under the circumstances in which officers are placed and have to live.

We commend this subject to the attention of the committee that is now inquiring into the causes which prevent commissions in the medical department from being sought after and competed for as they are in other branches of the military service.

THE Royal College of Physicians of London has, on the motion of Dr. Quain, the Senior Censor, voted a sum of one hundred guineas to the fund for erecting a statue to the memory of Harvey on the occasion of his tercentenary. On the motion of the same physician, it was resolved that the College will hold during the present season a banquet in the library, in honour of the same anniversary.

AMONGST the gentlemen examined and admitted members of the Royal College of Surgeons on the 16th instant, will be seen the name of Mr. Kanehiro Takaki of Tokio, Japan. This gentleman, who is the second native of Japan in the calendar of the College, has already passed the primary examination for the higher distinction of Fellow.

AT the meeting of the Hospital Saturday Fund, Mr. John Hughes, Chairman, said that, three weeks hence, about eighty thousand collecting sheets would be distributed. They hoped to collect £10,000 on the first Saturday in September next; and it was arranged, with the view of calling further attention to the subject of this fund, to hold central meetings in order to secure sympathy for and give publicity to the work. A motion was adopted asking the Lord Mayor to call a meeting at the Mansion House; and it was also agreed that street-collections be made by ladies on Hospital Saturday. The latter we consider an objectionable element in the method of canvassing adopted by this fund.

A DEATH from hydrophobia is reported from the United Hospital, Bath.

MR. JOHN SIMON will preside at the distribution of prizes in the Faculty of Medicine at University College on Monday, May 20th, at 3 P.M.

DR. RHYS WILLIAMS, long and well known as the efficient Superintendent of Bethlehem Hospital, has been appointed Commissioner of Lunacy in lieu of Dr. Wilkes, who has retired after a long term of office. The excellent rule has been adopted of late years, in making these appointments, of selecting physicians who have had long experience of asylum management and the treatment of the insane.

DR. G. H. SAVAGE, who has for some years filled the office of Assistant-Physician at Bethlehem Hospital with great satisfaction to the governors and much professional distinction, is a candidate for the succession to Dr. Rhys Williams as Resident Physician.

THE nominations by the Council of the Royal Society to the fellowship of the Society include the names of Dr. Hughlings Jackson, the well-known Physician of the London Hospital, to whom the first Marshall Hall premium of the Royal Medical and Chirurgical Society was lately awarded for researches and original studies on the diseases of the nervous system; and Mr. Schäfer, the Assistant Professor of Histology at University College, whose excellent *Handbook of Practical Histology* and numerous researches in the laboratory of Professor Sanderson have proved his skill and earnestness in biological teaching and study.

THE Royal College of Surgeons in Ireland has addressed an extremely able statement of the grievances of the army medical officers to the Secretary of State at War, in answer to his circular to which we have already referred. The statement enumerates the points to which we have already drawn attention; and we have no doubt that, coming from the examining body which licences probably the largest number of candidates for these appointments, the representation will have great weight. The Irish College of Surgeons has always been conspicuous for the interest it has taken in this subject, and on this occasion it has acted in a manner worthy of its precedents.

OUR members generally, and especially those resident in Wales and in the metropolis, will join us in congratulating our distinguished associate Mr. W. H. Michael, F.R.C.S. and Barrister-at-Law, on his nomination as Q.C. Mr. Michael's career as a medical practitioner in Wales showed always the same intellectual power which has led him to eminent success at the parliamentary bar. His services to the Association in its efforts to advance public health law have been continuous and pre-eminent. Editorially, we have never applied to him in vain for assistance in dealing with these subjects, in which his varied legal and medical acquirements and intimate study have rendered him a great authority; and his services to the Joint State Medicine Committee of the British Medical and Social Science Associations have been and are of national value. Nor have the pressing claims on time of large parliamentary practice ever prevented Mr. Michael from giving such aid freely, voluntarily, and with the most hearty cordiality.

A WORD of satisfaction may also be expressed at the elevation of Mr. W. T. Charley, M.P., to the post of Common Serjeant for the City of London. We are indebted very largely to Mr. Charley for active, unceasing, and successful efforts to obtain parliamentary attention to the evils of baby-farming and the destruction of infant life, which were thoroughly traced out and exposed by the investigation originated and conducted for this JOURNAL by Mr. Ernest Hart, with the valuable personal aid of Dr. Wiltshire and Mr. J. B. Curguenven. Mr. Charley's perseverance and strenuous earnestness triumphed over much obstruction and opposition in obtaining a Select Committee of the House of Commons, before which the medical evidence of the

three gentlemen named was taken, and procured the passage of the Infant Life Protection Act. Since then, Mr. Charley has been engaged in other useful legislation with the object of protecting infant life, for which he has twice secured the assent of the Government and the approval of the House of Commons, but which, owing to the difficulties which impede the Bills of private members, has not yet reached the final form of law. The work, however, is more than half done, and the greater authority of his new position will certainly be effectively used to promote these useful measures. Mr. Charley has always shown great sympathy for measures of medical reform, and a just appreciation of the importance of medical co-operation in measures of social improvement.

CAPTAIN D. C. HARRIS, Assistant Commissioner of Police, has issued a report, which is printed as a parliamentary paper, on the working of the Contagious Diseases Acts during 1877. The report is most favourable, and adds that, besides the great result of diminishing disease attained by these Acts, much good is accomplished in reclaiming young girls who have begun an immoral life, and in preventing others from adopting it.

THE sum of £1,000 has been handed over to the authorities of the General Hospital, Birmingham, by Dr. Balthazar Foster, under the will of the late Mr. Frederick Cohen, for the foundation of a fund for the relief of necessitous patients leaving the hospital. Samaritan funds of hospitals are among the most valuable adjuncts of their usefulness, and, as a rule, they do not sufficiently share in the munificence of benefactors.

OUR Manchester correspondent writes to us:—The following appointments have recently been made in Manchester. Dr. Little has been appointed Lecturer on Ophthalmology at Owens College; Dr. Edge and Dr. Reid have been elected Physicians to the Salford Hospital; Dr. Boddy and Mr. Buckley have been made Assistant-Physician and Assistant-Surgeon to the Clinical Hospital. Nominations to the four vacant offices connected with the Infirmary took place this week, but they are not confirmed until next Monday. —Mrs. Catherine Dauntsey Foxton, amongst other bequests, has left £1,000 to the Infirmary, £1,000 to the Convalescent Hospital at Cheadle, and £500 to St. Mary's Hospital. She has also left £5,000 to be equally divided between a legal and a medical scholarship, to be designated the Dauntsey Scholarships. —The plans for altering the Infirmary and improving the drainage are to be commenced at once. The estimates are about £5,000. —The recent epidemic of typhoid fever at Moss Side, Manchester, seems to have been very closely traced to milk-contamination by Dr. Sutcliffe, the Health Officer. The epidemic, never very extensive or deadly, is now at an end.

#### WATER-ANALYSIS.

MR. WANKLYN makes the announcement that, working conjointly with Mr. Cooper, an important improvement in water-analysis has been made; and that, in point of fact, the cellulose or modified cellulose in drinking-water can now be estimated, just as heretofore the nitrogenous matters have been dealt with.

#### THE SOCIETY OF MUTUAL DISSECTION.

OUR Paris correspondent writes:—In a former letter, I informed you of a new Society that was founded in Paris, called the Société d'Autopsie Mutuelle, by the statutes of which its adherents were required to leave, by a will made out in due form, their bodies at the disposal of the above Society for examination *post mortem*. M. Louis Asseline, editor of the *Rapport*, an extremely Radical paper, who died suddenly last week, seems to be the first member who has been brought under the operation of the new Society. Professor Paul Broca was charged with the necropsy, and the following was the result of the examination. The left auricle of the heart was found ruptured in consequence of fatty degeneration of this organ,

the muscular fibres of which had almost entirely disappeared. The brain was of an immense size, and weighed 1,400 *grammes*, which is considerably above the average. It was remarked that ossification of the fronto-parietal suture had not taken place, although the deceased had reached the age (forty-nine) when it is usually found so in ordinary circumstances. Moreover, it has been observed that, in the inferior races, or in uncultured individuals, ossification of the sutures occurs much earlier than in the white races; and the deduction from this is, that intellectual work so develops the brain as to retard or prevent the complete ossification of the cranial sutures. This, however, requires to be confirmed, as the case has not, to our knowledge, been observed in other similar conditions.

#### PROVINCIAL REPRESENTATION IN THE COLLEGE OF SURGEONS.

MR. CURLING's letter (which we publish in another column) of objections to the election of provincial surgeons on the Council of the College of Surgeons of England, renews the old arguments to which we have never been able to attach much weight. They cannot attend committees as much as metropolitan surgeons: the provincial schools and provincial interests are sufficiently well represented by metropolitan members of Council, for science knows no local distinctions. All this is not new; and its chief interest lies in the fact that a surgeon so liberal-minded, thoughtful, and free from parochialism as Mr. Curling, thinks it worth while, at this time of day, to repeat it. The College committee work is not likely to suffer from the disability of the small proportion of provincial men to attend to it as fully as London men: a technical difficulty of that kind has never yet in public affairs been held to prevail; and there can be few greater signs of the weakness of the general argument than when this is put prominently forward. As to the larger suggestion, that provincial interests are perfectly well represented by metropolitan men, the answer is trite, obvious, and conclusive. They may be; but, as a rule, men prefer to be represented by themselves, and it is a rule, which has in its favour universal experience as well as logical presumption, that the more thoroughly all the various elements of a constituency are included in a representative body, the more satisfactory and efficient is the representation.

#### MR. POLLOCK ON CANVASSING AT COLLEGE ELECTIONS.

WE have a letter from Mr. George Pollock of St. George's Hospital, enclosing a correspondence with Mr. Bradley of Manchester, in which Mr. Pollock reiterates his well-known objection to "canvassing" for signatures or support. We fear that the pressure of space this week will prevent us from doing full justice to this subject. It is, however, well known that the present mode of open election at the College renders such a proceeding almost essential; that it has been adopted in a great majority of cases for many years; and that, for example, the friends of Sir William Fergusson, Mr. Prescott Hewett, Mr. Erichsen—to mention only names of the highest distinction—felt compelled to resort to some organised means of bringing forward those eminent men when their election was desired. At the College of Physicians, as at the Royal Society, a house-list is prepared for submission to the fellows. But the evils of canvassing, such as they are, are inseparable from open voting by a scattered constituency. It is, therefore, the mode of voting at the College of Surgeons which Mr. Pollock must seek to alter, if any other consequent change is first desired; otherwise, he would only succeed in substituting for canvassing caucusing, which is still more objectionable, especially to those who do not happen to reside within the limits of the caucus.

#### LISTERIAN OVARIOTOMY.

DR. MARION SIMS, who has recently spent a fortnight in London, reports that during that time he has been present at eleven operations of ovariectomy. They were performed under Mr. Lister's antiseptic precautions. Several were in ordinary hospital practice—two of them at St. Thomas's Hospital; and, at the time of his leaving London, all were doing well. The reports which we have already published from

Dr. Keith of Edinburgh, Mr. Knowsley Thornton of the Samaritan Hospital, and from Dr. Schroeder in Berlin, indicate how large an element of safety the adoption of Mr. Lister's dressing appears to introduce into the practice of ovariectomy in ordinary hospital buildings. The degree of danger arising from atmospheric contamination in large hospitals has, up to the present time, appeared so largely to add to the perils of the operation as almost formally to contraindicate its performance in such a *locale*. Mr. Knowsley Thornton, whose successful experience at the Samaritan Hospital, and whose predilections for operation at that institution, might easily give him a bias in the opposite direction, has very definitely arrived at the conclusion that the minute observance of Mr. Lister's directions and antiseptic method afford so much immunity from surrounding influences of hospital infection, as to render the patient and operator almost independent of such surroundings. This also is the opinion at which Dr. Marion Sims has arrived; and he has, we believe, in a communication which he has addressed to an American journal descriptive of his recent observations in London, formally recorded his conclusions to that effect, and expressed himself enthusiastically as to the merits of a method which robs the most serious of surgical procedures of all extraneous perils to life, and enables every well-skilled surgeon to employ it, without the necessity of creating a special hospital arrangement for the purpose.

#### PROPOSED TESTIMONIAL TO PROFESSOR BALFOUR OF EDINBURGH.

A MEETING of Edinburgh graduates was held at the house of Dr. Duckworth on the 15th inst. to promote the above object in London and elsewhere. It was announced by Dr. MacIntosh, F.R.S., of Murthly, that about £250 had been already collected from friends and former pupils of Dr. Balfour. A most excellent portrait of the Professor has been painted by Sir Daniel Macnee, President of the Royal Scottish Academy, and this is to be presented to the Senate Hall or Library of the University. It is desired to produce a *replica* of this, from the same hand, as a gift to Dr. Balfour's family, and additional subscriptions for these purposes are now sought. A London Committee was formed consisting of the following members: the Rt. Hon. Lyon Playfair, C.B., M.P.; Dr. Murchison, F.R.S.; Dr. Crichton Browne, F.R.S.E.; Sir Joseph Fayrer, K.C.S.I.; Mr. E. Chisholm Batten, M.A.; Dr. Allen Thomson, F.R.S.; Dr. Sieveking; Dr. Farquharson; Professor Huxley, Sec.R.S.; Mr. Joseph Lister, F.R.S.; Dr. Wm. Playfair; Dr. Priestley; Dr. Ferrier, F.R.S.; Dr. Bardon Sanderson, F.R.S.; Dr. Duckworth; Dr. Lauder Brunton, F.R.S.; Dr. T. Spencer Cobbold, F.R.S.; Dr. Laidlaw Purves; Dr. Potter; Mr. R. Davy; Dr. Glover; Dr. George Harley, F.R.S.; Dr. A. Hughes Bennett; Mr. Henry Rutherford; Mr. Caruthers, F.R.S.; Dr. H. S. Wilson; Dr. J. Watt Black. Various secretaries were nominated in the provincial towns, in India, and the Colonies. It is believed that the scheme only requires to be known to the numerous pupils of the zealous and beloved Professor of Botany, scattered all over the world, to ensure a ready response. It was thought fitting thus to mark the kindly services of Dr. Balfour, who had acted as Dean of the Medical Faculty for more than thirty years, and had recently retired from that office. Subscriptions will be received by any member of the Committee, or may be sent direct to David Smith, Esq., Treasurer of the Royal Society of Edinburgh.

#### DIPHTHERIA AT UPPER CLAPTON.

THE inhabitants of Upper Clapton have been considerably alarmed by an outbreak of diphtheria, which they attribute to an accumulation of house-refuse on the hill-side at Clapton Common. This opinion is, to a certain extent, supported by certificates from several local medical practitioners and by Dr. Tidy, who, in this case, expresses himself in a manner which is diametrically opposed to the statement he made respecting a dust-yard in his own district. Dr. Tripe, the medical officer of health, however, says that the accumulation was in no way connected with the outbreak, as the disease did not appear in the houses nearest to the accumulation (which is above an eighth of a mile from

the nearest house), but from the effects of sewer-gas, which had obtained an entrance to the houses where the disease occurred. He also bases his opinion partly on the fact that whilst in above 150 houses in which the drainage arrangements were good only 1 case occurred, no less than 13 cases had happened in 11 houses where they were defective. It also appears that the heap has been sown with oats, and the deposit of dust has been stopped. The question of the removal of house-refuse is one attended with much difficulty in London; but there can be no doubt that the best course for the vestries and district boards to adopt is its removal, by barge or railway, into the country, where what is refuse here becomes a valuable article of commerce, either for brickmaking or for manuring heavy land.

#### MEDICAL ETIQUETTE.

DR. ABRATH of Sunderland considers himself aggrieved by the comment which we made in the JOURNAL of April 6th, upon an advertisement which appeared in the *Sunderland Echo* of April 1st, and which we considered contrary to notions of professional propriety. We direct attention to his letter explaining his reasons for that advertisement, which we publish on page 589, together with a reprint of the advertisement itself. We regret that, after re-reading the advertisement, and taking into consideration the circumstances stated by Dr. Abrath, we are unable to form any other opinion than that the advertisement in question is not consonant with the generally accepted notions of professional propriety among the medical profession in this country; and we say this without any reference to Dr. Abrath's views or acts, but as upholding the high professional standard which this Association has always desired to maintain. If Dr. Abrath think that our views on the subject differ in any way from those of the Association or the profession generally, he can easily satisfy himself by referring the subject for the opinion of the Council of the Branch of the Association in his district, or by asking the opinion of the Council of the Apothecaries' Society; and we shall be very happy to publish such opinion; or we shall be happy to assist him to obtain a further opinion from any source of authority in the medical profession which he may prefer.

#### THE OPHTHALMIC SURGEONCY AT ST. THOMAS'S HOSPITAL.

MR. NETTLESHIP has been elected Ophthalmic Surgeon to St. Thomas's Hospital, in the vacancy created by the resignation of Mr. Liebreich, who has been appointed Consulting Ophthalmic Surgeon to the hospital. Mr. Nettleship had the advantage of receiving the unanimous support of the medical staff, who had all concurred in considering that he had higher claims to the appointment than any other of the candidates. Strange to say, however, a movement was set on foot to subvert the just influence of the medical staff with the governors in deciding on the professional merits of the candidates; and the result of a very active canvass was such as make it likely that a candidate, whose superior qualifications had secured the unanimous suffrages of those best able to judge, would be set aside for one whose claims had been considered of a less convincing order. The medical staff were taken by surprise at so unusual a canvass as was instituted, and it was only by a casting vote of the governors that Mr. Nettleship's election was secured. St. Thomas's Hospital may be congratulated on having secured an officer of well known accomplishments and high professional promise; and the Governors may be regarded as fortunate in having escaped committing themselves to a proceeding, which would have savoured strongly of ingratitude and incompetency for the trust assigned to them.

#### MANCHESTER ROYAL INFIRMARY.

ON Monday last, a special meeting of the General Board of Management of this infirmary was convened to consider certain proposals for alterations in the system of management. Among other things, it was proposed that the rule referring to the qualifications of physicians to the infirmary should set forth that every candidate for the office of physician should be a Fellow or Member of the Royal College of Physicians in London, and should have a diploma from some university requiring

examination for its degrees, together with satisfactory attestations of having studied in some well reputed school or schools of medicine during four years, at which at least one year shall have been spent in the university where he graduated, except in the case of the University of London, where residence is not required. A memorial from Dr. Radford, Dr. Lloyd Roberts, and several other medical gentlemen, was read, stating that the condition requiring one year's residence at an university would exclude a large number of English students who prosecuted their studies at the great medical schools of London and the provinces, and give an unfair advantage to Scotch and Irish students. The memorialists, therefore, urged the board to allow the old rule to remain in force. By the casting vote of the Chairman, it was resolved that the rule should remain as quoted on the revised list, which must be, however, submitted to the trustees in general meeting on the 26th instant. The resolution, we are informed, was passed by the lay board in opposition to the opinion of a majority of the Medical Committee of the Infirmary, expressed at a full meeting held on the 6th instant. Such a clause is, as our correspondent points out, a move in a backward direction. The lay board, by the terms of the rule, are not satisfied with an university degree and the Fellowship or Membership of the Royal College of Physicians of London, such as would be required at any London hospital, but seek to make it imperative that the candidate should have resided one year at the university where he took his degree: a sort of special educational requirement which trenches upon the province of the General Medical Council of Education. We know no precedent for such a resolution, and do not understand what can render it necessary in this city more than elsewhere.

#### THE HUNTERIAN SOCIETY.

AT the meeting of the Hunterian Society, which will be held in the London Institution, Finsbury Circus, on Wednesday, April 24th, Dr. B. W. Richardson, F.R.S., will read a paper "On the Practice of Total Abstinence from Alcohol in Health and Disease". We are requested to state that the President and Council desire that every member of the profession interested in the subject may be present to hear the paper and join in the discussion.

### SCOTLAND.

OWING to the prevalence of measles in the town of Alloa, the public schools have been ordered to be closed for two weeks.

LAST week, Dr. Haldane of Braemar was presented, on the occasion of his leaving to settle at the Bridge of Allan, with a time-piece and a silver service, in recognition of the respect, affection, and esteem entertained for him by his many friends in Braemar.

DR. MACKENZIE, a physician who has been for many years resident in Kelso, where he was held in high esteem for his professional skill and personal character, died in that town on Saturday, at the age of fifty-nine. He had held for a considerable period the appointment of Physician to the Kelso Dispensary, and was a prominent member of the Border Medical Society.

AT a recent meeting of the Edinburgh University Court, it was resolved, *inter alia*, to authorise the opening of a Class of Practical Materia Medica in the University; the course to consist of not less than fifty hours' instruction: the fee for the course was fixed at three guineas. It was further resolved, to submit to Her Majesty in Council, for approval, an alteration of Ordinance No. 5, Section v. with a view to constituting attendance on this class a way of obtaining the instruction in the compounding and dispensing of drugs which is required for graduation in Medicine in the University.

#### GLASGOW: THE MILK QUESTION.

IN the minutes of the Glasgow Health Committee, submitted to a

meeting of the Town Council on Monday last, it was stated that Dr. Russell, Medical Officer of Health, reported that, according to instructions, he had gone to London in reference to legislation on the milk question. He obtained an interview with the Duke of Richmond and Gordon, and submitted the suggestion as to the dairy and cow-shed clauses in the Cattle Diseases (Animals) Bill. His Grace stated that it was a mistake to suppose that the words "infection or contamination" in these clauses referred to the diseases of human beings. The whole Bill had reference only to the diseases of animals. He thought the subject was one for the Local Government Board. Dr. Russell saw the Medical Officer and Counsel to the Board, but got no encouragement to hope that any Government measure would be brought in. At a subsequent meeting with the Lord Advocate, at which several members of the Health Committee were present, a similar opinion was expressed, although his Lordship seemed personally favourable. Mr. Anderson, M.P., was then seen, and expressed his readiness to introduce a short measure on the subject. It was subsequently stated that Mr. Anderson had drafted a short Bill, but it was probably too late to get anything done this session. With reference to milk-dairies in Glasgow, it was stated, in the Sanitary Officer's report, that fifty-three places for selling milk had been inspected, when it was found that, in forty-four of these, other articles were sold along with the milk, and the keepers and their families lived in the back premises. Nine were found arranged for the sale of milk only, without any sleeping accommodation. The whole appeared clean and in good order.

## IRELAND.

DR. BALDWIN, Medical Officer of Kilmeadan Dispensary District, died suddenly at Portlaw on the 30th ultimo, being found dead in his bed. The deceased had been in delicate health for some time, but a fatal termination was quite unexpected.

### TAKING CARE OF A PUMP.

DR. RICHARD RYAN of Carrigtwohill, at a recent meeting of the Guardians of the Middleton Union, reported that the water supplied by the public pump in the village was unfit for use. In consequence of the sanitary arrangements, the water was impregnated with fetid gases and other deleterious ingredients, at once poisonous in themselves and rendering the water totally unfit for drinking purposes. He suggested that steps should be taken to close the present well, and that another be sunk in the village, at an available site, easy of access to the inhabitants, and which would not contain facilities for contaminations. The guardians seemed disinclined to adopt this arrangement, and appointed a caretaker to look after the pump, which, it was considered, would abate the nuisances complained of. The expedient seems comical, and will hardly avail to prevent disease from occurring.

### APPOINTMENTS.

At a meeting, held on the 25th ultimo, Dr. Brennan was unanimously appointed Medical Officer to the Kiltormer Dispensary District of the Ballinasloe Union: emoluments, £127 *per annum*, with registration and vaccination fees. Dr. Jefferson has been appointed to the Aghalee Dispensary District, Lurgan Union, at a salary of £116 yearly, with registration, etc., fees. On the 14th ultimo, Dr. Taaffe was elected to the Ardahan Dispensary, Gort Union, at a yearly salary of £150, with the usual extras. The vacancy in Carney Dispensary, Sligo Union, has been filled up by the selection of Dr. O'Neill, the emoluments amounting to £140 *per annum*, with registration and vaccination fees.

### LIMERICK LUNATIC ASYLUM.

At a recent meeting of the board, the report of Dr. Nugent, Inspector of Asylums, was read. It spoke in high terms of the condition of the institution generally, and stated that its accommodation would be greatly improved by the addition of the one hundred and forty beds the new establishment would give.

### RATHDOWN UNION: SMALL-POX.

A REPORT from Drs. Darby and Mayne was received by the guardians of this union last week, suggesting that the entire fever hospital should be devoted to small-pox patients: a recommendation which has been objected to by the Local Government Board, who considered that special sheds should be erected for that purpose. On a division, it was resolved that sheds should be erected as proposed, the Chairman giving a casting vote in favour of the plan.

### OUTBREAKS OF MEASLES.

At Cappamore, Limerick, a serious epidemic of this disease has occurred. Dr. Keys, medical officer of the district, lately attended one hundred and fifty dispensary patients and sixty private patients in the village and its vicinity. The deaths since the outbreak have already amounted to twenty-four, and the disease has been of a malignant type in most cases among the poor. The disease, which was introduced from Tipperary, has been much influenced by the ill-ventilated houses, the extreme poverty of the poor, the bad sewerage of the village, and want of cleanliness of the people. The improvement of the drainage has been urged upon the Limerick Rural Sanitary Board by the Local Government Board, and a motion will be considered this week for the effective drainage of the village concerned. At a meeting of the Wexford Board of Guardians last week, a letter was received from the Local Government Board, calling their attention to the fact of there being over seventy children affected with measles transferred to the Fever Hospital, Wexford, and requesting a report from the medical officer as to the epidemic, and the sufficiency of the accommodation available for the treatment of such a large number of cases. Dr. Crean, the medical officer, reported that the children attacked had been transferred to the Fever Hospital sheds; that the disease was of a mild type; and that the greater number of those attacked were now convalescent.

### SMALL-POX IN BELFAST.

At a meeting of the guardians of the Belfast Workhouse last week, Dr. Seaton Reid, in reply to a communication from the Local Government Board, stated that, as the accommodation for small-pox patients in hospital was now more than sufficient for all who were applying, he would suggest that, for the present, the shed on the Twin Islands should be used as a quarantine-ward, to which the healthy members of a family could be transferred when those ill with small-pox had been sent to the hospital. This would give an additional ward in the hospital for small-pox patients, should the numbers increase. Dr. Reid, having found that some patients who had been in hospital with fever, took small-pox after leaving it, investigated the matter, and ascertained that there was a hole in the wall which separated the drying-loft for the fever-patients' clothes from that in which the small-pox clothes were dried; and, therefore, believed it was possible that the clothing for fever-patients may in this way have become infected. For the week ending the 6th instant, there were forty-four cases of small-pox under treatment in the Union Hospital, eight fresh cases having been admitted during the week.

### THE DEATH-RATE OF DUBLIN.

A SPECIALLY convened meeting of the Dublin Sanitary Association was held last week, to consider what steps should be taken in reference to the present high death-rate in this city. The Association were anxious that a public inquiry should be held into the cause of the continued excessive mortality, and hoped that the Public Health Committee of the Corporation would have joined them in seeking an official investigation. A misunderstanding, which, however, was in great part explained away at the meeting, unfortunately arose between the two bodies; the Corporation Committee finally declining to be parties to seeking an inquiry, contending that, as the causes of the high death-rate were well known, the proposal was unnecessary. These causes, as explained by the Superintendent Medical Officer of Health, are: The

wretched condition of the tenement-houses in Dublin, the poverty of the population, overcrowding, and the spread of intemperance. The Sanitary Association, in a report on the subject, assigned several additional causes, viz., bad drainage of the city, the defective scavenging of its streets, the filth of the Corporation manure depôts, and the condition of the slaughter-houses. Several suggestions, made by the Sanitary Association, with a view to remedy these crying evils—the existence of which could not be denied—were characterised as Utopian and absurd—possible, it might be, in Dr. Richardson's Hygiea, but quite out of the question in a crowded city like Dublin. The meeting was well attended, and several interesting speeches on the sanitary condition of Dublin—notably one by Surgeon-General Crawford, the principal Medical Officer of the Army Medical Department in Ireland—were made. It was finally resolved: "That the Executive Committee be directed to communicate with the Chief Secretary for Ireland, requesting him to receive a deputation from the Association, to lay before him a statement of their reasons for believing a public inquiry would be necessary." It is to be regretted that in Ireland there are no properly qualified inspectors under the Local Government Board, as in England, by whom such an inquiry as asked for could be satisfactorily conducted.

#### SMALL-POX IN LIMERICK.

At a meeting of the Corporation Sanitary Board last week, a report was read from Dr. Meehan, recommending that the houses of parties having small-pox patients should be fumigated, the bedding and clothes washed, and the house whitewashed. Dr. Barry, in reply to one of the guardians, stated that washing the clothing of small-pox patients was inadequate, and he considered that articles of this nature should be disinfected. There were eleven cases under treatment in the union hospital last week, and the convalescent patients from fever became so alarmed that they suddenly decamped from the workhouse. The Board of Guardians have determined to rent a portion of St. John's Hospital for the accommodation of small-pox patients, owing to a recent communication from the Local Government Board, who pointed out that there was not proper provision outside the house for this class of patients, should an epidemic occur.

#### NEWTOWARDS BOARD OF GUARDIANS.

At a meeting of this board last week, their attention was directed to a recent report of Dr. S. Stewart, the sanitary officer for Donaghadee, to the Local Government Board, stating that he had several times brought the notice of the guardians to the sanitary condition of the town, but that nothing had been done to remedy the evils complained of. At the same meeting, Dr. Reuben Bolton, the Bangor sanitary officer, reported that three deaths had recently occurred in the town from diphtheria, which it was probable arose from the defective sewerage, which appears to be inefficient, inasmuch as the works are limited to but a portion of the principal thoroughfares, situated at one side of the street in each case, and allowed to discharge their contents into the sea at an unsuitable spot without the intervention of any tank to retain the solid portion of the sewage matter. Both these reports were referred to the dispensary committees of the respective localities for their consideration.

#### DOWNPATRICK WATER-SUPPLY.

On the 9th instant, Dr. Roughan, Local Government Board Inspector, held an inquiry in the Court-house, Downpatrick, into the proposed scheme for supplying this town with water. Several medical gentlemen were examined, and agreed in stating that the present supply of water was inadequate; whilst the evidence of Dr. Cameron as regarded the quality of the water proposed to be introduced was to the effect that it was a very fair water for drinking and domestic purposes, and that, on examination of the wells and fountains in Downpatrick, he had found them all to be of an exceptionally bad quality. It is expected that the proposed waterworks can be carried out for about £13,000.

## THE MEDICAL ACTS AMENDMENT BILL.

*To the Members of the British Medical Association.*

THE Medical Reform Committee desires to impress on the members of the Association and on the Secretaries of Branches the importance of urging the preparation of petitions to the House of Lords, in accordance with the form issued by the Committee.

The petitions must be written on *one side* of a sheet of paper, and signed on the *same side* of the same sheet by at least one person.

Any further number of names may be subsequently added by joining additional sheets.

Members of the Association are requested to use their influence with such registered medical men as are not members to support the Association.

EDWARD WATERS,

Chairman of the Medical Reform Committee.

Committee of Council Room, April 17th, 1878.

## ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary meeting was held on the 15th instant.

Dr. Christian Gottfried Bämler was admitted a Fellow.

Licences to practise Physic were granted to several gentlemen.

A communication on the Distribution and Causation of Leprosy in the Bombay Presidency from the India Office was read.

The sum of one hundred guineas was voted towards a Statue of Harvey, to be erected at Folkestone, his birthplace. The College resolved to hold a National Banquet in honour of Harvey at the College during the present season, this being the three hundredth year since Harvey's birth.

A Committee was appointed to make the necessary preparations.

The Treasurer having stated that the new edition of the *College Roll* was nearly completed, power was given to the Roll Committee to take the necessary steps for its publication.

The President then addressed the Fellows, reviewing the principal events of the past year, and resigning his office. A ballot was taken; and James Risdon Bennett, M.D., F.R.S., was unanimously re-elected President for the ensuing year.

Thanks were voted to the President for his address.

The President returned thanks on his re-election.

## THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following requisition was presented to Mr. Lund on Tuesday, April 16th.

*To Edward Lund, Esq., F.R.C.S., &c.*

Dear Sir,—We, the undersigned Fellows of the Royal College of Surgeons, respectfully hope that you will offer yourself as a candidate for the forthcoming vacancy in the Council of College, feeling a just confidence that your acknowledged eminence as a surgeon, and wide popularity both in London and the provinces will insure a successful issue to the contest.—We are, dear sir, yours faithfully, &c.

[The requisition is not only very numerous, but very influentially, signed, including many well known London names as well as provincial, to the number of upwards of 350. Pressure of space, however, prevents us from appending the list of names.]

*Mr. Lund's Reply.*

Gentlemen,—The fact that more than three hundred Fellows have signed the requisition presented to me to-day asking me to consent to be nominated as a candidate at the next election of members of the Council of the Royal College of Surgeons of England leaves me no alternative but to accept with many thanks the compliment thus paid to me, and to accede to the request contained.

This request has been tendered so much earlier than I had expected that I fear, in your anxiety to carry out speedily the wishes of my friends, you may seem to have overlooked the names of other Fellows of our College whose claims to such a post of honourable trust are quite equal to my own; but I hope the good sense of the constituency to whom I have to appeal will not permit my cause to suffer through any excess of zeal in its supporters.—Very truly yours,

EDWARD LUND.

## THE HARVEY TERCENTENARY MEMORIAL FUND.

THE amount subscribed now exceeds £1,250. Amongst the contributions of the past week, are one hundred guineas from the Royal College of Physicians of London. We are desired to state that further subscriptions are greatly needed, and again to request the members of the profession who have not hitherto contributed to this object to kindly send their donations at once to either of the hon. treasurers (Sir George Burrows, Bart., or Mr. Prescott Hewett), or to either of the hon. secretaries (Mr. George Eastes, M.B., 69, Connaught Street, Hyde Park Square, London, W.; or Mr. W. G. S. Harrison, B.A., Town Clerk, Folkestone), or to pay them into the account of the Harvey Tercentenary Memorial Fund, at the Western Branch of the Bank of England, Burlington Gardens, London, W. Subscriptions from five shillings upwards will be very acceptable.

## ASSOCIATION INTELLIGENCE.

## BATH AND BRISTOL BRANCH.

THE fifth ordinary meeting of the Session will be held at the York House, Bath, on Thursday, April 25th, at 7.15 P.M.; HENRY MARSHALL, M.D., President.

R. S. FOWLER, } *Honorary Secretaries.*  
E. C. BOARD, }

Bath, April 1st, 1878.

## NORTH OF ENGLAND BRANCH.

THE spring meeting of this Branch will be held in the Board Room of the Guardians, at Hexham, on Thursday, April 25th, at 2 o'clock P.M.

The following papers, etc., have been promised.

1. Drs. Stainthorpe and Farmer: Case of Aortic Aneurism in a boy aged 13.
2. Drs. Stainthorpe and Farmer: Case of Contracted Knee-Joint, recently operated on by division of the Tendons and Forcible Extension.
3. Dr. Byrom Bramwell: On the Differential Diagnosis of Aortic Aneurisms and other Intrathoracic Tumours, with cases and specimens.
4. Dr. E. C. Anderson: On Leucine and Tyrosine, and their Diagnostic Value in Disease, with cases.
5. Dr. James Murphy: Exhibition of Tarnier's Obstetric Forceps.
6. Dr. James Murphy: On Puerperal Convulsions.
7. Dr. Philipson: Notes of a Case of Hæmaturia.
8. Dr. J. C. Murray: Case of Difficult Instrumental Labour from Deformed Pelvis.
9. Dr. M. McW. Bradley: *Post Partum* Hæmorrhage; with notes of three cases successfully treated by compression of the Abdominal Aorta.
10. Dr. Eastwood: Medical Reform and a Petition to Parliament.

Dinner at the White Hart Hotel at 4.30 P.M.; charge six shillings, exclusive of wine.

G. H. PHILIPSON, M.D., *Honorary Secretary.*  
Newcastle-upon-Tyne, April 2nd, 1878.

## CORRESPONDENCE.

## THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

SIR,—I request the favour of an insertion in your JOURNAL of a copy of a letter, which I have addressed to Mr. Bradley, on the subject of Mr. Lund's candidature for election into the Council of the College of Surgeons.—I am, sir, your obedient servant, T. B. CURLING.

39, Grosvenor Street, Grosvenor Square, W., April 13th, 1878.

"39, Grosvenor Street, Grosvenor Square, W., April 13th, 1878.

"Dear Sir,—I regret that I am unable to sign the paper you have sent me, inviting Mr. Lund to become a candidate, at the next election, to the Council of the College of Surgeons. Mr. Lund's position as a surgeon, and his contributions to surgical literature, I cordially agree with you, entitle him to the confidence of the profession; but they do not give him a claim to election on the College Council in preference to many of his seniors in the Fellowship, amongst whom I may name Mr. Lister, Sir Henry Thompson, Mr. Callender, Mr. Hulke, Mr. Heath, Mr. Durham, and Mr. Hutchinson.

"There are already three Provincial Fellows on the Council, and, if the numbers be increased, there may be difficulty in getting the busi-

ness of the College transacted. Members of the Council residing at a distance from London are not usually elected on important committees, from a desire not to put them to the serious inconvenience of attendance; and they are practically ineligible for the higher offices of President and Vice-President, who are expected to attend all committees.

"Even if there were not several Fellows from the provinces on the Council, I should demur altogether to the reason you give for Mr. Lund's election as a representative of the provincial Fellows. The Council know nothing of class interests. The interests of the provincial Fellows are equally the interests of the metropolitan.—I am, dear sir, yours faithfully,

"S. M. Bradley, Esq."

"T. B. CURLING."

## MEDICAL REFORM.

SIR,—I have just received a circular inviting me, at the instance of the Medical Reform Committee of the British Medical Association, to enrol myself as an individual atom, or (say)  $\frac{1}{200000}$ th part, in a *plébiscite* of the whole profession, as regards two important questions to be answered by a simple "Yes" or "No". I cannot give such an answer, and I wish to explain to you the reason. In doing so, although I do not affect to speak for more than one member of a large body, it may be that I shall be giving expression to opinions also entertained by others.

For the Medical Reform Committee, individually and collectively, I feel, personally, nothing but entire respect. Most of the members of it are my friends, some of them very old friends. But I venture to doubt whether the principle of the *plébiscite*, as thus introduced by them into medical politics, is a sound one. We all know that when Napoleon some years ago, under the Second Empire, demanded of the French people the famous "Oui", or "Non", the issue was already prejudged in his favour. We all know, also, what that same French people think now-a-days of the claims of the "man of Sedan". It may be, that a *plébiscite* without reasons, and promoted by the Medical Reform Committee upon a prejudged issue, may be equally conclusive as to the real opinion of the medical profession.

A prejudged issue? Yes; for the letter of the seven members of Committee, enclosed along with the voting paper, declares that "the action of the British Medical Association and of the profession is *imperatively required* to frustrate the passing of a Medical Bill which does not embody the principles, etc."; and it calls upon every one of us to petition the House of Lords against "any Bill which does not embody these great principles". A form of petition to this effect, ready made for use, and with full directions, is enclosed along with the voting paper and this general order from head-quarters. Now, that is what I call a somewhat Napoleonic proceeding, no doubt in a very modified degree as compared with the original; let us call it a very mild kind of benevolent despotism on the part of our Medical Reform Committee.

I will now give you my answers to the two questions—not in the simple form proposed of "Yes" and "No"—yet briefly, and without too much detailed argument.

1. Are you of opinion that the medical profession should be directly represented in the General Medical Council? *Answer*—Yes; provided a fitting machinery can be devised for so complicated and difficult an operation as ascertaining, and finally giving effect to, the real mind of the whole profession upon the claims of individuals; but certainly *not*, if you, Mr. Editor, and the Medical Reform Committee, or any other committee, or committees, of the British Medical Association, are to be constituted the official wire-pullers, or promoters, of a vote done, like this one, in the form of a *plébiscite*. And I need hardly say to you that I mean nothing offensive, or even disrespectful, to any of you by this declaration. What I mean is simply that the medical profession, apart from its ancient and more or less organised corporations, is at present an almost inorganised and incoherent mass of opinion, which can only be organised through some kind of deliberative assembly, and not through a chance got in a hurry, say for half an hour at each annual meeting of the British Medical Association, for expressing itself in a kind of casual and make-believe fashion on such important questions as are here submitted to us at the instance of the Medical Reform Committee. Those who were present last year at Manchester know what kind of discussion takes place, and who represent "the profession", when nine-tenths of the Association have gone off in search of amusement on a fine afternoon, caring nothing about politics. Dr. Waters, in particular, will, I think, probably agree with me that "the profession" does not always appear to advantage in such political discussion, when, like every other fortuitous concourse of atoms, we are blown hither and thither, while perhaps a dozen or two of us make speeches and pass resolutions, in the name of the British Medical Association.

2. Are you of opinion that the establishment of a conjoint board for the granting of licences to practise all branches of the profession should be made compulsory in each of the three divisions of the kingdom? *Answer*—Certainly not; for although the question of conjoint boards, as above, has been before us in Scotland now for these eight or nine years, I believe it is perfectly safe to affirm that the more we look at it the less we like it. Of course it will be said that this is a mere corporation and university prejudice on the part of the northern division of the kingdom. Be it so; it is not my purpose at present to argue that point. But this I will say, that, among corporations, the Royal College of Surgeons of Edinburgh is distinguished by nearly a whole century of disinterested effort on behalf of the general practitioner, and its diploma has from first to last been granted only after an education much more complete than that required by any single corporation in England. I will not speak of the Universities of Scotland, though of three of them, at least, it may be said that during the last twenty or twenty-five years they have done more of practical educational work (and I believe it will be admitted of a constantly improving quality) for larger numbers of the medical profession than any other institution in the country. To carry by sheer force of numbers blindly led a "principle" opposed to the deliberate conviction of bodies like these is not, in my opinion, a justifiable use of a *plébiscite*. And therefore, without in the meantime giving you my own ultimate conclusions either as to the Duke of Richmond's Bill, or the "great principles" of the Medical Reform Committee, I venture to think that their mode of action at present is to be deprecated, and does not afford a strikingly good example of the direct representation of the medical profession.—I am, sir, yours, etc., W. T. GAIRDNER.

Glasgow, April 15th, 1878.

## MEDICO-PARLIAMENTARY.

HOUSE OF LORDS—Monday, March 15th, 1878.

*Medical Act (1858) Amendment Bill.*—On the motion for the second reading of this Bill, the Marquis of RIPON said the measure dealt with the important question of how in future persons were to obtain a licence to practise surgery and medicine in the United Kingdom. At the present time, there were in England, Ireland, and Scotland nineteen different bodies, the diplomas of each of which entitled the holder to have his name placed on the *Medical Register*. It was scarcely necessary to point out the inevitable effect of allowing distinct bodies to confer a title to practise. It was that some of those bodies attempted to underbid the others as to the terms on which they granted their licence. Consequently, the public had not the necessary security that the holder of a licence had the minimum qualification which ought to entitle a man to practise as a surgeon or a physician. It was felt very generally that there ought to be but one Examining Board, or that at most there ought to be only one for each of the three parts of the United Kingdom, through which admission to the practice of medicine could be legally obtained. Since 1858, when the Medical Council Bill was passed, there had been almost continuous, but unsuccessful, attempts to establish what was known as the conjoint scheme. As the Bill of his noble friend was merely permissive in that respect, it would leave the matter of a conjoint scheme where it had been for the last twenty years. His noble friend had expressed a hope that, before the Bill was before both Houses, such a scheme would have been established for England; but he had held out no hope that such a scheme would by that time have been established for either Ireland or Scotland. He only went the length of saying that, when conjoint schemes were framed for those countries, they would, under the Bill, when an Act of Parliament, obtain legal force. His noble friend must by this time be aware that the College of Surgeons of London, the College of Physicians of London, the Syndicate of the University of Cambridge, the representative of the University of Oxford on the Medical Council, and the representative of the University of London, had all in discussing the Bill, pronounced in favour of a conjoint scheme as compulsory under this measure. This was not the case of old corporations wishing to uphold their own privileges, but that of examining bodies who were ready to make a sacrifice of their own independence in the matter of licences to practise and to have a conjoint scheme, provided they were not exposed to the competition of small bodies standing outside that scheme, and having power to grant such licences. His noble friend had, no doubt, seen in *The Times* of Saturday, a report of a meeting of the Medical Council, held on the previous day, at which a resolution in favour of a compulsory provision for a conjoint scheme in the Bill before their Lordships was proposed by Professor Humphry, seconded by Sir James

Pager, and carried by a large majority. The resolution declared that nothing short of the compulsory establishment of a joint examining Board in each of the three portions of the United Kingdom could be deemed satisfactory. The British Medical Association, a body numbering, he believed, 7,000 members, strongly objected to the Bill, because it was permissive in respect of a conjoint scheme, and on another ground. As in 1870, the British Medical Association were strong enough to procure the rejection of his Bill, which was compulsory, he thought his noble friend had every reason to fear that his measure might not meet with a better fate. He did not propose to challenge the opinion of the House on the second reading. As, probably the resolution arrived at by the Medical Council was not in the hands of his noble friend till Saturday, he should not ask him for a positive opinion at the present moment; but he did hope that his noble friend would seriously consider the question between that stage and the committee on the Bill, and would see his way to make it compulsory in respect of a conjoint scheme. His noble friend had a great opportunity of settling an important question, and he hoped he would not avail himself of a political majority to pass a Bill which would be satisfactory neither to the profession nor to the public.—The Duke of RICHMOND and GORDON was glad that his noble friend was not going to challenge the second reading, because if he did so, and he were successful, as he seemed to think might be the case, he would indefinitely postpone the settlement of a question which they all wished to see settled. The history of the Bill was this. In the month of May of last year, he received from the General Medical Council, through its President—of whom one could hardly say too much either from a professional point of view or in reference to the manner in which he discharged his duties as President of that body—a memorial in which he was asked to deal with five points: first, the foreign and colonial degrees; second, the registration of the medical qualifications of women; third, the appropriation of penalties under the Act; fourth, midwives; fifth, the lunacy laws. It was a remarkable fact that the conjoint scheme was not included in that memorial of the Medical Council. He did not say that Council was not alive to it; but certainly the question was not brought under the notice of the Medical Council. He was quite willing to admit that if there were an uniform and satisfactory test, more especially with this Bill, it would be possible to deal with unqualified practitioners in a more stringent manner than they could now be dealt with; and he thought it possible that the best mode of having such a test was for a conjoint scheme. His noble friend when filling the office which he had now the honour to occupy had endeavoured to legislate on the subject, and his experience in 1870 had led him to very candidly acknowledge that the task was no easy one. There were a number of interests which required considerable attention in order that a means of reconciling them one with the other might be found. And it was by no means clear that success in that direction was attainable. In England, the difficulty in respect of a conjoint scheme was not so great. The Universities of Oxford and Cambridge did not object to such a scheme. In Ireland, again, as all the medical bodies were more or less centred in Dublin, he did not imagine there would be any great difficulty. In Scotland, however, the case was otherwise. There were the College of Surgeons, the College of Physicians, and the Faculty of Physicians in Edinburgh; the Universities of Edinburgh, Glasgow, Aberdeen, and St. Andrew's—all of which would be very much affected by a conjoint scheme. The fact was—so desirous had he been of, if possible, coming to some conclusion which would enable him to legislate on the difficult subject—that he had adopted the alternative his noble friend condemned very severely, and made the provision as to a conjoint scheme permissive for the three parts of the United Kingdom; and, in order to meet the objection to the provision being only permissive, he had raised the qualification of medical practitioners by providing that no person could be placed on the *Register* of the Medical Council who did not possess two qualifications—one in surgery, and the other in medicine. He was quite ready to admit that this was not the best solution of the difficulty, but it was a step in the right direction, supposing that it was not possible to insert in the Bill a compulsory clause for the three parts of the United Kingdom. He was aware of the objections taken to the Bill by the medical bodies to which his noble friend had referred, and he was far from saying that there ought not to be a conjoint board. He thought it would be dishonest of him to say that it would not be an advantage to the country; but it was not always easy to carry out by Act of Parliament what one thought desirable. The clause in the Act referring to the medical examination of women was inserted to cure a technical defect in Mr. Russell Gurney's Act, and would not render it more difficult for women to enter the medical profession, except inasmuch as it raised the standard of

qualification for registration by requiring a double qualification from all persons who sought to be put on the Register.

The Bill was then read a second time.

#### HOUSE OF COMMONS.—Thursday, April 11th, 1878.

*The Cruelty to Animals Act.*—Mr. HOLIER asked the Secretary of State for the Home Department, with reference to the return of licences granted under the Cruelty to Animals Act, 1876, for which an address to the Crown was ordered on the 19th ult., whether he was willing to include in the return the number of licences cancelled, the reasons for which they had been cancelled, and the names of the inspectors employed under the Act; and whether he still objected to publish the names of the persons licensed. He also wished to ask whether a return would be given in reference to Ireland?—Mr. CROSS said no licences had been cancelled on account of misconduct by their holders. There could be no objection to the return asked for; but he could not promise the names of the persons to whom licences had been granted. He had no jurisdiction as far as Ireland was concerned; but he had no doubt that his right honourable friend the Secretary to the Lord Lieutenant would assent to a return as far as that country was concerned, if it were moved for.

*The Case of the Rev. Mr. Dolwell.*—Dr. KENFALY asked the Secretary of State for the Home Department whether he would explain to the House why, after the reports made to him by Dr. Forbes Winslow, in consultation with Mr. Gibson and Dr. Winn, which declared the perfect sanity of the Rev. Mr. Dolwell, now in Newgate for a common assault, he still detained that gentleman in custody as a criminal lunatic, to be confined during Her Majesty's pleasure, and whether he would recommend his release without further delay.—Mr. CROSS: I think that the terms of the honourable member's question might lead some honourable members to suppose that I had called for a report from the gentlemen named; but that is certainly very far from being the fact, I merely having received certain letters from them in reference to the case in question. I have this morning received a letter from two of these gentlemen, stating that notice of this question had been placed upon the paper without their sanction and against their wish. In reply to the question of the honourable member, I have to state that it has been found by the verdict of a jury that this unfortunate gentleman committed the act constituting the offence for which he was indicted when insane; and he has, therefore, in accordance with the usual practice, been sent to the Criminal Lunatic Asylum at Broadmoor. In accordance with the invariable practice of my predecessors, I shall allow him to remain there until I am advised by the proper authorities that it will be safe to the public and to himself to release him.

## MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Licentiates on April 15th, 1878.

Bartlett, Felix Paul, 5, Albert Street, N.W.  
Birt, Ernie C. County Asylum, Shrewsbury  
Davis, George, 11, Avenue, Blackheath, S.E.  
Dumbleton, Edgar Hunt, 41, Commercial Street, E.  
Ellis, William Ashton, 59, Sloane Street, S.W.  
Gatdale, Ernest Langwith Gompertz, 8, Chase, Clapham Common, S.W.  
Gaze, William Henry, W. H. Danks, Thames Ditton  
Greenwood, Arthur, 14, Minories, S.E.  
Greenwood, Major, London Hospital, E.  
Henry, Louis, 34, Amptill Square, N.W.  
Jover, Anthony, 29, Paris Street, S.E.  
May, Albert Edward, 5, Clifton Gardens, W.  
Moritz, Siegmund, Chichester, Manchester  
Nichols, Thomas Vere, Chancery House, L.C.  
Norton, Ritchie Robinson, University Coll. 26, W.C.  
Oram, Richard Randall William, 25, Great Curran Street, W.C.  
Parker, William Herbert, County Asylum, Gloucester  
Reddy, Herbert Lionel, St. Thomas's Hospital, S.E.  
Shaw, Charles Thomas Knox, 8, Guildford Place, W.C.  
Stokes, Richard Lugard, 30, Albert Street, N.W.  
Vasey, Samuel William, 5, Cavendish Place, W.

The following gentleman was admitted Fellow on April 15th, 1878.

Lauder, Christian Gottfried Heinrich, M.D., Erlangen, Freiburg, Germany.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on April 16th.

Ball, William M., Camden Road (St. Bartholomew's Hospital)  
Bentley, William C. Storer, George Street, W. (Middlesex Hospital)  
Birt, Alfred, Ventnor (Guy's Hospital)  
Buxton, Alfred St. C., Shepherd's Bush (Guy's Hospital)  
Chablain, Tom G., Norwich (King's College)  
Clark, Charles A. D., Twickenham (St. Bartholomew's Hospital)

Clarke, Richard, Henton, Oxon (Aberdeen School)  
Clarke, Thomas F., Richmond, Surrey (King's College)  
Flood, Francis P., Leeds (Leeds School)  
Gabb, Claude B., Hastings (St. Bartholomew's Hospital)  
Gilbert, Philip P., Cripplegate (Guy's Hospital)  
Griffith, Walter S. A., St. Albans (St. Bartholomew's Hospital)  
Henderson, Cecil, Clifton (Bristol School)  
Hetherington, George H., Uxbridge (St. Mary's Hospital)  
Kendall, Stanley M., Torquay (Edinburgh School)  
Lowson, David, Huddersfield (Aberdeen School)  
Pearse, Thomas F., Fimborough Road, S.W. (Middlesex Hospital)  
Pinching, William W., Gravesend (Guy's Hospital)  
Powell, Arthur E., Norwich (St. Thomas's Hospital)  
Prichard, James E., Clifton, Bristol (University College)  
Sayer, Thomas, Swaffham (University College)  
Skelding, Henry J., Bayswater (University College)  
Takaki, Kanehiro, Tokio, Japan (St. Thomas's Hospital)  
Wride, Francis G., Oxton, Cheshire (St. Thomas's Hospital)

Five gentlemen passed in Surgery; and, when qualified in Medicine, will be admitted members of the College. Six candidates, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for six months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 11th, 1878.

Benington, Robert Crewdson, Vivian Road, Peckham Rye  
Bisdee, Alfred James, Huthen, Weston-super-Mare  
Brock, Charles De Lisle, St. John's Vicarage, Guernsey  
Bryden, Richard Joseph, Uffculme, Devon  
Burt, Alfred, Ventnor, Isle of Wight  
Cunningham, Robert Frederick, St. David's Hill, Exeter  
Drewitt, Frederick George Davtry, Cumberland Street, Eccleston Square  
Wiles, Frederick William, Wotton-under-Edge, Gloucestershire

#### MEDICAL VACANCIES.

THE following vacancies are announced:—  
BROMPTON PROVIDENT DISPENSARY—Medical Officer. Applications to be made on or before the 26th instant.  
BROMYARD UNION—Medical Officer and Public Vaccinator for the Parish of Cradley. Salary, £50 per annum, and fees. Applications to be made on or before May 4th.  
GERMAN HOSPITAL, Dalston—Honorary Assistant-Surgeon. Applications to be made on or before May 1st.  
GREAT NORTHERN HOSPITAL—Ophthalmic Surgeon. Applications to be made on or before May 6th.  
KENT and CANTERBURY HOSPITAL—Assistant House-Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing. Applications to be made on or before the 25th instant.  
LEITH HOSPITAL—House-Surgeon and Assistant-Surgeon. Salaries, £70 and £50 respectively, with board. Applications to be made on or before May 15th.  
NARBERTH UNION—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.  
RATHDOWN UNION—Medical Officer for Dundrum and Glencullen Dispensary District. Salary, £110 per annum. Election to take place on the 25th instant.  
ROYAL CORNWALL INFIRMARY—House-Surgeon, Secretary, and Dispenser. Salary, £200 per annum, with furnished rooms, coals, gas, and attendance. Applications to be made on or before the 24th instant.  
ST. PETER'S HOSPITAL—House Surgeon. Salary, Fifty Guineas per annum, with board and residence. Applications to be made on or before the 23rd inst.  
TAUNTON UNION—Medical Officer and Public Vaccinator to the Churchston District. Salary, £52 per annum, and fees. Applications to be made on or before the 26th instant.  
TOWCESTER UNION—Medical Officer and Public Vaccinator for the Blakesley District. Salary, £60 per annum, and fees. Applications to be made on or before the 22nd inst.  
TRALEE UNION—Medical Officer for Brosna Dispensary District. Salary, £100 a year as Medical Officer, and £20 per annum as Sanitary Officer, with the usual Registration and Vaccination Fees. Applications to the 20th instant.  
WATERFORD UNION—Medical Officer of Kilmecan Dispensary District. Salary, £100 a year, exclusive of Registration, Vaccination, and Sanitary Fees. Applications up to the 26th instant.  
WESTMINSTER HOSPITAL—House-Physician and House-Surgeon. Applications to be made on or before the 20th instant.  
WORKSOP DISPENSARY—Resident Surgeon. Salary, £120 per annum, with furnished apartments, coals, gas, and attendance. Applications to be made on or before the 25th instant.

#### MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.  
\*EDDOWES, Wm., M.R.C.S., appointed Surgeon of the Salop Infirmary, *vice* Saml. I. Wood, F.R.C.S., appointed Surgeon-Extraordinary.

#### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

#### BIRTHS.

MCDOWALL.—At the Northumberland County Asylum, Morpeth, on April 13th, the wife of F. W. McDowall, M.D., of a daughter.  
ROBERTS.—On April 13th, at Hopeton Villa, Upper Lewisham Road the wife of H. W. Roberts, M.R.C.S.E., of a daughter.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY ....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**TUESDAY.**—Royal Medical and Chirurgical Society, 8.30 P.M. Mr. Nettleship, "On a rare form of Primary Opacity of the Cornea"; Mr. Harrison Cripps, "On the Treatment of Hemorrhage from Punctured Wounds of the Throat and Neck"; Dr. Topham, "On an Abscess within the Thorax, accompanied by Pulsation".

**WEDNESDAY.**—Hunterian Society, 8 P.M. Dr. B. W. Richardson, F.R.S., "On the practice of Total Abstinence from Alcohol in Health and Disease".

**THURSDAY.**—Harveian Society of London, 8 P.M. Special Meeting. Mr. Augustus J. Pepper, "On Abnormalities of Fœtal Development".

**FRIDAY.**—Quekett Microscopical Club (University College, Gower Street), 8 P.M. Mr. J. G. Waller, "On variation in *Spongilla Fluvialilis*".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

## THE LADY MEMBERS OF THE ASSOCIATION.

**MR. HENRY BROWN** of Northallerton wrote to us last week that the report of the last part of the discussion at the special meeting at Birmingham was meagre. What, however, appeared in the number in question was only a brief summary furnished by the reporter, who had had to transcribe the long report of the business which occupied the meeting the first three hours, and reserved the full transcription of his notes to the subsequent number. Mr. Henry Brown added: "The British Medical Association now stands in the anomalous position of having committed itself to frame a by-law so that 'women' cannot be admitted in future; but they will not interfere with the two lady members, Mrs. Anderson and Mrs. Hoggan. Well, this is certainly a nice job. 'We don't want women members: we have power to expel them, but (the Council) won't.' Now, this matter cannot be allowed to rest. In spite of opposition, I shall give the necessary notices, so that the whole question shall be discussed, according to the by-laws, at Bath." We concluded that after reading the speeches in full, he would see that he had apparently misunderstood the view taken by the Committee of Council, who had undertaken to refer the question of the legal status of the two ladies who have been elected members of the Association to the opinions of counsel; and we pointed out to him that Dr. Wade had clearly stated the present position of the Committee of Council in the matter. Mr. Brown now writes to us that he is not labouring under any misapprehension whatever as to what Dr. Wade said or meant to convey in his speech at Birmingham. He adds: "I am determined to bring the question as to whether or not Mrs. Anderson and Mrs. Hoggan are members of the Association forward for discussion. I deny that Mrs. Hoggan and Mrs. Anderson are *de facto* and *de jure* members of the Association." As we understand from the result of the discussion, the Committee of Council are also pledged, first of all, to take counsel's opinion on the subject, whether these ladies are or are not legally at present members of the Association, and are also pledged to bring it forward for discussion. We have already pointed out there is also another course open to any independent member, and that is, supposing that these ladies are legally members, the constitution of the Association provides means by which they would, on a vote of the majority of the members, taken in a prescribed form, cease to be members.

**CORRESPONDENTS** are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

## DR. ABRATH AND MEDICAL ETIQUETTE.

**STR.**—In your issue of last Saturday, the 6th of April, I find you have given a paragraph which is of a nature to damage my professional character. Your *JOURNAL* is widely circulated in this district, therefore it has more power to do me harm. As a general consulting practitioner, and one who performs both general and special surgical operations—such as operations on the eye, ovariotomy, lithotomy, tracheotomy, colotomy, excision of various joints and bones, amputations, etc., likewise as having an extensive general medical consulting practice; having, moreover, to pay to her Majesty's Government heavy taxes—I cannot let my professional character be damaged by either jealous medical men on the *Medical Register*, who style themselves doctors without ever having graduated at an university, nor by individuals who hold some medical or surgical licence, and style themselves surgeons or physicians, yet never have been examined in chemistry; nor will I allow any man, even an editor of any medical or other journal, to interfere with my legal rights and try to damage my professional standing. The *BRITISH MEDICAL JOURNAL* of last Saturday has been shown to some of my patients, to whom it has been pointed out that you accuse me of having gone against the discipline of the Apothecaries' Society, and language has been used on the subject which would sound very curious in a law court. You must be aware that the Apothecaries' Society of London is the oldest medical corporation in England, and that since 1815 it has never admitted any man to examination unless he has had a classical education, besides being examined in all the medical branches of the profession, which include chemistry; and as all our pathological knowledge is based upon physics and chemistry, the Society's diploma must be looked upon as an old standard. The College of Surgeons of England has till quite recently admitted men to examinations without any classical education or examination in chemistry; and the College of Physicians of Edinburgh and the University of St. Andrews, under their by-laws, have done and do the same. I admit that, notwithstanding this, many respectable practitioners hold diplomas from these corporations only. Coming to the point, the holder of the Apothecaries' Society diploma has the privilege of keeping an open shop; and as the Society itself deals in drugs, and of course must have a price-list, he can charge for consultations, visits, and medicines extra, and he has a right to state his charges publicly; therefore, I defy you to prove that *I have acted against the discipline of the Apothecaries' Society*. Daily we see in our newspapers medical men, and even some holding chairs in medical schools in this country, who are, in connection with provident dispensaries, advertising their charges. Some have self-supporting dispensaries of their own, and circulate printed bills setting forth their charges. Provident dispensaries' practice is of a systematic nature, and such practice is not very beneficial either to the profession or the patients. May I ask what interest the yearly paid medical man in general takes in his patients? Of course, the system fills the pocket of a small number of the so-called medical profession—those medical men who publish their charges as a regular thing, and not in self-defence, as I have done. Why do you say nothing to them? Is it that they are Englishmen, and I am a German and have no power to defend myself? If you think so, you are mistaken. I know true Englishmen like justice, and justice I demand, and nothing more. Why did you not in your paragraph state the reasons for which I published my scale of charges? You call them rignaroles: they may be so in your eyes, but nevertheless everything I have stated is the fact. Why did you not state that the chief reasons of the publication was that certain members of the profession and other individuals had spread abroad, in clubs, etc., that I overcharged the public, and that I had brought a farmer into the Sunderland County Court who would not pay my fees? But as regards this case, surely any man with common sense will say that my charges were moderate. A well-to-do farmer, residing six miles from Sunderland, in a place only to be approached by bad driving roads, I charged £1 per visit, medicines extra. Several of the visits were night-visits. Payment was refused, and I had to summon the man to the County Court. The farmer's son-in-law afterwards stated to me that the case would never have gone into court if some medical men had not been at the bottom of it, and stated that the charge was too high. But in several other cases, self-styled doctors and other professional reptiles have spread scandals about me without the least foundation; therefore I think that, as a Licentiate of the Society of Apothecaries (London), I have a right to vindicate my professional character against such insinuations as you have chosen to make, merely on account of my publishing my scale of charges, which are as follows.

1. To the working classes and people of limited income, my charge for consultations at my consulting-rooms, or by visit (if too ill to attend there) at their residence in any part of the town, including medicines, is 2s. 6d.

2. To people in better circumstances to do, from 3s. 6d., 5s., 7s. 6d., 10s. 6d., to £1 1s.

3. For night practice, double charges.

4. If several members of a family are ill in one house, the medicine only is charged extra.

5. Surgical operations, or any visit, near or far, in the country will be charged according to agreement before hand; so also in case of accident or injury from such in town or country.

6. No extra charge for examination in eye-disease with the ophthalmoscope.

Why do you not censure those self-styled doctors and quacks who give licenses as surgeons and physicians, and never examine in their city? The holders of such diplomas are generally the people who stand properly qualified medical men who try to do their duty in their calling. I hope the day will come when we shall get a medical reform, and students will be better educated in practical anatomy, physics, and chemistry; then we will get true medical etiquette, as the practitioner will learn something about the laws of Nature and his duty as a scientific man, and not, as in many instances now, be a licensed empiric only. At present, what is deemed medical etiquette may not improperly be styled humbug, as through it innumerable thousands of persons have had to go to early graves. We have five thousand and more fantastic names for different diseases which the human frame is supposed to be liable to, but which, with a better classification, might be reduced to two or three hundred real ones. Owing to this confusion, we see medical men in our day listening with the stethoscope over the region of the stomach in abdominal aneurism and pronouncing it to be over some region of the heart, or putting the instrument in cases of emphysema over the liver instead of over the lungs. On the other hand, so-called ophthalmic surgeons with so-called high credentials (even London men) have been known to state upon oath in assize courts that the retina

can receive arterial blood only through the arteria centralis retinae, and no otherwise, although these men may have operated for cataract a dozen times more than a Hindoo shepherd without any special anatomical knowledge of the eye whatever. This notwithstanding that my countryman Dr. Richard Liebreich more than twenty years ago proved by anatomical facts, that the retina can receive arterial blood independent of that particular artery. Again, we see that medical men who hold lectureships on pathology or medical jurisprudence, have been ignorant of the efficacy of the galvanic test in paralysis; others do not know how to act in the simplest case of a medico-legal character. That some of these practitioners—I do not care what high or low position they hold—get their brains muddled and speak evil things which are not true of their neighbours is no wonder; but one thing is a blessing, that there are superior courts where slanderers and libellers can be punished.—I am, yours truly,

GUSTAV ABRATH, Doctor of Medicine,  
University Heidelberg; Licentiate of the Apothecaries' Society, London.

Sunderland, April 10th, 1878.

\*.\* The following is the text of the advertisement referred to. It is cut from the *Sunderland Echo* of April 1st, 1878.

*"The Dispute of Medical Charges in County Courts."*

"To the Editor.—Sir,—In London there are a large number of medical men, some of whom attend upon members of the Royal Families resident there; some hold appointments as professors, or are lecturers at medical colleges, and others fill positions at the various hospitals and dispensaries. Now, it is an admitted fact, that these gentlemen cannot and do not agree with other medical men—say, in their evidence upon a *post mortem* examination made, it may be, on a sweep, a barrister, or an emperor—and hence when a dispute arises, they invariably ventilate the subject of the dispute in the columns of the metropolitan press, wherein they are enabled to cheaply advertise their medical works, setting forth the virtues of some fancy remedy, or trifling matter, such as whether a fever-patient shall take "iced milk" instead of "frozen milk". This is one method of using the columns of a newspaper by medical men in the settlement of a dispute. On the other hand, there are to be found batches of medical men, both in London and the provinces, who are connected with provident dispensaries, who do not hesitate to use the public press as a means to advertise their charges. I am led to make these observations, because I think it high time when a provincial practitioner comes to grief through the jealousy and machinations of certain members of his profession, and other individuals. His professional character is damaged, in a covert and insidious manner, by statements that he overcharges the public—statements which are not true, but which operate in such a way as to cause his patients to refuse payment of his medical fees, etc.; therefore, the ill-treated provincial practitioner has no other course open to him but to state his grievance through the medium of the local press. Slanderers have busily circulated, not only in the clubs, but other places, that I overcharged the public; and this, together with a case I recently had in the County Court at Sunderland, compels me, in vindication of my professional character, to publish in the newspapers my scale of charges." (The scale is the same as that given above.)—Yours truly, GUSTAV ABRATH, Doctor of Medicine, Surgery, and Midwifery (by double examination), University of Heidelberg; Licentiate of the Society of Apothecaries, London.—Sunderland, March 18th, 1878.

J. P. S. (Glasgow) is alarming himself unnecessarily. He should take the advice of a respectable local family practitioner, and avoid the alarmist advice of advertisers and quacks generally.

*ATTENDANCE ON FAMILIES OF MEMBERS OF THE PROFESSION.*

SIR,—My attention has been arrested by the letters in the *JOURNAL* under the above heading; and, as the question is of some importance, I will try briefly to give my experience. When I was only a pupil in London, I had occasion to consult the late Sir James Clark, and I can never forget the words made use of by him on my tendering him a two guinea fee—viz., "Young man, if ever through life you want to insult a professional brother, tender him a fee." During twenty-five years in harness, I have always accepted that saying as my guide, never refusing service to, or accepting such from, the members of our truly noble (if exercised rightly) profession with the idea of a cash consideration; and, although I and mine have consulted the profession largely, I have never received an account excepting the one enclosed in my letter published by you on March 16th for attendance on my daughter. I regret this the more, as it precluded me from the pleasure of acknowledging the services by a "souvenir" of the confidence I reposed in the brother to whom was entrusted my wife's or child's health. I may also state that I am married to the only daughter of a late surgeon, who, prior to marriage, spent most of her time in visiting in various parts of England and Wales, where she often required professional assistance, being delicate. In no instance did she ever offer, or her late father pay, for such in cash, although on her return home a suitable acknowledgment was always made in a tangible form. This I take to be the proper mode of expressing our gratitude; for what can raise a man more in his own estimation or public opinion than the fact of his being entrusted with the life of a brother or any member of his family? And in my practice I have always carried this further. I never sent an account to a governess, a poor curate, or an actor; and, I am happy to say, I never lost by such conduct. Although not now in harness, I would pursue the same course again toward all those who, from the very nature of their callings, had to keep up an appearance on generally a very small salary, and whom God help should sickness overtake them or theirs. At the same time, I certainly am opposed to gratuitous advice and the "club" system, as at present carried on. As to the arguments used by "Another Member" talking about his card being lost or stolen, does he mean to say or think professional men are so wanting in discrimination as not to detect an impostor? Again, in my case, the medical attendant did know well his patient was the daughter of a brother practitioner, and more than one or two letters passed between us relative to the case.

In conclusion, I endorse all "Senior" says in his letter; and as the question is being so well ventilated, I hope not to trespass again on your valuable space in reference to this (to me) unpleasant subject.—I am, etc.,

MEMBER.

*REVOLVING MIDWIFERY FORCEPS.*

SIR,—I notice that in your account of the March meeting of the Glasgow Medico-Chirurgical Society, it is stated that Dr. J. T. Whittaker showed a form of revolving midwifery forceps, the two halves being connected by a ball and socket-joint, which enabled one blade to move round the other. Will you allow me to state that this is not a new instrument? One was submitted to me, as an American invention, about four years ago. The objection to it appeared to be that, though not difficult to apply, it was next to impossible to keep the clamps in position.—I am, Sir, yours truly,

Birkenhead, April 2nd, 1878.

FRANCIS VACHER.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**COMPOSITION AND QUALITY OF THE METROPOLITAN WATER IN MARCH 1878.**  
The following are the returns made by Dr. C. Meymott Tidy to the Society of Medical Officers of Health.

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen used to Oxidise Organic Matter.	Nitrogen As Nitrates, &c.	Ammonia.		Hardness. (Clarke's Scale.)	
				Saline.	Organic	Before Boiling.	After Boiling.
<i>Thames Water Companies.</i>	Grains	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction ..	21.20	0.051	0.120	0.000	0.007	13.7	3.3
West Middlesex ..	21.10	0.062	0.105	0.000	0.008	13.7	3.7
Southwark and Vauxhall .....	20.90	0.061	0.120	0.000	0.011	13.2	3.3
Chelsea .....	20.90	0.048	0.120	0.000	0.010	13.7	2.8
Lambeth .....	22.20	0.062	0.114	0.000	0.011	13.7	2.8
<i>Other Companies.</i>							
Kent .....	26.49	0.060	0.195	0.000	0.002	17.0	4.6
New River .....	20.20	0.024	0.134	0.000	0.007	13.7	2.8
East London .....	22.40	0.032	0.105	0.000	0.007	14.3	4.2

*Note.*—The amount of oxygen required to oxidise the organic matter, nitrates, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters, the quantity of organic matter is about eight times the amount of oxygen required by it. The water was found to be clear and nearly colourless in all cases.

*MENSTRUATION AND THE CURING OF MEAT.*

SIR,—There have been some interesting letters on the above subject in the *JOURNAL*, and the following question, which could readily be answered by any of the female members of our profession, naturally arises. If such bad results accrue from a woman curing dead meat whilst she is menstruating, what would result, under similar conditions, from her attempt to cure living flesh in her midwifery or surgical practice?—I am, etc.,

SURGEON.

The following communications have been handed to the General Manager:—Mr. Campbell, Glasgow; Editor of "Brief".

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Chicago Times; The Manchester Guardian; The Berkshire Chronicle; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Daily Courier; The Middlesex County Times; The Liverpool Evening Albion; The Daily Courier; The Kelso Chronicle; The Fifehire Herald; The Merthyr Express; The Carnarvon and Denbigh Herald; The Surrey Advertiser; The Stroud News; etc.

\*.\* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

*COMMUNICATIONS, LETTERS, etc.,* have been received from:—

# THE GOULSTONIAN LECTURES ON THE LOCALISATION OF CEREBRAL DISEASE.

*Delivered at the Royal College of Physicians of London.*

By DAVID FERRIER, M.D., F.R.S., F.R.C.P.,

Professor of Forensic Medicine in King's College; Assistant-Physician to King's College Hospital; etc.

## LECTURE III (*concluded*).—March 22nd.

*Lesions of the Parieto-Temporal Region.*—There remains, therefore, a region, situated between the motor area and the occipital lobes, in which it is natural to look for a central differentiation of these tracts. This region includes the supramarginal lobule and angular gyrus or inferior parietal lobe, the convolutions of the temporo-sphenoidal lobe on its external and internal aspect, viz., the superior, middle, and inferior temporo-sphenoidal convolutions, the occipito-temporal convolutions (lingual lobule, fusiform lobule), the uncinate gyrus, and hippocampus major or cornu Ammonis. (Fig. 1.) We may call the whole of this the parieto-temporal region. It has, I think, been shown conclusively that experimental lesions of the cortex in this region in the lower animals—a region in which I claim to have demonstrated the existence of individually differentiated centres of special sense—are capable of producing impairment or paralysis of sensation on the opposite side of the body.

This has been shown more particularly as regards vision (which seems specially to have been investigated), by the experiments of McKendrick on pigeons, and by those of Hitzig, Goltz, etc., on dogs. Without precisely defining the regions, lesion of which causes sensory disturbances, we may take it as firmly established that unilateral lesions of the cortex are capable of causing such effects in the lower animals. And here it will be convenient to consider the views advanced by Goltz, with respect to the effects of cortical lesions.\*

According to Goltz, it is not so much the position as the extent of the injury on which the phenomena of cortical lesions depend. These he finds to be a conjunction of motor paralysis or paresis, tactile anaesthesia, and blindness or impairment of vision on the opposite side. I need scarcely say, from what I have already brought before you, that if that is the type of cortical lesions in the dog, then we must look upon canine and human pathology as having no resemblance to each other. But it requires very little examination of Goltz's facts to discover that his views are equally at variance with the facts themselves, as with those of clinical medicine and pathology. Instead of laying bare a distinct region in the brain, and accurately limiting his destructive lesion to the part the functions of which he is desirous to investigate, he merely trephines a hole or holes in the temporal region and destroys the cerebral substance by squirting it out with a strong stream of water. This method he adopts in order to avoid risk of hæmorrhage or subsequent meningitis; and therefore, to keep the animal alive as long as possible. While we may credit it with securing the latter object more or less, it is clearly impossible to say what extent of brain-substance may thus be rendered functionless; and that it produces profound derangement of the whole cerebro-spinal system, is evident from the frequently fatal consequences resulting from this procedure. The extent of grey matter destroyed or rendered functionless, Goltz himself admits, it is impossible to estimate, and he nowhere attempts it in the record he has given of his experiments.

These are fatal objections to Goltz's experiments, as bearing on the question of cerebral localisation. They are to be looked upon as experiments only on cerebral lesions. The explanation of his results is, I think, easily afforded by the facts to which I will presently call your attention, as well as by the abovementioned experiments of Veyssière as to the effect of lesion of the posterior part of the internal capsule. These latter, however, Goltz seems to have altogether ignored, as he makes no allusion to them.

The situation usually chosen by Goltz for his trephine openings and syringing operations is such as to, almost without fail, ensure damage of the sensory fibres of the internal capsule; and he has, in a rude way,

practically produced the same results as Veyssière obtained by careful limitation of his experimental lesion.

While Goltz's description of the phenomena themselves resulting from this procedure may be accepted without question, his theory that the effects of cortical lesions depend more on their extent than on their position, must, I think, be unhesitatingly rejected.

I will now give you a brief *résumé* of the results of my experiments on the brain of monkeys, full details of which I have published elsewhere.\* On these facts I take my stand, and hold that they establish the differentiation and localisation of special sensory centres in the cortex.

*Angular Gyrus* (fig. 15 [13] [13']).—Electrical irritation of the angular gyrus in the monkey causes movements of the eyeballs, pupils, and head, which are to be taken as reflex or associated signs of subjective visual sensation, for the reason that destruction of this region causes no motor paralysis whatever, whether of eyelids, ocular muscles, or pupils. But unilateral destruction has the effect of causing temporary blindness of the opposite eye, while bilateral destruction causes total and permanent blindness in both eyes. Hence it appears that each hemisphere is in relation with both eyes, and the destruction of this centre in one hemisphere is not necessarily followed by complete or permanent blindness. This conclusion is confirmed by Goltz's experiments on dogs, and is in harmony with the researches of Landolt in regard to the affection of both eyes in cerebral hemianæsthesia depending on lesion of the posterior third of the internal capsule.

*Superior Temporo-sphenoidal Convolution* (fig. 15 [14]).—Electrical irritation of this region causes twitching of the opposite ear and other reflex indications of excitation of subjective auditory sensation. Destruction causes no motor paralysis whatever; but, though it is certain that hearing is at least impaired on the opposite side, the difficulty of ascertaining the conditions of auditory perception in animals, when only one ear is affected, is such as to render it impossible to speak definitely as to the extent and duration of the affection of hearing; whereas, when these centres are destroyed bilaterally, there seems to be total loss of the sense of hearing; meaning by that, auditory discrimination as contradistinguished from mere auditory reaction.

*Subicular Region.*—Irritation of the lower extremity of the temporo-sphenoidal lobe, or region of the subiculum cornu Ammonis, causes movements of the nostril and head indicative of excitation of subjective olfactory sensation. Destruction causes no motor paralysis, but is followed by loss of smell on the same side; and, when the lesions invade not merely the subiculum but the neighbouring regions on one side, taste also is affected on the opposite side of the tongue. Bilateral lesions cause complete loss both of taste and smell.

*Hippocampal Region.*—On account of the concealed position of this region, it is impossible to cause localised irritation free from all complication; nor is it possible to destroy it, without injuring other parts of the hemisphere. I found, however, that only in cases in which this region was involved along with others, there occurred impairment or abolition of tactile sensation on the opposite side; and when the region of the hippocampus and uncinate gyrus was ploughed up in such a manner as to avoid the internal capsule and the medullary fibres of the other cortical regions (with the exception of part of the occipital lobe), tactile sensation was abolished on the opposite side, sight and hearing remaining unimpaired. A condition resembling motor paralysis was also induced; but in reality, a functional paralysis depending on the abolition of tactile and muscular sensation, such as occurs from division of sensory nerves.

Such being the indications furnished by experiments on monkeys, we may now proceed to consider the effects of disease of the corresponding regions in the human brain. The facts I am about to quote seem to point to a remarkable, and apparently irreconcilable, discrepancy between human pathology and experimental physiology. Cases are on record in which lesion or some form of degeneration has been found in one or other of all these so-called sensory areas, and in which no affection of sensation has been observed. Lesions here are usually said to be latent.

First, as to the cases: MM. Charcot and Pitres† report a case, latent as regards symptoms, in which there was found a yellow softening of the cortex of the right hemisphere, occupying the posterior half of the island of Reil, the posterior two-thirds of the inferior parietal lobule, comprising the angular gyrus, and the upper or posterior half of the second and third temporo-sphenoidal convolutions. (Fig. 25.) There was no secondary degeneration of the spinal cord.

M. Pitres‡ records a case of extensive hæmorrhage into the medullary substance of the left temporo-sphenoidal lobe, in which, though

† *Revue Mensuelle*, No. 1, p. 10.

‡ *Lesions du Centre Orale*, p. 54.

\* Pflüger's *Archiv für Physiologie*, Band xiii, Heft i; 1876.

consciousness was deeply affected, there was no real paralysis and no lateral distortion or conjugate deviation of the eyes. He quotes a case reported by Thibault,\* also latent as regards sensory or motor symptoms, in which, in addition to a layer of extravasation on the posterior three-quarters of the left hemisphere, there was found, in the

sphenoidal lobe, a large extravasation extending from its anterior extremity to within three centimètres of the posterior extremity of the hemisphere.

Sabourin† has recorded a case of extensive lesion of the sphenoidal and occipital convolutions in which there was no paralysis.

MM. Charcot and Pitres‡ also give a case in which the chief symptoms were a state of dementia and very marked itching of the chest and abdomen without apparent cause. After death, a yellow softening was found in the left hemisphere, occupying the first and second occipito-temporal convolutions, commencing about one centimètre behind the anterior extremity of the temporo-sphenoidal lobe, and extending backwards to within about three centimètres from the tip of the occipital lobe. (Fig. 26.)

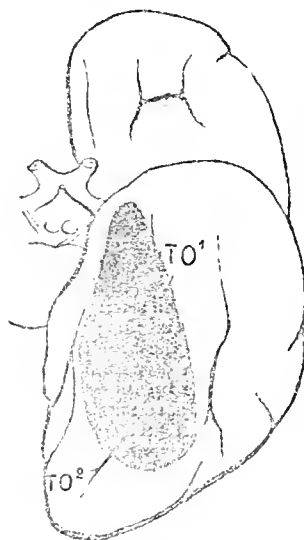

fig. 6.

M. Sabourin communicated to MM. Charcot and Pitres a case exactly similar to the above, and another in which a yellow softening existed in the *cuneus* and posterior two-thirds of the quadrilateral lobule of the left hemisphere, likewise latent as regards symptoms.

A case is reported by Humbert§ of abscess in the anterior and inferior part of the right temporo-sphenoidal lobe, resulting from suppuration of the ear, in which there were no special symptoms indicative of such a grave cerebral lesion.

Of similar affections of this part of the brain in connection with otitis, and with nothing but the general symptoms of cerebral abscess, I might quote a multitude. References are given by Pitres to cases of this kind related by Ormerod, Sir W. Gull, Blondeau, Haslewood, Homolle, and Renault.

Of lesions specially confined to the hippocampus, I have not been able to find any on record, except those of Bouchet, Meynert, etc., in respect to degeneration or sclerosis of the hippocampus in chronic epileptics. Bouchet|| in twelve out of forty-three cases which he examined, noted the existence of sclerosis in one or both hippocampi, but he did not attach any special importance to this; as induration of the brain in chronic epilepsy he looked upon as a general affection, of

which this was only a local manifestation. This condition of the hippocampus has been observed also by Cazauvielh, Foville, Lelut, Delasiauve, Bourneville, in epileptics. In 1868, Meynert\* called special attention to this degeneration of the hippocampus in epileptics, giving nineteen cases in which one or other hippocampus was indurated or atrophied. Meynert, without looking upon this as the cause of epilepsy, thought that there was some special relation between this degeneration and the lesion on which epilepsy depended. In a recent paper, Hemkes† states that he has seen atrophy of the hippocampus in only six out of thirty-four cases. Beyond the fact of the existence of such degeneration in epileptics, we have no record of the exact symptoms in the cases in which it was found. Meynert‡ believed that the optic tracts had special relations with this region; and he gives four cases of disease situated in or near the hippocampus and fusiform lobule, in which disorders of vision were observed. The cases, however, are altogether deficient as regards ophthalmoscopic appearances, on which it would be necessary to have some information before coming to a conclusion as to whether the disorders of vision were the direct or indirect results of the cerebral disease.

I have quoted a number of cases of unilateral lesion of the sensory regions, mostly of a chronic form, in which no special symptoms were noted. It may be said that the absence of symptoms in all these cases may be accounted for by functional compensation by the same or the opposite hemisphere. Yet there are on record cases of traumatic lesion, also apparently latent, which would militate against this idea, supposing them in every respect carefully investigated.

M. Herpin§ has recorded a case of fracture of the skull and injury of the brain in the region of the squamous portion of the temporal and greater wing of the sphenoid. The man did not lose consciousness, and, from the time of the accident till death, four days afterwards, nothing was observable, either as regards motility or sensibility. After death, a contusion of the third degree was found in the inferior aspect of the temporo-sphenoidal lobe (which side not stated), extending five centimètres in an antero-posterior direction, three centimètres in breadth, and affecting more particularly the middle and external (inferior) temporo-sphenoidal convolutions; a situation corresponding exactly to the cranial injury. A clot, of the size of a bean, existed at the anterior extremity of the lesion. A case in some respects similar has been put on record by Alcock.|| This was a case of cranial injury, followed by restlessness and sleeplessness; and only on the third day after the accident did the patient seem to hear when spoken to. He gradually got worse, and died on the thirty-third day after the accident, without being affected by paralysis. Wilfulness and obstinacy were his most prominent mental symptoms. On the right hemisphere, there was a patch of ecchymosis, of the size of a florin, in the pia mater, over the upper extremity of the superior temporo-sphenoidal convolution, but the brain-substance underneath was not injured. On the left side, "the portion of brain corresponding to the lower part of the squamous portion of the temporal bone was soft and pulpy, being easily washed away by a stream of water, leaving a cavity with ragged walls, the area of which equalled that of half-a-crown, and about a quarter of an inch in depth. The ventricles contained an excess of serum". The only indication as regards sensory affection in this case was the apparent want of auditory perception at first; but whether this was a part merely of the general dazed condition of the man, or as the result of affection of the auditory centres, it is impossible to say definitely, though the position of the lesions might be taken in favour of the latter.

I have not been able to find any cases of bilateral lesions of the hemispheres in corresponding parts of the sensory area without such profound mental disturbance as to render the determination of the existence or absence of sensory impairment a matter of impossibility. This is greatly to be regretted, as on these the question of special sensory localisation in man to a large extent depends.

But if we confine our attention to the cases of unilateral lesion of the sensory area which I have mentioned, and compare the negative results as regards sensation, whether with chronic or sudden lesions of the sensory regions in man, with the affections of sensation, carefully observed and confirmed by many physiologists, which result from similar cortical lesions in the lower animals, we cannot but be struck by the discrepancies which exist. To account for these, we must adopt one or other of two suppositions: either, taking the facts as equally well established, that the parallel which has hitherto been shown to exist between the brain of man and that of the monkey and the lower

|| *Lancet*, Marc 10th, 1877.

animals now suddenly ceases to hold, and that, in respect to sensory localisation, the brain of man is constituted on a totally different type from that of the lower animals; or, if this be regarded as improbable, that the latency which is said to characterise lesions of the sensory area in man is a latency not so much of actual symptoms as of observation.

M. Pitres\* is of opinion that the sensory fibres which are gathered together in the posterior third of the internal capsule, instead of distributing themselves like the motor fibres to individually differentiated areas in the cortex, spread themselves indifferently over the whole occipito-sphenoidal region. But this does not remove the difficulty; for we should then expect that extensive lesions of this region should cause general impairment of all the sensory powers on the opposite side together; a hypothesis which the clinical records no more support than that of special localisation. And it would seem strange if there should be a distinct differentiation of centres of motion, and a general *confusion* in the centres of organs so highly specialised as the organs of sense. This is a supposition which I cannot entertain, and for which I see no substantial grounds. That the organs of sense may be more bilaterally represented in each hemisphere in man than in the lower animals, is not impossible. That bilateral representation does exist to a large extent, and particularly as regards sight and hearing, is in accordance with the facts of experiment, and is sufficient to account for the absence of any very obvious impairment of these faculties in cases of unilateral lesion of a slowly progressive character. But that there is no impairment at all of sensory perception or discrimination in *sudden* unilateral lesions, or even in *chronic* lesions, is a fact which I do not admit as proved; and I adopt the alternative supposition, that the latency has been in observation rather than in symptoms.

This may seem a sweeping charge, and a very summary method of disposing of difficulties; but I cannot help expressing the frequent disappointment I have experienced in reading through multitudes of cases of cerebral lesion, which might have served to throw light on this subject, and finding no indication of any attempt having been made to investigate the conditions of special sense. Considering the perfunctory manner in which this is so commonly carried out, if investigation be made at all, and the frequent omissions in this respect which are to be found in the records of even our most accurate and competent clinical observers, I cannot take mere absence of remark as proof of negation of symptoms, unless there be clear evidence that the various points had been fully and fairly investigated, and the negation of symptoms positively established. For the clinical facts are not all of the same negative order as those I have brought before you, and many of them are, in my opinion, capable of satisfactory explanation only on the views I have advanced.

Let us take first the question of affections of sight directly dependent on cerebral lesion. Here, of course, we must eliminate all those cases in which impairment or abolition of vision is caused by changes in the optic nerve and retina, secondary to intracranial disease wherever situated. Hence most of the records of cerebral disease, before the invention of the ophthalmoscope, and, I may add, very many since, are for the most part worthless in this relation. But the following case, which is recorded by Abercrombie,† and which I give in his own words, has a special value. "The effect of superficial inflammation of the brain or its membranes is well illustrated by another case related by Dr. Anderson, in which the disease took place under his own eye. A boy suffered from an injury of the head, the depression of a considerable portion of the *right parietal bone*, the depressed portion being forced through the dura mater and driven inwards upon the brain. *He had paralysis of the left side, and the left eye was insensible.* The depressed portion being removed, the paralysis was greatly diminished, and the eye recovered a considerable degree of vision. On the third day after the operation, the wound in the dura mater was inflamed, with considerable tumefaction; and immediately the left leg and arm became paralysed, the paralysis being accompanied by convulsion; and *the left eye also became again insensible.* He had frequent convulsion of these parts for several days, the right side not being in the least affected, when, suppuration having taken place, all the symptoms subsided" (p. 121-2). Now, though recovery took place, and therefore the case is incomplete in an anatomical point of view, it is clearly a case of cortical lesion, and possesses all the typical features of such; and that the affection of the opposite eye, which proceeded *pari passu* with the motor symptoms, had a similar cause—viz., lesion of the cortex—is, I think, unquestionable. Though the exact extent and position of the depressed fracture is not stated, yet, as it was in the parietal

region, we may conclude that the lesion involved not only the cortical motor area, but also the *visual* centre, which is in close proximity to it under the parietal eminence (fig. 3). This case, in my opinion, distinctly confirms the sensory localisation which I have arrived at by experiment, or at least is explicable only in this way.

The same author also quotes another case related by John Bell, in which, from injury to the head, extravasation of blood occurred on the surface of the brain, for which the patient was repeatedly trephined. Local inflammatory attacks with suppuration occurred from time to time on the left hemisphere after the trephining. These local attacks, when they occurred towards the anterior part, were accompanied by double vision; but, "when they were towards the posterior part, there was not double vision, but a state of vision in which a candle was seen with a halo round it" (p. 122).

I mention this case chiefly because it harmonises with the observations of Hughlings Jackson, already referred to, in respect to the frequent association of optical illusions, coloured vision, etc., with disease of the posterior lobes. These spectra are the counterpart of the motor discharges caused by irritative lesions of the motor centres. That they should occur more particularly with lesions situated towards the posterior aspect of the hemispheres, is quite in accordance with the localisation of the visual centre in the angular gyrus. These sensory discharges in connection with epilepsy of cortical origin, whether in the domain of sight, hearing, smell, taste, or tactile sensation, are without doubt to be looked upon as indications of irritative lesion of the sensory centres, though we have not yet sufficient material to enable us, from a purely clinical point of view, to connect any particular form of sensory discharge with a specially localisable lesion, unless we regard it as established in respect to optical illusions. Not unfrequently the sensory centres are discharged together, as in a general unilateral convulsion, and there is no clear discrimination of one form of sensation from another. This was well exemplified and graphically described to me by a highly intelligent patient, who told me that his epileptic attacks (*petit mal*) were ushered in by a "horrible smell of green thunder", or by some equally strange compound of smells, colours, and sounds, inextricably intermingled.

Reverting to the impairment of sight in connection with destructive lesions, it has been remarked by Dr. Bastian that not unfrequently, in cases of thrombosis of the posterior cerebral artery, vision is impaired on the side of motor paralysis.\* This he attributes to affection of the opposite optic tract, or to the opposite side of the corpora quadrigemina. But, as lesion of the optic tract would seem to be associated rather with bilateral hemiopia than with unilateral amblyopia, and as lesion of the corpora quadrigemina is generally accompanied by more complex symptoms than mere motor hemiplegia, it seems to me that the impairment of vision may be attributed to sudden interference with the visual centre. I advance this only as a suggestion, without pretending to pronounce definitively on the subject.

Apart from the evidence of auditory discharges and subjective auditory spectra of various kinds in connection with epilepsy and other cerebral affections, I cannot find any altogether satisfactory evidence of impairment or abolition of hearing in connection with destructive lesions of the cortex. Hughlings Jackson repeatedly emphasises the statement, that he has never met with deafness as the result of disease of the cerebral hemispheres directly.

But, though we may admit, in accordance with the results of experimental physiology, that unilateral destruction of the centres of hearing and sight need not cause actual blindness or deafness of a complete or enduring character, there are certain facts which tend to show that unilateral lesions of these centres may produce what we may call *sub-junctive* deafness and blindness. Such conditions are not unfrequently classed with aphasia, and may occur with it; but they may occur *without* true aphasia or speechlessness. They have been termed by Kussmaul "word-blindness" and "word-deafness" (*verbalis et auditus verbalis*). These two conditions may occur separately or in association. In the one case, though a man may be able to speak and write, he cannot translate written symbols into ideas, though he may understand articulate sounds; in the other, he may be able to read, though he cannot understand spoken words, or he may be unable to do either. In neither case is there actual objective blindness or deafness. In a case of word-deafness of this kind reported by Wernicke,† there was, besides a general atrophy of the convolutions, a thrombotic softening of the first and a large portion of the second tempo-sphenoidal convolution of the left hemisphere. The auditory centre was thus destroyed. A very interesting case of subjective or word-blindness has been recorded by Dr. Broadbent.‡ The essential points are thus

summed up by him. "After an acute cerebral attack, absolute inability to read printed or written words (except own name), while the patient wrote correctly from dictation, and composed and wrote letters with a little prompting. Inability to recall the name of the most familiar object presented to his sight, while he conversed intelligently, employing an extensive and varied vocabulary, making few mistakes, but occasionally forgetting names of streets, persons, and objects. Death from apoplexy; extensive atheroma of cerebral vessels; old clots in substance of left hemisphere, with softening of adjacent substance to outer side of lateral ventricle, at junction of descending cornu. Recent hæmorrhage in same situation." The primary lesions on which the softening and subsequent fatal hæmorrhage appeared to depend were two old clots. The first, of the size and shape of an almond, was loosely imbedded in the inframarginal gyrus or superior temporo-sphenoidal convolution, about opposite the junction of the upper third with the lower two-thirds of the descending cornu. The other, which Dr. Broadbent regards as the more important and the cause of the softening which led to the fatal hæmorrhage, was a clot of the size of a bean, surrounded by softening, situated at the upper extremity of the fissure of Sylvius externally, and at the junction of the descending cornu with the body of the ventricle internally. This, it will be seen by reference to fig. 16, is in the region of the angular gyrus and supramarginal lobule, the homologue of the visual centre in the monkey. These cases I take to be in harmony with the views I have elsewhere expressed, that the sensory centres are also the substrata of corresponding sensory memory and sensory ideation. In the one of these cases (Wernicke's) in which the auditory centre was the seat of lesion, there was paralysis of auditory ideation; in the other (Broadbent's), in which the visual centre was the seat of disease, there was paralysis of visual ideation, more particularly in connection with articulate symbols or their visible equivalents.

The paralysis of visual and auditory ideation in special reference to words in these cases is accounted for by the fact, that in both the disease was situated in the visual and auditory centres of the left hemisphere, between which and the speech-centre we may reasonably suppose there exists a more intimate organic or functional connection than between this and the sensory centres of the right hemisphere. But, as regards sensory discrimination and sensory ideation in general, we have not the same grounds for regarding the right hemisphere as subordinate to the left, as is the rule in respect to voluntary movements and motor ideation; for, with equally acute sensibility on both sides, we find that, for delicate sensory discrimination, some invariably use one eye or one ear in preference to the other, and therefore the opposite cerebral hemisphere. Thus the same individual will use his right eye for microscopic work, and his left ear for auscultation; which we may take to mean that his left visual and right auditory centres are more especially cultivated and developed.

Hence we may conclude that unilateral lesions of the sensory centres will vary considerably in respect to their effects on sensory ideation, according as the lesion is on the side of the more or less developed centre. It is not impossible, therefore, that what Hughlings Jackson terms "defective perception" may be more common with lesions of the sensory regions of the right hemisphere, if these be more commonly cultivated and developed.

Before passing from this subject, I would refer to an interesting case related by Dr. Banks\* of Dublin, in which, though unfortunately no *post mortem* examination could be made, there are certain facts bearing on the question as to whether actual deafness may occur from cerebral disease. In this case, after a sudden cerebral seizure, but without coma or paralysis, the patient was found to be incapable of understanding either speech or writing, though he could both speak and write. He was found to be completely deaf, taking no notice of what was said to him, or even of the loudest noises; and, indeed, he used to allude to his deafness himself. One day, he said he could neither hear nor read; "only a little could read the words, but not take in the meaning". This patient died ultimately of coma and right hemiplegia; but no *post mortem* examination was allowed. Unless we suppose, in this case, that the patient had a separate lesion in both auditory nerves or both ears, occurring simultaneously with his cerebral lesion, we may take it as a case of deafness depending directly on cerebral disease; but whether the lesion was unilateral or bilateral, the absence of a *post mortem* examination unfortunately renders it impossible to decide.

Affections of smell and of taste, we have seen, occur with affections of the other senses in cerebral hemianæsthesia; but affections of smell alone, or of taste and smell combined, may occur without other sensory impairment in connection with certain forms of cerebral lesion.

As regards smell, there seems to be some discrepancy between my localisation of the olfactory centre and the facts of cerebral hemianæsthesia. I find that destruction of the subicular region causes loss of smell on the same side; while in hemianæsthesia the impairment of smell is on the side opposite the cerebral lesion. I have endeavoured to account for this by the fact, discovered by Magendie, that abolition of the common sensibility of the nostril by section of the sensory branches of the fifth nerve causes loss of smell; and, as in hemianæsthesia the sensibility of the mucous membrane of the nostril is lost, so we may consider this to be a sufficient cause of the unilateral anosmia. I see no reason to doubt the validity of this explanation; but I would supplement it by another consideration. Though the outer root of the olfactory tract can be directly traced to the subiculum of the same side, it is not unlikely that the inner root passes on to the opposite hemisphere with the other sensory tracts; and hence each hemisphere may maintain a bilateral relation with the organ of smell. If this were so, then the partial impairment of smell, which would result from lesion of the special sensory paths of the opposite hemisphere, would be rendered more complete by the simultaneous abolition of common sensation in the nostril. I cannot give anatomical evidence of this arrangement, for the inner root of the olfactory tract has not been traced by Meynert beyond the corpus striatum; but that it ends here is, I think, more than improbable.

Unilateral anosmia has been observed in many cases of cerebral lesion, and on the same side as the lesion; but, without a necropsy, it is of course difficult to decide whether this was due to direct lesion of the olfactory tract, or of its centre. Several such cases have been reported in connection with aphasia, the anosmia being on the left side.\* A good many cases are now on record of loss of smell, or combined loss of smell and taste, as the result of blows on the head, more particularly of the vertex or occiput.†

As regards the anosmia, the mode of causation suggested by Ogle,‡ viz., injury by counterstroke to the olfactory nerves, bulbs, or tracts, seems in every way satisfactory. To the loss of smell, Ogle further ascribes such affections of taste as may be combined with it, viz., the impairment or abolition of the perception of flavours, which are a compound of smell and taste. And, indeed, in many of the so-called cases of loss of taste and smell, taste proper does not appear to have been affected. Hence they may be accounted for in the manner indicated by Ogle. But even when there is absolute loss of smell, we find cases in which taste is but little interfered with. A patient of mine who had suffered from complete anosmia for six years, dating from a fall on his head which had rendered him temporarily unconscious, made no complaint as regarded his power of taste, as he could distinguish all the ordinary articles of food from each other, and could clearly perceive the flavour of onions. Yet, though there was no obstruction of the nasal passages, anteriorly or posteriorly, he could recognise no smell in assafoetida or musk; acetic acid, he said, caused some sensation about two-thirds up the nostril, but no real odour. I have no doubt that in this case there had been rupture of the olfactory nerves or tracts; but the mere loss of smell is incapable of accounting for the symptoms in another case which I have seen. This patient had lost both smell and taste in consequence of a fall on his head into the street six years before. I was not aware until lately that my colleague Dr. Burney Vero had already brought the particulars of the same case before the Clinical Society,§ and, therefore, the subsequent history of the patient will be all the more interesting. This man had not merely total loss of smell, but also total loss of taste proper, such as for bitter, sweet, salt, sour, etc. One day, in fact, when suffering from pain in the stomach, he swallowed a glass of what he took to be brandy, and was not aware it was vinegar until the aggravation of his pain made him ask his wife what was in the bottle. While under Dr. Vero's care, and taking iodide of potassium, he recovered taste to some extent, but he did not, as he told me, recover smell, though he once or twice had something like a subjective sensation of camphor or burnt wood. When he left off the iodide, he became as bad as before. This was in 1872. In 1875, when he came under my care for another affection, he had absolute loss of taste and smell, and had given up all thoughts of recovery, and had tried to accommodate himself to circumstances. Again, on the administration of iodide of potassium, taste returned to some extent, but there was no improvement as regards smell, with the exception of an occasional subjective sensation;

and a relapse again occurred on leaving off the medicine. I lost sight of him till the end of 1876, and found him in his original condition. In January, 1877 I began to treat him with the constant current (ten cells gradually increasing) directed transversely through the head in the zygomatic fossæ, varied occasionally by the application of one pole here, and the other on the bridge of the nose. After one or two applications, while he felt somewhat giddy, various subjective smells were experienced during the passage of the current, which he described as "gassy", "rank", etc. At the end of a week of daily treatment with the current, he began to smell strong odours; subjective sensations also occurred at intervals, and taste became more acute. He gradually and steadily improved, and, after a few weeks' treatment, the power of smell returned, so that he could recognise such things as assafœtida, musk, coffee, tobacco. He could readily distinguish between one smell and another, but continued to have some difficulty as to identification of the substance. There has been no relapse, and now (Feb. 28th, 1878), at the end of a year, he continues to enjoy perfect taste, and his powers of smell, which were never very acute, he thinks are as good as ever.

I will not attempt to decide what was the exact *modus operandi* of the galvanic current, whether it acted by stimulation of the olfactory nerve direct, or by stimulation of the cerebral centres of taste and smell; but, as a therapeutic experiment, it may be regarded as worthy of repetition in similar cases. But, as regards the pathology of this case, I think it is evident that both smell and taste were abolished independently of each other, and that we cannot account for the loss of taste by the loss of smell; nor can we say that the olfactory nerves were ruptured. It is also in the highest degree improbable that the loss of taste and smell could have resulted from simultaneous affection of the various nerves concerned in these functions; situated as they are so widely apart from each other, and bound up more or less with others not conjointly affected. But it might well happen that such a blow on the vertex as this man received would cause such injury to the subicular regions, by what is usually termed counterstroke, or by what Duret terms the *côte de soulèvement*, as to cause impairment or temporary abolition of the functional activity of the cerebral centres of taste and smell, which, as experiments on monkeys indicate, are here localised. Hence I would take this, and similar instances in which smell and taste proper are abolished by cranial injuries, as clinical corroboration of physiological experiment.

In respect to tactile sensation, though this form of sensibility is more frequently affected than any of the others by cerebral disease, it is extremely difficult, from a clinical standpoint only, to establish a distinct relation between this and certain cortical lesions, or localise the centres of tactile sensation. Motor paralysis and tactile anaesthesia are frequently associated with each other. But that the cerebral centres of motion and tactile sensation are distinct from each other, is evident from the fact that we may have the most complete motor paralysis without impairment of tactile sensation, as is the case with cortical lesions. And though motion is more or less impaired by the abolition of tactile sensation (by which motion is mainly guided), yet we have many instances in which the power of voluntary motion is retained notwithstanding the complete annihilation of tactile sensation, cutaneous or deep. There is, therefore, no organic fusion of the motor and tactile centres with each other, seeing that each may be affected independently of the other, and the two do not vary quantitatively with each other when they are conjointly affected.

The facts of cerebral disease in general, and of cerebral hemianæsthesia in particular, would seem to show that in respect to tactile sensation there is less bilateral representation in each hemisphere than as regards the other forms of sensibility. For, in central hemianæsthesia, tactile sensation is always most deeply affected, and may still remain greatly impaired after all the other forms of sensory impairment have disappeared. Hence, in the slighter forms of affection of the posterior third of the internal capsule, tactile sensation only may be impaired. Hence, also, with motor paralysis due to lesion of the anterior division of the internal capsule, we frequently get partial or temporary impairment of tactile sensation, owing to pressure on, or slight organic or functional derangement of the posterior or sensory fibres.

If, therefore, tactile sensibility be more unilaterally represented in each hemisphere—and this we might conclude from the remarkable power we possess of localising the seat of tactile impressions on any part of the body—we should naturally expect to find that lesions of the cortical centres of tactile sensation should be accompanied by symptoms of impairment or abolition of this sense. These centres, as I have already indicated, are situated in the hippocampal region. Lesions of this region are not, however, common; and I have not been able to find any cases of localised lesion of the hippocampus, except

those to which I have already alluded in connection with chronic epilepsy and insanity. But, as we have no record of the facts relating to the condition of tactile sensation in these cases, I must leave this question to be settled by future clinical investigation.

There are, however, some facts which would seem to indicate that lesions in the neighbourhood of the hippocampus do cause affection of tactile sensation, though doubt may be entertained as to whether the phenomena are dependent on direct affection of the hippocampus, or affection of the posterior front of the internal capsule, directly or indirectly.

Mr. Jonathan Hutchinson\* concludes, from his observations on cranial injuries, that contusion of the sphenoidal lobe more particularly, causes, along with partial motor paralysis, paralysis of tactile sensation on the opposite side of the body. As I have said, these effects may be attributed to injury of the sensory fibres of the internal capsule; but contusion of the sphenoidal lobe might also be interpreted as injury of the hippocampal region; and if the impairment of sensation in the cases described by Hutchinson were to be proved absolutely restricted to tactile sensation, we should have good grounds for considering the phenomena dependent on lesion of the cortical centres here situated. The definitive settlement, however, of these various points must be left to future research.

I have now brought under your notice a considerable number of facts, both positive and negative, in reference to the localisation of special sensory regions in the human brain; and though the positive clinical evidence is as yet comparatively scanty, and leaves much to be desired, I entertain the hope and belief that it will not long remain so. And I trust that those who rely more on the evidence of human pathology and the phenomena of disease than on the facts of experiment, even on the most human of the lower animals, and do not, therefore, share my own very decided convictions as to the localisation of special sensory regions, will take the facts I have adduced into careful consideration, and, when opportunities occur, investigate the conditions as to sensation in cerebral disease, with the accuracy and thoroughness which are much needed in order to clear up the doubts and obscurities which still surround this important question.

## CROUP: DIPHTHERIA: TRACHEOTOMY.†

By ROBERT L. BOWLES, M.D., Folkestone.

I HOPE I shall be excused by this society for so persistently bringing before it the well worn subjects of the heading of my paper. But, although these subjects have now for some years past anxiously engaged the attention of our profession, it does not appear, from the long and interesting correspondence in the *Lancet* during the year 1875, and the discussion at the Royal Medical and Chirurgical Society in the latter part of that year, that any decided opinion has been arrived at; still, the tendency of opinion (led chiefly by the authority of Bretonneau, Trousseau, Sir William Jenner, Dr. George Johnson, Dr. Semple, and others) is clearly in the direction of admitting that membranous croup is always diphtheria, *i.e.*, dependent only upon the specific contagium of diphtheria. Dr. West, whose excellent article on croup has always appeared to me to express the truth, in holding the opposite opinion, confesses that he is wavering; and there are many others in the same position as himself.

To no members of our profession is this matter of so much importance as to us who live in the provinces; especially to those of us who are in lone country districts. Croup is of more frequent occurrence in the country; and as many of us are compelled to act upon our own responsibility and act promptly, it is most desirable that we should be well supported by the authority of the leaders of our profession in any views we may feel ourselves compelled to adopt. Suppose, for example, one of us has lost a case of croup in a large country house—in the house of our best patient—that we had looked upon the case as catarrhal and inflammatory, and had treated it with tartar emetic or calomel, the family goes to town and is there told that "such theories are exploded, that the case was certainly one of diphtheria and ought to have been treated by wine, tincture of iron, or such like remedies, and that it was no wonder the child died". The happiness of the family is gone, and the reputation of the doctor with it. It well behoves us, therefore, to give anxious consideration to this question, and to think for ourselves; we have, I think, more opportunities of making accurate and complete investigations into the origin of our cases, than

† Read before the East Kent District of the South-Eastern Branch of the British Medical Association.

our London hospital physicians, and we ought, moreover, to press our experiences and our difficulties on those gentlemen, and prevent them, if there are doubts, from laying down dogmas, that will certainly influence the public and all those members of our profession who do not take the trouble to think for themselves. To this end, then, I now again contribute a paper on croup and tracheotomy.

CASE I.—In September 1874, I was requested by Mr. Hackney of Ilythe to see a case of diphtheria, with laryngeal complication; the child was in imminent danger of suffocation; tracheotomy was at once decided upon. There was a membranous patch on each tonsil, but no glandular complication, no swelling of the cellular tissue, and no history of contagion. Was this inflammatory croup or diphtheria? The operation was successful, and on the seventh day, the child appeared quite well, full of fun and mischief; on that day, the mother left it for a time, and for fun, during the mother's absence, the child threw off the flannel covering the tube; the next morning, signs of bronchitis appeared, and the child died in two days.

CASE II.—In January 1875, I was again called in by Mr. Hackney to see a case of what he, this time, called croup in a child which had taken cold, and which had not, so far as could be found, been subjected to the infection of diphtheria. It had commenced with catarrh, and bore the character of the old-fashioned croup; there was no glandular swelling or swelling of the cellular tissue. The case had been treated with tartar emetic and ipecacuanha, and was getting worse, but it was not thought justifiable to operate then; the child was to have a chance, as we had often seen cases of this nature yield to emetics. On looking into the throat, there was a small patch on one tonsil of closely adherent membrane; and then at once arose the terrible question, Is this croup, after all, or is it not diphtheria? Shall we treat the case with tincture of iron and wine, and the larynx with saturated solution of sulphate of copper; or shall we continue the antiphlogistic treatment of inflammatory croup? Yielding to authority and the tone of thought of the present day, we resolved upon the former course, contrary to the opinion we had formed before seeing the membranous patch. The next night, the child was worse, and but for tracheotomy would have died from suffocation. The child lived two days after the operation, and died from exhaustion with symptoms of bronchitis. In neither of these cases was Mr. Hackney able to obtain a *post mortem* examination.

CASE III.—On the evening of Saturday, January 8th, of the present year, I was requested, in Dr. Jervis's absence, to see a case of croup which he had been attending for four days. The history was that the child had a cold on the preceding Tuesday, running at the eyes and nose and slightly croupy cough. On Wednesday evening, the cough became more croupy. On Thursday, the cough was still more so, and the breathing slightly stridulous at times; the child was fourteen months old and teething, so the gums were lanced, and an ipecacuanha and squill mixture given, with instructions that, if the child became very croupy in the night, an emetic of ipecacuanha wine was to be given; the child did become croupy, and the emetic was administered. On Friday morning, the child was better and looking not much amiss; in the evening, croup as usual was worse; and on Saturday morning better, but the breathing perhaps more stridulous than on any preceding morning. A warm room, a steaming kettle, poultices, and other adjuvants, had been employed by Dr. Jervis from the first. On Saturday evening late, as I said before, I first saw the child, *i.e.*, four days from the commencement of the case. The croupy symptoms had become much worse and the breathing persistently stridulous, or rather, I would say, sibilant, notwithstanding the emetics. The child was prostrated by the vomiting. I carefully examined the throat, but could find no false membrane.

January 9th.—On Sunday morning, the sibilant breathing was evidently increased and not at all relieved by vomiting, which had occurred several times during the night; and now (8 A.M.) the child looked very faint and ill; the bowels had been purged three times; the motions were thin and very offensive, evidently from the medicines. Again I carefully examined for signs of diphtheria, but found no false membranes in the pharynx, and no swelling of the cervical glands or cellular tissue, or any history of contagion or bad drains connected with the illness. On the other hand, the child's nurse, the mother, and two servants, had had colds, all partaking of the laryngeal character, before the child was taken ill; and coincidentally with and subsequently to it, the grandfather and grandmother and lady's maid all had colds of a like nature. Colds were also prevalent in the town, but there was, to my knowledge, no diphtheria. Moreover, there were distinct dulness on percussion and fine rhonchus at the lower half of the right lung. The pulse was quick, but the child was so alarmed at my approach that I found it difficult to be accurate as to its number, and for the same reason I could make no satisfactory use of the ther-

mometer. I made up my mind, therefore, that I had to deal with inflammatory croup excited by catarrh; that doubtless false membrane already existed; and that, to save the child's life, tracheotomy would probably become necessary. Emetics were badly borne; but I ventured, in consequence of the presence of bronchopneumonia, to try five-minim doses of antimonial and ipecacuanha wines.

On Monday morning, January 10th, I found that even those small doses caused so much sickness and faintness that they were discontinued, and small doses of calomel were prescribed, in addition to mercurial inunction. The breathing was now very difficult and markedly diaphragmatic, whilst the intercostal spaces were depressed at each inspiration; the cough was dry, harsh, and husky; the voice thin and weak; the respiratory murmur feeble on the right side and accompanied with fine rhonchus and dulness on percussion. Late at night, Mr. Pollock arrived, and the operation of tracheotomy was anxiously discussed by him, Dr. Jervis (who had also returned), and myself. Just lately, there were some large moist *râles* to be heard in the trachea and larger bronchi, so it was thought we ought to give the child a chance of being saved the operation until the morning. Early the following morning, we found things just as they were, except that the trachea and bronchi had been cleared of their loose mucus. The child had not slept, but had suffered much from dyspnoea, and was constantly throwing itself about. It was put under the influence of a mixture of chloroform and ether; and at 9 A.M. the operation was leisurely performed by Mr. Pollock. Veins were pulled aside, and certainly less than thirty minims of blood were lost.

On the 12th, at 10 A.M., the child was comfortable and doing well, and took its food without difficulty. The skin was cool; respiration 40, pulse 160. 7 P.M.—He was sleeping quietly. Respiration 50; pulse 130, very weak. He coughed less and took but little food. He was ordered to take a teaspoonful of brandy every four hours.

January 13th. At 10 A.M., the child had taken its brandy and food well, and was much better in every respect. Pulse 140; skin cool.

January 14th. It was found that the child had taken two drachms of brandy every two hours, and was evidently slightly intoxicated, and had now been sick three times. It had had a dark greenish motion. The inunction was stopped, and the brandy was diminished to thirty minims. As dried mucus collected in the tube, the flannel was kept more moist.

January 15th and 16th. All went well, with the exception of a vomiting attack. Skin cool; pulse 124; respirations 40. He coughed more, and brought up a quantity of sticky brownish muco-purulent secretion. The right lung was much clearer; the *râles* were to be heard, but no tubular breathing.

On the 17th, 18th, and 19th, he was doing well. He looked pale and weak; coughed less. He took egg and bread and butter.

On the 20th, the tube was removed; but almost no air passed by the larynx. Violent coughing and struggling commenced. The child could get no air by the wound or larynx; for during inspiration the sides of the wound were sucked together. On expiration, false membrane was seen flapping through the wound. A fenestrated tube was immediately inserted, but with some difficulty, in consequence of its sides (it was a bivalve) catching on the sides of the trachea, pressing it backwards, and thus nearly suffocating the child. During the violent coughing and struggling, much muco-pus was expectorated. In the evening, the child was quietly asleep, breathing almost entirely by the nose. Respirations 32.

On the 22nd, the child seemed very uneasy. Although there was no dyspnoea, the tube was found to be stopped up with pus; it was removed, and its removal was followed by about half a drachm of pus and a little blood.\* No air passed by the wound.

January 25th. The wound was healed; the child convalescent. The urine was examined for albumen, but there was none.

Neither in these cases, nor in two other successful cases of tracheotomy for membranous croup which I formerly brought before this society, was there any secondary paralysis.

If I might venture, gentlemen, to offer a suggestion, I would say that it would be desirable as much as possible that the discussion, which I hope will result from the reading of the foregoing cases, should be divided into two portions: 1. Whether they were cases excited by the specific contagium of diphtheria, or not; and 2. The merits of the operation of tracheotomy. I would more especially draw your attention to the first portion, which is almost daily the subject of our anxious consideration, and upon which we have to take prompt and decided action, resulting in good or evil of the utmost gravity, according as that action is right or wrong. In reference to this, I

\* It is probable that this tube had not been in the trachea, but in the cellular tissue in front, and that what air did come by the tube was by the fenestra.

would just remark upon the great danger of stamping everything as diphtheria where there is found fibrinous exudation. We know that it is found as a result of scald from hot water, and I have seen a throat after the removal of tonsils that I could not have distinguished from diphtheria.

Three years ago, my coachman lost his voice, and I found a thick tough exudation over the whole of the posterior wall of the larynx. There had been bad measles in the house in which he lodged, and bad drainage. There was no glandular enlargement or puffing of the cellular tissue. I believed it to be diphtheria, and treated it as such; but it was bad for many weeks, and only yielded to iodide of potassium or warm weather. There was *no history whatever of syphilis*. The next winter, it was just in the same condition; and this year again it was like the two preceding winters, although each time he was living in different houses and under different circumstances, and no other members of his family had suffered in a similar manner. My coachman attributed it, and I now think with reason, to the exposure to cold, as he is never in any way ill excepting in the bad weather of winter.

In bad scarlatina, in bad measles, and at the end of many exhausting diseases, membranous exudations are to be found; and I think it very probable that of late years many cases have been attributed to the specific contagion of diphtheria, which really owned no such origin.

## MALARIAL FEVER AT ROME.

By LAUHLAN AITKEN, M.D., Rome.

THE existence of a malarial element in the climate of Rome is so generally admitted, that it is quite unnecessary to enter into the history of the subject, to point out the foci of infection in the Campagna, to discuss the different effects of the poison, or even to mention the many varieties of malarial fever which authors describe. In this paper, I shall only deal with the effects of the malaria on unacclimatised strangers, English or American, who have been under my care. So dormant is the poison during the winter and spring months, that acclimatised members of the nationalities mentioned, who can afford to live well and to reside in a healthy quarter, are, so far as my six years' experience goes, never affected; but visitors, who are careless of consequences and heedless of the ordinary warnings, often overwork themselves in sight-seeing, become heated in the sun, and stand for hours in museums, galleries, and churches, exhausting their nervous systems, or expose themselves more directly on the Campagna, or even within the walls of the city, to a chill which results in an attack of so-called Roman fever. What this fever is the residents are often very puzzled to know, as strangers include under the generic term all kinds of ailments from a simple cold to a severe enteric fever; and it is sufficient to fall ill in Rome to be credited everywhere with being a victim of that vague disease. The result is naturally a wide divergence of views on the subject, and an alarm proportionate to the amount of confusion created. *Omne ignotum pro terribili* is the idea of all who speak of Roman fever.

That the malarial poison does produce, more particularly in the unacclimatised, a type of fever which can scarcely be classed under any such heading as intermittent or remittent, is certain. To this form the name "subcontinuous typhoid" has been given by Professor Baccelli of Rome. The term, fortunately, has not as yet become widely known; for, though the type of fever may be regarded as subcontinuous, yet, in whatever sense we take the word typhoid, the epithet is misapplied. If we regard it as used to express the group of symptoms called typhoid, or the typhoid state, my experience contradicts such an use, as none of the forty-five cases I have treated throughout have presented those symptoms which British physicians at least class under this heading. On the other hand, it is evident that Baccelli does not look on this fever as the product of the union of the malarial poison with that of decomposing excrementitious matter, as he carefully distinguishes his subcontinued typhoid from true ileo-typhus (enteric fever). Indeed, Baccelli seems to contradict himself in his lectures on the subject, as in one part he says that "the two morbid entities—the typhoid and malarial poisons—each losing its autonomy, become so fused together, but with the malarial predominating, that they give rise to the special type—subcontinuous typhoid"; while in other pages of the same pamphlet he asserts that "the subcontinuous typhoid is a fever resulting from malarial infection, pernicious as to type"; and again, "that, when a subcontinuous typhoid breaks out, every other morbid element, rheumatic, bilious, or typhoid, becomes subordinate to the malarial". It is, therefore, difficult to determine in what exact sense Baccelli uses the term typhoid; and I prefer to regard those

fevers as truly malarial, though presenting a remarkably continued course.\* I am far from denying the occurrence of the combined type of fever which may appropriately be called typho-malarial. Indeed, I have treated such cases; but, as might be expected, the more severe poison very soon predominates, and the bowel-symptoms and eruption make the diagnosis of an enteric fever clear.

*Etiology.*—The fever to be described results, then, from malarial poisoning; the predisposing causes being, in the cases I have seen, unacclimatisation; lowered vitality from anxiety of mind, from chronic diseases, or from previous acute complaints, particularly the malarial; pregnancy and the puerperal state; or a combination of some of these; while the exciting cause in every instance I have known has been a direct chill when the body was overheated, or its power of resisting cold diminished by any such causes as have just been mentioned, or by exposure during the night, when the heat of the body is naturally lower. A few lines from my case-books will illustrate this.

E. P., a young lady aged 22, goes to an evening party after a fatiguing day's sight-seeing; dances until well on in the morning; stands, when perspiring, at the door awaiting her carriage; gets a chill, and the next day is laid up.

J. G., a gentleman aged 28, has a hard day's work after the bounds on the Campagna, arrives much overheated at one of the gates after sunset, dismounts there, and drives to his hotel in an open cab without putting on a greatcoat. Two days afterwards, he shivers, and he has a somewhat prolonged fever.

S. S., a young lady aged 17, just convalescing from bronchitis, sits at an open window one cold afternoon in December, gets chilled, and has the most severe attack yet treated by me.

The Rev. Mr. D., aged 30, reading with some Oxford students, has one of the headaches to which he is liable; and, after a long heating walk to get rid of it, he sits down about sunset on the grass outside one of the gates, and gets what proves to be a mild attack.

D. W., aged 19, a young gentleman, rising one morning in December with a stitch in his side—dry pleurisy it turns out to be—takes his cold bath as usual, does not react at all, and has also a mild attack, which masks the pleuritic symptoms entirely for more than ten days.

An exactly similar account of the origin of the complaint might be given in nearly all the forty to fifty cases mentioned.

It is certain that the young are much oftener the victims than those advanced in life, which partly arises from their greater imprudence, and partly from their greater predisposition to contract fevers. So much is this the case that, though quite as many, if not more, elderly people come to Rome, yet among my cases four only have been over forty years of age. So far as sex is concerned, the numbers have been pretty equal; and the severity of the attack has apparently depended more on the previous state of the patient than on the fact of the chill having occurred within or without the walls of the city.

*Incubation.*—This could not be determined in every case; but, in nearly all in which the time of getting the chill was definitely fixed, it did not extend over two or three days. In several, the first symptom—more or less decided shivering—began within a few hours. In the young lady mentioned, in whom the attack followed a bronchitis, the temperature was 102.2 deg. within seven hours from the time of the chill. In another young lady, the shivering and headache began within a few hours from the time at which she had felt cold when sitting in a draught at an afternoon tea. In one gentleman (over forty), the incubation-stage seemed much longer. He was ill for about eight days with indefinite symptoms; loss of appetite; furred tongue; urine laden with lithates; evening headache and disturbed sleep, but no rise of temperature—pointing, as I supposed, to functional liver-disorder, but quite unrelieved by the treatment adopted; when he was sent to Albano, where he became worse instead of better, and from which he returned after a few days with a well-developed attack. At what exact period of his stay at Albano the fever first showed itself, is uncertain. It may be objected, that the symptoms previous to the appearance of the fever did not necessarily constitute the incubation-stage; but I incline to think they did, from the non-specific treatment adopted doing no good at all. In the other three cases of elderly people being affected, I was unable to fix the date of the chill. Indeed, two of the patients had been under the care of other physicians before I was sent for; and in the fourth I could not definitely determine the length of the incubation, which probably varies with the age and power of resistance of the patient, as well as with the dose of the poison. General languor, an inclination to sigh and yawn, insomnia, aching pains in the muscles, and loss of appetite, are symptoms common to the incubation-period of all forms of fever.

\* Although venturing to differ from Professor Baccelli as to the name of the fever, I would here express my appreciation of the great value of his communications on the subject.

**Symptoms.**—The fever begins usually with more or less decided shivering, but never, in my experience, to the extent of the chattering of the teeth, blueness of the lips and face, and shaking of the whole body, seen in an ague-fit. Sometimes there is only the feeling of cold water running down the back, and occasionally nothing more than a little shuddering or the sensation of goose-skin. In one young lady, aged 24, a prolonged syncopal attack was the first symptom, recurring more or less every day for about ten days at the same hour. This daily recurring faintness I saw in another young lady, in whom the fever began in the regular way with shivering. Neither of the patients had ever been subject to fainting fits, which obviously took the place of the cold stage of an ague. It may begin as a genuine intermittent, and take the subcontinued form. Baccelli asserts that it often does so, but I have never seen it amongst the strangers, though I have known it terminate both as a quotidian and a tertian intermittent. Headache is invariably present in the beginning of the attack, always frontal and quite distinguishable from the neuralgia of the ophthalmic divisions of the fifth nerve, supraorbital and ocular, which pressure on the supra-orbital notch and on the eyeball, and the attempt to rotate the eyes, often prove to exist. Occasionally, the neuralgia is occipital; and in one old lady, aged 65, violent unilateral neuralgia of the branches of the fifth and of the cervico-occipital nerves, of an intermittent character, constantly reappeared during a somewhat prolonged attack of the fever. The eyes are generally congested at the beginning, while, during the fever, the conjunctivæ become yellowish, as Baccelli also observes.

Few of the nerve-symptoms were prominent, either in the beginning or throughout the complaint. Delirium was rare and transitory, except in my two youngest patients, aged 14 and 17 respectively. Slight confusion of ideas, marked listlessness, and sleeplessness, were common to all, but no deafness apart from that caused by drugs.

**Temperature.**—The thermometer shows a sudden and rapid rise of temperature, after the initial symptoms: from 102 deg. to 105 deg., being very commonly found quite early in the complaint, within a few hours from the shivering, for instance; and until means are taken to diminish it, either by cold applications or by the use of quinine, this increase of heat virtually remains unchanged. During the progress of the fever, however, there seem to be rapid fluctuations of temperature several times in the twenty-four hours, and the remissions are not invariably in the morning. Indeed, the temperature in several of my patients has been lower in the evening than in the morning, and that for many days consecutively; but, as all my cases have been treated with antipyretics—quinine, usually in large doses—the charts only indicate the course of the fever thus modified.

*Case of E. P., an English lady, aged 42. First seen on the evening of the second day of the fever. The case was of average severity, and there were no complications. She was treated throughout with quinine, but not quite in such large doses as usual.*

Days.	M.	F.	Days.	M.	F.

7	99.5	104.0	16	98.7	98.7
8	101.0	102.1	17	98.5	100.5
9	101.0	102.1			

A typical case ought to have the temperature indicated every few hours, but in private practice that is nearly impossible.

**Circulatory System.**—The circulation never seems so rapid as the rise of temperature would lead us to expect. Even quite at the beginning of the attack, the pulse is seldom more than 100 per minute, and, as soon as antipyretics are absorbed, it falls, so that it is quite usual to find the heart beating only from 70 to 90, with a temperature at from 101 deg. to 104 deg. It is nearly always quicker in the evening than in the morning, but not more so proportionately than in health. Feebleness, irregularity, and intermittency have often been observed after the

fever had gone on some time. Occasionally, there is congestion of the cutaneous vesicles of the face, neck, chest, and abdomen; and I have seen limited erythematous patches, in two or three cases, over the same parts; but there is no eruption characteristic of the complaint.

**Sweating** is a nearly constant symptom. As a rule, it has been moderate in amount and has come on in the early morning hours, but very often it has appeared at other times without any apparent cause. In some patients, it has been a symptom throughout; while in others, it has first shown itself towards the end of the complaint. In only a very few has it been so excessive as to require the use of waterproof sheeting to protect the bedding.

**Digestive System.**—The tongue from the beginning is covered with a thick white fur. I have notes of the occasional appearance of red prominent papillæ at the tip, but never of its being red all over, nor of cracks or fissures on it at any time, nor of any hæmorrhage from the tongue or gums. In one or two of the younger patients, there has been epistaxis, and the lips have bled, but not to any extent. When the patient improves, the white coating begins to disappear from the tip and edges first. The mouth is rarely dry, and patients do not complain much of thirst. The appetite is lost, but nausea and vomiting are unfrequent; though, in one severe case, vomiting was the leading symptom in the beginning of the attack. The liver and spleen are both enlarged. The former organ is congested, and Baccelli believes there is probably catarrh of the bile-ducts in many cases. I have, however, never seen jaundice; and, while the conjunctiva often becomes yellow during the progress of the complaint, the presence of bile in the urine has not been detected. The spleen is invariably somewhat larger than usual, but it seems to yield readily to the action of quinine, as only in one case did it assume great dimensions and project into the epigastrium. It was then very tender to the touch, and pressure on it excited severe retching. But though there may be exceptional cases, the rule seems to be that the spleen does not enlarge to the extent described by writers on intermittent and remittent fevers. In microscopical examinations of the blood, no excess of leucocytes has been found, or any of the pigment-particles which other observers have noticed. In the bowels there is little noteworthy. Constipation seems the rule, necessitating purgatives, and sometimes very strong purgatives. When there has been diarrhoea, it has been of a bilious character; more bile escaping from the congested liver, or the reabsorption in the bowels being more sluggish. No pea-soup stools occur, nor general or localised tenderness on pressure over any part of the abdomen except the epigastrium, or over the liver or spleen if enlarged. Occasionally there is slight meteorismus, but, as Baccelli notices too, it is never persistent. At the beginning, the urine is acid, scanty, of high specific gravity, and filled with urates. As soon as treatment takes effect, it becomes neutral or alkaline, clear, and with only slight deposit of epithelium and of phosphates, but the chief microscopic feature is the nearly constant presence of pigment-particles. Analyses of urea have been made, but are not yet worth reporting. Albumen has scarcely ever been found; a fact in marked contrast to my observations in enteric fever here.

**Course.**—This fever seems to have no definite duration. The shortest of my cases—a gentleman aged 39—was apyretic on the seventh day, and continued so; but I suspect he had fever two days before I was sent for. The longest case lasted thirty-six days; but this was due to a relapse, as the patient, a young lady, was without fever from the seventeenth to the twenty-second day. The termination of the case is often indicated by the gradual cleaning of the tongue, by the fever assuming a true remittent or intermittent type, and by an increase of the perspiration in the morning hours; and if this be excessive, the temperature has been frequently found subnormal at all hours of the day. Very rarely do anything like critical deposits occur in the urine.

**Complications.**—Two patients had unilateral pleurisy with considerable effusion, which, however, disappeared quickly. One—a lady aged 51—had pleurisy and endocarditis, and only slowly recovered. One patient had bronchitis, and one thrombosis of the left leg. None of my own patients had any other complication; but one lady, aged 28, whom I attended as consulting physician ten days after the fever began, miscarried at the eighth month, and died from *post partum* hæmorrhage. Baccelli describes complicated cases as special forms of the fever—the bilious, the rheumatic, the pneumonic, etc.—but I know nothing of these.

**Prognosis.**—None of the forty-five patients treated throughout by myself died; and only three—the two youngest treated and the lady who had the complication with pleurisy and endocarditis—were very dangerously ill. One young gentleman, aged 18, whose temperature was 102.4 deg., insisted on getting up on the tenth day, and went out for a walk. He repeated this on two subsequent days, was none the worse, and was apyretic on the fourteenth day. Some of the patients

had been delicate, and were travelling by the advice of physicians, but none had any well defined chronic malady. In uncomplicated cases, therefore, in average health, the prognosis is very favourable.

**Diagnosis.**—The only other fever with which this could easily be confounded is a mild enteric fever, as they certainly have some features in common; but the short incubation, and the rapid rise of temperature even to 104 deg. soon after a chill, seem almost absolutely to exclude the idea of sewage-poisoning. The response of the fever to treatment, its indefinite duration, and the total absence of any eruption like that of enteric fever, with the negative character of the bowel-symptoms, seem quite as certainly to disprove the existence of any specific intestinal glandular lesions, even if the *post mortem* examinations made by others were not quite satisfactory on the point, hyperæmia of the Peyerian patches being the utmost that is found; while the frequent termination of the cases as remittents, or even as genuine quotidian and tertian intermittents, seems quite as eloquently to prove its origin from malaria alone. Enteric fever, indeed, is as marked in its features in Rome as in London. I have lost five out of fifteen cases, two from bowel-hæmorrhage; and the abdominal symptoms have been prominent in all. It is obviously essential to distinguish the two fevers, as an early and energetic specific treatment undoubtedly lessens the severity and shortens the duration of the malarial form; whereas, if neglected in the beginning, it becomes rebellious to remedies and very tedious in its course. The prognosis, too, is very different, and it is probably from the two fevers being constantly confounded together that Rome has acquired its unenviable reputation for typhoid; whereas, as I have shown in the *BRITISH MEDICAL JOURNAL* for September 16th, 1876, fewer cases of enteric fever originate in Rome in proportion to population than in any other large continental city.

The subcontinued type of the fever described, and the rapid variations of the temperature, distinguish it clearly from the malarial remittents of British authors; but it frequently passes into a remittent fever. For other fevers it could not well be mistaken.

**Treatment.**—When the ordinary antipyretic mixtures have been given in the beginning of those fevers, they have had no appreciable effect, except perhaps in making the pulse a little slower. A good purge is usually given, the much abused calomel very often, and then quinine in some form. At first, it was given in small and divided doses: two grains every two hours, or three to four grains every four hours. But most of the patients have had the drug in one or two large doses in the forenoon, or at least before 2 P.M., if possible, although the thermometer too often fails to show a remission at that time. Unless the patient's objections are insurmountable, the quinine is given in solution. Formerly, it was combined with bromide of potassium, or alkaline mixtures were given at the same time. Now, I almost always use the hydrobromic acid, as recommended by Dr. Milner Fothergill. Both the bromide and hydrobromic acid counteract to a certain extent the unpleasant effects of large doses of quinine; but the hydrobromic acid is much the more effectual of the two. The headache, neuralgia, malaise, and general aching pains either disappear altogether or are much alleviated, as soon as the patient comes under the influence of the quinine. It notably slackens the pulse and lowers the temperature. Fifteen grains will bring the pulse down from five to ten beats, and the temperature from one to three degrees, within two hours of its administration in solution. The average amount given in the beginning is from fifteen to thirty grains daily. I have found no patient intolerant of the remedy, even when their repugnance to it has been based on the opinions of the leading physicians of Great Britain and America. Most of them, after the first doses, are too sensible of the benefit derived to doubt the fact that the disease indicates the means of cure. If the patient will not take it in solution, it is given as a powder in a rice-wafer, followed by some drops of nitric or hydrochloric acid. Quinine enemata have rarely been used, and subcutaneous injections of the drug were necessitated in only one case by constant sickness, and by the young patient not tolerating the enema-syringe. Cold applications, too, are always used. Frequent cold sponging of the body, the ice-bag to the forehead and back of the head, iced compresses over the spleen, are all useful. Tepid baths rapidly reduced in temperature were required in a boy aged 14, who was very delirious. They were given eight or ten times with excellent results. The diet is restricted to fluids; and stimulants are seldom needed, except during convalescence. Salicylate of soda has been given in doses varying from thirty to ninety grains at short intervals; and, in the forenoon hours, if practicable, sixty to ninety grains have nearly the same power in reducing temperature as fifteen or twenty grains of quinine, but the effect seems to disappear more rapidly. Salicin, tincture of eucalyptus, and Warburg's tincture, have also been used; but little reliance is placed on anything but quinine.

**Recurrence.**—It is uncertain whether this type of malarial fever tends

to recur. In those patients whose history, subsequent to the fever, is known, it has not done so. If it did, it would probably be as some variety of intermittent fever. No injurious sequelæ have come under my notice.

**Frequency of Occurrence among Visitors.**—It is obviously impossible for any one physician to give an exact idea on this point. The fever goes by so many different names—Roman, bilious, nervous, gastric, typhoid—that it is very difficult to know when it is the type described that is meant. Besides, there are no proper data for calculating the number of visitors in a season.

## CLINICAL MEMORANDA.

### REMARKS ON SCARLATINOID ERUPTION IN THE AGUISH DISORDERS OF CHILDREN.

IN Dr. Cheadle's interesting paper on the occurrence of ague in young children in London (*BRITISH MEDICAL JOURNAL*, April 13th, 1878, p. 523), he remarks that he had never previously observed a general scarlatinoïd eruption in young children, nor can discover any instance of its occurrence on record. I have never witnessed so general an eruption as existed in his first case; but I have long been aware that cutaneous hyperæmias occur in aguish disorders, such as I have termed malarioïd remittent, having more or less resemblance to scarlatinal rash; and I referred to them in my work as roseolous. In the case mentioned at page 765, the child, aged 3½, became red all over, legs, face, and all, two or three times a day. She had several pyrexial attacks in the twenty-four hours, and I found her temperature in one of them to be 102.2. In the following case, which occurred to me in 1869, the cutaneous hyperæmia was usually a less striking feature than the anæmia; but both phenomena were well marked, and are both attributable to the same cause, just as the cold and hot stages of a common ague are.

E. B., aged 3, admitted October 14th with herpes of the face, was described as having suffered for one or two years with seizures occurring two or three times a day, in which she turned "deadly white"—"as white as a child laid out for dead". She was also very restless at night, very feverish, and "burned" very much: Usually the burning affected the hands; but on November 24th her chest and face were quite red, as in scarlatina, for three hours; and about the middle of December she was one day quite prostrate and scarlet all over, slept all day until the evening, then woke up, lost her redness, and appeared quite well. Beside the vasa spasm and paresis, she had fits of panting and difficulty of breathing, lasting several hours or even a whole day. These were probably analogous attacks of bronchial spasm. In general condition, she was languid and drooping, and her flesh was flabby. With citrate of iron and quinine, five grains three times a day, administered for three months, she improved steadily, and completely recovered. In such a case as this, the diagnosis of malarioïd remittent was sufficiently plain; and usually the rash is, I think, more suggestive of roseola than scarlet fever. Yet, in some cases, for a time doubt may prevail, especially should there happen to be some sore-throat.

I have no note as to whether this child had ever resided in a malarious district; but that London is capable of giving rise to aguish disorder is, I hold, certain. In addition to the evidence given in my work at page 761, I may mention the case of a student who had never had ague, or been in the way of it, before he came to London, where he had several attacks, and could not get rid of it until he left. Another case was that of a young lady who always lived in a high dry locality, except that she spent one night at Stratford near London. She had well-marked ague for three or four weeks, and felt its effects long afterwards. Jaccoud's experience of Paris is quite similar.

C. HANDFIELD JONES, M.B.

### STRAPPING THE CHEST IN THE TREATMENT OF CHRONIC PULMONARY CONSUMPTION.

IN private practice, I have lately had a case of pulmonary consumption in which great benefit was produced by strapping the upper part of the chest. The patient was a female aged 33, the wife of a tradesman; she had had one child. The disease apparently began, as chronic pneumonia of the apex, in February 1877; and when I was first consulted, exactly a year afterwards, there was sufficient evidence of a cavity at the top of each lung, and the constitutional symptoms were very grave. The case was clearly hopeless; but at first there was a marked improvement from the internal use of the hypophosphite of lime, and from the external application of strips of soap-plaster, ex-

tending three inches below the clavicle in front to halfway down the chest behind. The plaster was put on with considerable firmness, and each strip was about an inch broad. My patient spoke gratefully of the comfort and support which this simple plan afforded her, and the cough was strikingly lessened. Unfortunately, the cold weather at the end of March caused a sudden exacerbation of disease, and death ensued after a short period of dyspnoea and other suffering.

The method of strapping the chest in various pulmonary diseases was recommended by Dr. F. T. Roberts some years ago in the *Practitioner*, and again in his *Handbook of the Theory and Practice of Medicine*. He applies both vertical and transverse pieces of plaster, some of the latter being placed horizontally and others obliquely; and if there be any marked depressions above or below the clavicle, he fixes pads of cotton-wool in the hollows beneath the plasters. For obvious reasons, the transverse strips are not so easy to apply in the female; and my patient was quite contented with the vertical strips, as she found a single cross strip above the breast apt to get wrinkled and uncomfortable.

Dr. Roberts has explained the objects to be aimed at by this treatment; the chief of which are the keeping of diseased structures in as quiescent a state as possible, and, by a limitation of the chest-movements, it is attempted to check an overactive circulation. One result (not noticed by Dr. Roberts) may be this: by supporting weak ribs and weak intercostal muscles, the chest-walls are kept more together, and therefore less work is required of the ordinary muscles of respiration; and everything which economises muscular force must help to maintain the patient's strength.

JOHN K. SPENDER, M.D.Lond., Bath.

#### NOTES ON A CASE OF LARDACEOUS DISEASE.

PERHAPS the following case may be deemed interesting; firstly, for the fulfilment of the law of its course as well as the law of its onset; secondly, for the side-issues raised (a) as to its origin in nerve-change, or otherwise; (b) as to its bearing on prognosis; and (c) as to the particular part played by the non-expectorated lung-discharges; and thirdly, it is interesting from the fact that until within three weeks of death, the patient never or rarely owned to any feeling of illness. At twelve years of age, I. T., whose mother died in decline, was a fair, dreamy-looking, blue-eyed girl, with a clear delicate skin and fine light hair. She came under notice in 1874. In June 1875, she suffered from an ulcer of the cornea, with much tearing and fear of light; but, aided by atropine, warm fomentations and bandages, etc., the eye got well again, carrying but little trace of the past mischief. In July 1876, the top of the left lung broke down; and for about three months, a destructive inflammation never left that part; the thermometer registering, whenever placed under the tongue, temperatures varying from 99 deg. Fahr. to over 103 deg. Fahr. There were, moreover, during this time, attacks of diarrhoea, night-sweats, a pulse often of an almost empty vessel, and nights disturbed by cough. The left chest plainly lagged behind its fellow in breathing; the part under the collar-bone looked fallen in; and gave out, on tapping, the usual muffled note. If, as a set-off against these bad signs, we put that for the greater part of the three months she took a good deal of food, and also that, in August, she walked two miles, we have grounds enough for a prognosis. In September, the temperature being 102 deg. Fahr., I told one who was interested in the case that it was not at all likely the girl would live to see Christmas-day. Soon after this, the temperature began to fall, and flesh and strength to be gained; and many weeks before Christmas 1876, all active mischief was gone. One point I have not named: she never spat after coughing unless she was made to. Of drugs, she took hypophosphite of soda for a time, bark and cod-liver oil the whole time, and also iron for a time. She had a morphia and hydrocyanic acid linctus to take when required. She was allowed plenty of new milk and plain food; but no stimulants, because they did not agree with her. Through the whole of 1877, she did not require any attendance, though she sometimes had a bottle of her linctus. In January 1878, she came to me with shingles; and this set me wondering whether any kinship ran through the shingles, the ulcerated cornea, and the ulcerated lung; whether they were but different expressions of a like faulty nerve-influence; for changes in the highest of organised tissues would seem likely to be an early factor in the sum of those changes which make for an early general death. But this by the way. A fortnight afterwards, her cough began to trouble her again. She passed a great deal of urine, both in the day and in the night. Her legs, too, had taken to swelling; so I was called in. I found her up and about. The face was a little puffed, but her cheeks wore the look of health. The legs, always rather thick, were swollen. On listening with the stetho-

scope over the dull upper part of the left lung, and asking her to say "One, two", the somewhat punch-like "One, two", was heard, followed by "Whiff, whiff", like a sort of whispered echo, first "One, two", then "Whiff, whiff". There were creaking sounds at the apex of the right lung. Temperature 99 deg. Fahr. The urine coagulated to about one-fourth. The microscope showed several long, wide, straight tube-cases, and a few pus-corpuscles. For the next month, or at least up to March 7th, she continued to get about; and the chief troubles she had to fight against were: dropsy, which was met by iron, sulphate of potash, acetate of potash, and acetate of ammonia; diarrhoea, which was met by leaving off the sulphate and acetate of potash; sickness, which was met by a bismuth mixture; cough, which was met by a morphia linctus; and weakness, which was met by port wine, animal food, and new milk. But on March 7th, 1878, the urine became scanty; and two wineglassfuls of decoction of scopolarium morning and night, with a quinine mixture and an iron mixture given alternately at two-hour intervals through the day, failed to mend matters long. By March 20th, no urine was passed except what might escape when the bowels were moved. On the 21st, there was a slight convulsion; and from this time the dropsy ceased to trouble, while death threatened by a diarrhoea with blood, on the one hand; and by fits and head symptoms, on the other. The diarrhoea was checked by sulphate of copper, and the head-symptoms were met by a milk-diet; but she died on March 30th.

S. WILSON HOPE, Petworth, Sussex.

#### ARTIFICIAL RESPIRATION IN SUSPENDED ANIMATION.

I OBSERVE that this subject is just now engaging the attention of the profession pretty extensively, owing to a new method of procedure being advocated. This method is exactly the mode of procedure I have pursued for the last eighteen years in the case of infants born in a state of suspended animation. I may have been remiss in not having placed my course of action before the profession long since; but, as I commenced these tactics without any consideration on my part, and without laying out for myself any special line of procedure, I thought it more than likely that very many, if not all, of my professional brethren would be found to practise similar methods, and that hence what to me might seem original would turn out to be in general practice. I have not had to do with suspended animation in the adult, so do not know if I should have resorted to similar tactics in the more mature being. For the time above indicated, on a child being born in this state, I have been in the habit, both before and after the severance of the umbilical cord, of placing one hand on each side of the chest and using steady gentle pressure, thus approximating the sides of the thorax sufficiently to allow considerable expansion on the removal of my hands (which I do just then), from the elasticity of the parts in returning to their natural position. In a few cases where I have found the resumption of the natural position slow, I have used a little gentle pressure over the sternum, which invariably sends out the ribs at once. By repeating this with sufficient frequency, in imitation of the process of breathing in the young infant, together with clearing out the mouth and fauces, and looking after the position of the tongue, also with a little douche of cold water now and then, I have, I believe, been rewarded with more than usual success.

I do not recollect having lost a single case in which there was the least sign of animation, although I have been asked to desist by professional nurses and relatives. In some of these cases, while I clean out the fauces and change the position of the tongue or body with one hand, I carry on the respiration with the other by using the counter-pressure of my thumb, grasping, as it were, the front and sides of the thorax in my hand and tightening or relaxing my grasp as required, just as one would do with an elastic air-ball.

I hope these few short remarks on my mode of procedure in these cases will not be considered obtrusive, and that they will assist in establishing what, I believe, will be found a better mode of procedure in these cases.

JOHN MARTIN, L.K.Q.C.P.I., L.R.C.S.I.,  
Senior Medical Attendant, Belfast Dispensary.

WE often receive queries as to the subject of preparation for the Public Health Service, which has now become an important career for medical men. We are requested to mention that a course of lectures by Dr. W. H. Corfield on Public Health will commence on Thursday next, at 4 P.M.; and that it will be especially suited for those who are intending to compete for State Medicine certificates. We may also state that the hygienic laboratory of University College is open for the necessary practical work, and that two of the laboratory students have lately gained certificates in sanitary science.

## GENERAL COUNCIL

OF

## MEDICAL EDUCATION AND REGISTRATION.

SESSION, 1878.

Tuesday, April 16th.

Dr. ACLAND, President, took the chair at 2 P.M.

*Deputation from the Obstetrical Society.*—In accordance with a resolution passed at the Council's meeting on April 12th, 1878, a deputation from the Obstetrical Society attended, composed of Dr. West (President), Dr. Barnes, Dr. Priestley, Dr. Aveling, Dr. John Williams, and Dr. Murray. Dr. WEST explained the views of the Society, and enlarged on the scheme proposed by it.

The following are the principal provisions of the scheme.

1. No woman, unless her name is placed on the Register, shall hereafter be allowed to call herself a duly qualified, legally qualified, or registered midwife; or to use any name, addition, or description implying that she is duly registered; and every woman so doing shall, upon a summary conviction for any such offence, pay a sum not exceeding £5. No woman shall be entitled to recover any charge in any court of law for attendance or services as a midwife, unless she shall prove at the trial that she is duly registered.—2. All women at present practising as midwives may be placed on the Register on production of a certificate of moral character from some magistrate, clergyman, or other minister of religion in the town, parish, or hamlet in which she lives, and of a certificate of competence from some registered medical practitioner, personally acquainted with her, on payment of five shillings for the expenses of registration. (Fraudulent registration to be a misdemeanor, punishable with imprisonment for a term not exceeding twelve months.)—3. All women placed on the Register shall receive a numbered certificate, corresponding to the number on the Register; the possession of which shall alone render them eligible for holding any public appointment as midwives.—4. A register, containing particulars of name, age, civil state, and residence of each midwife, with a number corresponding to that on each certificate, shall be kept by the Senior Medical Officer of Health in the City of London, and in each assize town throughout England and Wales (with certain exceptions).—5. Each district registrar shall make an annual return to the Registrar of the General Medical Council of the names and addresses of registered midwives in his district, and also of the names and addresses of those registered each year; and it shall be the duty of the Registrar of the General Medical Council to keep such register, and to render it accessible to all applicants. Any registered midwife may, on the payment of five shillings to the registrar of the district in which she lives, receive from him a certificate which shall enable her to have her name transferred to the register of the district to which she removes.—6. The registration towns in each district shall also be the towns at which examinations of midwives shall be held at least twice in the year.—7. All complaints of malpraxis, or of immorality in the exercise of her calling, shall be made to the registrar of the district in which the offence is alleged to have been committed; and he shall thereupon summon the members of the examining board of such district to consider the complaint; and it shall be competent for them to send a report with their recommendation on the subject to the General Medical Council, who may, if they think fit, suspend her for a time, or remove her name from the Register. Any midwife continuing to call herself a duly qualified, or legally qualified, or registered midwife during the time of her suspension, or after her name has been removed from the Register, shall be liable to such punishment as is referred to in Regulation 1. If any registered midwife shall be convicted in England or Wales of any felony or misdemeanor, it shall be the duty of the district registrar to communicate the fact forthwith to the General Medical Council, which shall cause her name to be removed from the Register, and send her notice of such removal.—8. The certificate conveys no right to the midwife to practise, or to be registered, as a medical practitioner. Any registrar who shall wilfully make, or cause to be made, any falsification in any matter relating to the Register, shall be deemed guilty of a misdemeanor.—9. Every woman applying for admission to examination in order to be placed on the Register as a midwife, must bring proof of being not less than twenty-one years of age, and of good moral character, as certified by a magistrate, or by a clergyman, or by some other minister of religion, in the town, parish, or hamlet in which she lives.—10. She must satisfy the examiners that she can read

writing as well as printing easily; that she can write legibly; and that she can do easy sums in the first four simple rules of arithmetic.—11. She must bring written proof from the medical officer or officers of some hospital or workhouse infirmary of having acted as a nurse there to his or their satisfaction for a period of three months, or from some duly qualified medical practitioner of having been engaged for six months under proper medical supervision in attendance on the sick at their own homes. She must bring written proof of having been a midwifery pupil for three months in some lying-in hospital, where instruction is given by the medical officers, or in the lying-in ward of a workhouse for six months, or of having attended under the supervision of some medical practitioner or registered midwife at least twenty-five labours.—12. She must pass the required examinations.—13. An examining board for midwives shall be appointed in each registration town throughout England and Wales.—14. The board shall consist of the senior medical officer of health for the town or district, *ex officio*, and of four other medical practitioners, of whom two shall, if circumstances will permit, be the two senior medical officers of the lying-in hospital, hospital, infirmary, or dispensary in the town, and the other two the two senior medical practitioners in the town or registration district, their seniority being determined by the date of their registration as medical practitioners. If any of these four shall be wanting, or shall decline to serve, the remaining members of the board shall fill up the vacancies from practitioners in the town or registration district; and if all four shall be wanting, or shall decline, the vacancies shall be filled up by the senior medical officer of health.—15. Three must be present to form a quorum.—16. The examination shall be partly written, partly oral. The object of the written examination shall be to ascertain that the candidate is possessed of a moderate elementary education. The oral examination shall be the test of professional knowledge: but it shall be in the power of the examiners, when they see fit, to propose questions to be replied to in writing.—17. This examination shall test the candidate's knowledge on certain subjects mentioned below, and no alteration shall be made in the nature of the examination instituted without the previous approval of the Medical Council, who shall have power from time to time to alter or modify such examinations as to them may see fit.—18. (Suggests the subjects of examination.)—19. The fee for the examination shall be £2. Rejected candidates shall have 30s. of their fee returned.—(The remaining paragraphs refer to the duties of midwives.)

The PRESIDENT asked how far the Medical Act Amendment Bill agreed with the scheme proposed by the Society.

Dr. WEST said that the Bill and the scheme were not contradictory; but the former gave only general principles and did not enter into details. The idea was, that the details in it should be arranged by the Medical Council with or without the assistance of the Obstetrical Society. He thought the registration fee named in the Bill to be too high, and beyond the means of the class of persons who became midwives. There was no provision for those claiming registration on the ground of having acted as midwives before the passing of the Bill. The Society objected to the permissive power to form local boards; it would be inoperative. He thought that the printing and publishing of a complete register would be expensive and unnecessary; local registers would be sufficient, if means were adopted for the identification of the midwives by means of numbers.

Mr. SIMON asked whether, if a midwife were registered for a county, and she went elsewhere, her certificate would still be valid if endorsed with a *visa* on the part of the local authorities. Would a central register be necessary?

Dr. WEST thought that, if local registration were properly conducted, a central register would not be very essential.

Mr. SIMON asked if the proposed removal of midwives from the register on account of malpraxis included cases of simple breach of regulations.

Dr. WEST thought that the proposal referred to cases of brutal ignorance—such as tearing out the intestines and allowing fatal hemorrhage without calling in medical aid. The propagation of puerperal fever by carelessness might also come under the same head.

Dr. QUAIN asked who was to investigate charges of malpraxis.

Dr. WEST said this would be the duty of the local board in each district. He did not think that it would be a serious addition to the duties of the Medical Council to decide on such cases, as they would have received a report made, after thorough inquiry, by the local board.

Dr. HUMPHRY asked whether the plan of appointing examiners proposed in the Medical Act Amendment Bill was not preferable to appointing a board of practitioners in any particular district.

Dr. WEST said that medical men in the country towns would have a large local reputation, and their certificates would be more valued in

the locality than those of practitioners in London. He thought, also, that it would be almost impossible to get men engaged in large practice to travel about the country for the purpose of examining midwives.

Dr. ROLLESTON asked if the duties of the Council with respect to cases of malapraxis would be very onerous.

Dr. WEST did not think that they would. It would be only in grave cases that the Council would be troubled.

Dr. ANDREW WOOD asked if it were proposed to restrict the scheme to England and Wales.

Dr. WEST replied that the Obstetrical Society had referred to England and Wales alone, because its operations were confined to that part of the United Kingdom. But the Society had no desire to restrict the scheme.

Sir JAMES PAGET asked what would be the number of midwives to be registered.

Dr. AVELLING thought that there would be about 11,500 in England and Wales.

Mr. MACNAMARA thought that the scheme could be carried out in Ireland.

Dr. AVELLING said that the Presidents of the Obstetrical Societies in Edinburgh and Dublin had expressed their readiness to co-operate.

After some further conversation, the deputation retired.

*The Medical Act Amendment Bill.*—The Council went into Committee for the farther consideration of the Medical Act Amendment Bill.

On the proposal of Mr. SIMON, seconded by Dr. STORRAB, the section of the report of last year's Medical Acts Committee, relating to the Proposals of the Obstetrical Society with regard to Women acting as Midwives in England, was read. (See BRITISH MEDICAL JOURNAL, June 2nd, 1877, page 680.)

Mr. SIMON said that, as Chairman of the Medical Acts Committee of last year, he was prepared to express sympathy with the general intention of the Obstetrical Society, though he differed from it with regard to some points. The gist of the recommendations of the Committee was to lay stress on local rather than on central action. He thought that the Lord President's Bill tended to impose duties on the Council which it could not well execute. It should not be called on to institute examination-rules, and a system of central registration would be very expensive. There was already very great difficulty in keeping the *Medical Register* correct; there were numerous complaints of errors. Now, a medical practitioner was a tangible object and might be traced; but a midwife, being a comparatively less fixed and less known person, easily escaped notice. The registration fee of £5 mentioned in the Bill would be quite impossible for the class of persons of whom midwives consisted. The Council could scarcely undertake the duties of central registration. It was also suggested that the Council should have a disciplinary authority; but he thought that the local authority should be competent for this rather than the Council, unless the latter had the machinery for holding local inquiries. The responsibility which the Bill proposed to throw on the Council was very great. He moved:

"That the Council adheres to the opinion which it expressed last year, in accordance with what it regards as the general intention of the proposals of the Obstetrical Society, that legislation for the following two objects would be desirable: 'firstly, that means under legal sanction should be provided for giving credentials of qualification to competent midwives; and, secondly, that the lives of women in labour should, as far as possible, be protected from the incompetent.'"

Sir WILLIAM GULL seconded the motion. An attempt on the part of the Council to make examination-rules for midwives would fail. It would be much better to delegate the examinations to medical men practising in the localities, who would be more likely to have knowledge as to the characters, etc., of the women, than strangers coming from a distance. The plan of local examinations, however, should be under the general control of the Council, who might see how it would work, and make any alterations that might be necessary. Local registers would be sufficient for all the purposes mentioned in the Bill.

The motion was carried.

The Committee then proceeded to discuss Clause 24 of the Bill.

Mr. SIMON moved, and Sir W. GULL seconded:

"That the Council, having regard to its own special purposes and organisation, and to the resources of its office, could not undertake to initiate arrangements (which must, for the chief part, be local) for the examination, licensing, and registration of midwives throughout the United Kingdom, nor accept such administrative responsibilities as would attach to any central authority which might purport to act in control of the local arrangements for those purposes; but that the Council would willingly, if so desired, provide examination-rules for

the assistance of administrative authorities, local or central, which might be appointed for the purposes of the law."

Dr. HUMPHRY moved, as an amendment, and Mr. TEALE seconded: "That Section i of Clause 24 be in substance approved."

Dr. FERGUS called attention to the resolution passed on April 13th against the framing of examination-rules by the Council.

Dr. ANDREW WOOD said that the Council had last year reported that a system of registration of midwives should be provided; and the Government had inquired as to the means of carrying it out, and had proposed that the Council should be the controlling power. But he did not think that the Council should be required to originate the details of a scheme.

After some remarks from Sir W. GULL, Dr. ROLLESTON, Dr. A. SMITH, Mr. SIMON, Dr. HUMPHRY, and Dr. QUAIN, the amendment was carried—one member only voting against it. It was then put as a substantive motion, and carried.

The Council then resumed.

*Removal of Names from the Register.*—The Registrar was directed to remove from the *Medical Register* the names of John Baxter Langley (M.R.C.S.Eng. 1843), who was reported by the Secretary of the Royal College of Surgeons of England to have been removed from being a member of the College, in consequence of having been convicted of fraud and sentenced to eighteen months' imprisonment with hard labour; of John Campbell White (M.R.C.S.Eng. 1867, L.S.A. 1868, L.R.C.P. Ed. 1868), who had been convicted of attempting to procure miscarriage and sentenced to five years' penal servitude; and of Owen Patrick O'Hare (M.R.C.S.Eng. 1854, M.D. Qu. Univ. Irel. 1855, L.A.H. Dubl. 1862), who had been convicted of a felony and sentenced to twelve months' imprisonment.

*The Medical Act Amendment Bill.*—The Council again went into Committee on this Bill; and the following resolutions were adopted.

Moved by Dr. HUMPHRY, and seconded by Dr. AQUILLA SMITH:

"That Section ii of Clause 24 of the Bill be in substance approved."

Moved by Dr. HUMPHRY, and seconded by Sir JAMES PAGET:

"That, in the opinion of this Council, it is not necessary that a central register of midwives should be kept, but that there should be local registers, and that the duty of keeping them should devolve upon the authorities having power of government in the several places in which the examinations are conducted."

Moved by Mr. MACNAMARA, seconded by Dr. AQUILLA SMITH:

"That the word 'midwifery' in lines 2 and 5 of Section iii of Clause 24 be changed to 'as a midwife', and that the same change be also made elsewhere throughout the Bill."

Moved by Dr. HUMPHRY, and seconded by Sir JAMES PAGET:

"That Sections iii and iv of Clause 24 be modified in accordance with the foregoing resolution, and that it be provided that a certificate of good character be required in the case of those who present themselves for examination or registration."

Moved by Dr. HUMPHRY, and seconded by Sir JAMES PAGET:

"That Section v of Clause 24 be in substance approved."

Moved by Dr. ROLLESTON, and seconded by Sir JAMES PAGET:

"That the following be in substance an addition to Section v of Clause 24: 'Persons not upon such a register shall not be eligible for public appointments as midwives.'"

Moved by Dr. HUMPHRY, and seconded by Sir JAMES PAGET:

"That Section vi of Clause 24 of the Bill, to the end of the Subsection (i), be in substance approved."

Moved by Sir WILLIAM GULL, and seconded by Dr. ROLLESTON:

"That, instead of Subsection ii of Section vi of Clause 24, the following be substituted: '(ii) The register of midwives shall from time to time, and at least once a year, be printed, published, and sold in the several districts of the United Kingdom, as directed by the General Medical Council from time to time; and copies of these registers shall be forwarded to the Medical Council on the 1st of January in each year.'"

Moved by Dr. HUMPHRY, and seconded by Sir JAMES PAGET:

"That lines 28 to 40 of Section vi of Clause 24 be in substance approved."

Moved by Dr. HUMPHRY, and seconded by Sir JAMES PAGET:

"That, with reference to Section vi of Clause 24, the Council is of opinion that the duty of prosecuting under this Clause should devolve upon the local authorities specified under Section v."

Moved by Dr. ANDREW WOOD, and seconded by Dr. AQUILLA SMITH:

"That Clauses 25, 26, 27, 28, 29, 30, 31, 32, 33, 34 be in substance approved."

Moved by Sir JAMES PAGET, and seconded by Dr. ROLLESTON:

"That the attention of the draughtsman be called to the first and third paragraphs of Clause 22 of the Bill."

Moved by Dr. ANDREW WOOD, and seconded by Sir JAMES PAGET:

"That paragraph 4 of Clause 22 be in substance approved."

Moved by Dr. ANDREW WOOD, and seconded by Dr. PYLE:

"That the attention of the draughtsman be called to paragraph 5 of Clause 22."

Moved by Dr. ANDREW WOOD, and seconded by Dr. A. SMITH:

"That paragraph 6 of Clause 22 be in substance approved."

The Council then resumed, and adjourned.

Wednesday, April 17th.

Dr. ACLAND, President, took the Chair at 2 P.M.

*Deputation on the Medical Act Amendment Bill.*—The PRESIDENT stated that a deputation had been received this morning, at 11 o'clock, consisting of the following gentlemen: Dr. Waters (of Chester), Chairman of the Medical Reform Committee; Dr. Davey (of Bristol); Dr. Wade (of Birmingham); Dr. Stewart (of London); Dr. Leech (of Manchester); Mr. Wheelhouse (of Leeds); Mr. Nicholson (of Hull). They were received by himself and the following members of the General Council: Sir James Paget, Dr. Rolleston, Dr. Pyle, Dr. Storrar, Dr. Andrew Wood, Mr. Macnamara, Dr. Leet, Dr. Apjohn, Sir Dominic Corrigan, Dr. Quain, and Mr. Teale. The PRESIDENT informed the Council that the deputation had fully laid before the members of the Council the views of the deputation as to the constitution of the General Medical Council. Of these, the chief seemed to be, that one-fourth of the Council should be elected by the whole medical profession, one-fourth nominated by the Crown, and one half elected by the medical authorities of the United Kingdom. The number of the Council was not held to be important—that is to say, whether they were more or less than now, or the same as now. Various questions were asked of the members of the Council and replied to. The deputation were informed that the members of the Council present met to receive the statements of the deputation, and to hear their opinions; but that, as the business of the present Session of the Council was mainly the consideration of the Government Medical Act (1858) Amendment Bill, the Council might be unable to discuss, as a Council, so important a subject as that of the reconstruction of the General Medical Council. The deputation might be assured that the members of the Council would consider the statements and arguments brought before them with the utmost attention. The question was one which involved many details as well as large issues.

(A full account of the proceedings is given at page 616.)

*The Medical Act Amendment Bill.*—The Council resolved itself into a Committee of the whole Council, for the further consideration of the Medical Act Amendment Bill; and the following resolutions were agreed to:

Moved by Dr. ROLLESTON, seconded by Dr. PYLE, and agreed:

"That the words of Section iv of Clause 14, 'The examination rules shall provide for the admission of women to the examinations', be approved."

Moved by Mr. SIMON, seconded by Sir WILLIAM GULL:

"That after the words 'to the examinations' in Section iv of Clause 14, the following words be added, 'with such distinctions as may be judged necessary between the cases of men and women'."

Moved by Dr. ROLLESTON, seconded by Mr. TURNER:

"That Subsection (a) of Section iv of Clause 14 run as follows: 'No medical authority who, at the passing of this Act, has not granted a medical diploma to women, shall be compelled to admit a woman to examination for a qualification granted by that authority'."

Moved by Sir WILLIAM GULL, and seconded by Dr. HUDSON:

"That the attention of the draughtsman be drawn to the deficiency of power in the Council to carry out the Act in respect of examination-rules as regards women, in Section iv of Clause 14."

Moved by Dr. ROLLESTON, and seconded by Sir WM. GULL:

"That, provided there be no conjoint scheme in operation in any division of the United Kingdom, or there be no admission of women to examination for a double qualification in such division of the kingdom, it shall be in the power of the Council to establish a board for the examination of women in such division of the kingdom."

Moved by Mr. SIMON, and seconded by Mr. MACNAMARA:

"That Subsection (b) of Section iv, Clause 14, be omitted."

Moved by Dr. ROLLESTON, and seconded by Sir WM. GULL:

"That, in place of Subsection (b) of Section iv, Clause 14, of the Bill, the following be substituted: '(b) They shall secure that in the cases of women desirous of obtaining a legal qualification as practitioners in this country, the medical education, evidence of which is required by the examining board, shall have been conducted entirely apart from that of males. (c) They shall secure that the examination

of female candidates, though conducted by the examining board or boards appointed for the examination of male candidates, shall, nevertheless, be conducted entirely apart from the examinations of male candidates'."

Moved by Dr. ROLLESTON, and seconded by Dr. QUAIN:

"That the following Subsection be added to what is set forth in the foregoing resolution:

"(d) That women who pass any examination giving a legal qualification shall have their names entered on a separate register'."

Dr. ANDREW WOOD required that the names and numbers of those who voted for and against the motion respectively, and of those who did not vote, be taken down.

*Majority*, 10.—Mr. Bradford, Dr. Rolleston, Dr. Pyle, Dr. Haldane, Mr. Macnamara, Dr. Leet, Dr. Apjohn, Dr. Quain, Dr. Fergus, Dr. Hudson.

*Minority*, 8.—Dr. Pitman, Sir James Paget, Dr. Humphry, Dr. Andrew Wood, Mr. Turner, Dr. Aquilla Smith, Sir William Gull, Mr. Teale.

*Did not vote*, 5.—The President, Dr. Storrar, Dr. Scott Orr, Sir Dominic Corrigan, Mr. Simon.

*Absent*, 1.—Dr. Pettigrew.

The following resolutions were then adopted.

Moved by Mr. SIMON, seconded by Dr. ROLLESTON, and carried:

"That the following be added to the foregoing resolution: 'Such separation of names not to imply any difference of legal rights'."

Moved by Dr. ROLLESTON, and seconded by Sir WILLIAM GULL:

"That Sections v, vi, vii, and viii of Clause 14 be in substance approved."

Moved by Mr. MACNAMARA, seconded by Dr. A. SMITH, and agreed to:

"That, in the opinion of this Council, it is not desirable to transfer to the Registrar of the General Medical Council the powers possessed by the registrars of the several Branch Councils under the Medical Act (1858) to register duly qualified persons and to receive the fees payable by such persons for such registration, and that a copy of this resolution be transmitted to the draughtsman of his Grace the Lord President's Bill, with a request that he will reconsider, in the spirit of this resolution, the Registration Clauses of the present proposed Medical Act (1858) Amendment Bill."

Sir DOMINIC CORRIGAN moved, and Dr. AQUILLA SMITH seconded:

"That Section ii of Clause 14 run thus: 'The examination-rules shall not require a candidate to adopt the practice of any particular theory of medicine or surgery'."

The motion was negatived.

It was moved by Dr. HUMPHRY, seconded by Dr. QUAIN, and agreed to:

"That, after paragraph 3 of line 15 of Clause 15, the following be added: 'But that power of withdrawal from such scheme on the part of any of the medical authorities be provided in the event of there not being an examining board in each division of the United Kingdom, as recommended by the Council in its resolution of the meeting on April 12th'."

It was moved by Dr. HUMPHRY, seconded by Sir JAMES PAGET, and agreed to:

"That Clauses 16, 17, 18, 19, be in substance approved."

Mr. SIMON moved, and Sir WILLIAM GULL seconded:

"That in line 19 of Clause 20, after the words 'both sexes', be added the words 'with distinction, if judged necessary, between the diplomas of men and women'."

The motion was negatived.

It was moved by Dr. HUMPHRY, seconded by Sir JAMES PAGET, and agreed to:

"That Clause 20 be in substance approved, but that Subsection ii of Section ii of that clause be altered in accordance with the Council's recommendation as to Subsection (a) of Section iv of Clause 14 of the Bill."

Dr. HUMPHRY moved, Sir JAMES PAGET seconded, and it was agreed to:

"That Clause 21 be in substance approved."

The Council then resumed.

*Disposal of Trust Moneys.*—It was moved by Dr. AQUILLA SMITH, and seconded by Sir DOMINIC CORRIGAN:

"That the following amendments be made in Section xiii of the Medical Act (1858):

"(a.) That all moneys held in trust by the Branch Councils for England, Scotland, and Ireland, and now invested in Government securities, be transferred to trustees to be appointed by the General Medical Council, and that, at the end of every financial year, the

balance to the credit of the respective Branch Councils shall be paid to the trustees aforesaid; save and except that the Branch Council for England may retain, at the end of every year, a sum not exceeding two hundred pounds, and the Councils for Scotland and Ireland a sum not exceeding one hundred pounds respectively, to enable them to pay salaries and other expenses before sufficient registration fees be received.

"(B) That all moneys payable to the respective Councils shall be to the treasurers or registrars of such Councils respectively, and shall be applied to defray the expenses of carrying the *Medical Acts 1858 to 1878* into execution in manner following: that is to say, separate accounts shall be kept of the receipts and the expenses of the General Council and of those of the Branch Councils. Returns shall be made by the treasurers of the respective Branch Councils, at such times as the General Council shall direct, of all moneys received by them.

"The expenses of the Branch Councils shall be defrayed, under the directions of those Councils respectively, out of the moneys so received as aforesaid; and the expenses of the General Council, including those of keeping, printing, and publishing the *Registers and the preparing, printing, and publishing the British Pharmacopæia*, shall be defrayed under the direction of the General Council out of the fund held by the trustees.

"[Note. The provision respecting the percentage rate has been omitted, and the words introduced in this amendment are in italics.]"

The motion was negatived.

It was moved by Dr. ANDREW WOOD, seconded by Dr. PITMAN, and agreed to:

"That the resolutions passed by the Council in Committee be now brought up."

"That these resolutions be in substance adopted, and that they be remitted to the Executive Committee to be arranged in order and transmitted by the Committee to the Lord President of Her Majesty's Privy Council."

*Unqualified Assistants.*—Sir DOMINIC CORRIGAN moved, Dr. AQUILLA SMITH seconded, and it was resolved:

"That, while the Council cannot undertake the duty of prosecuting unqualified practitioners, they, nevertheless, think it their duty to draw the attention of the Local Government Board of England to a practice which, it would appear, exists in England of practitioners in charge of medical relief districts employing unqualified assistants to act for them in the treatment of medical and midwifery cases, tending to the detriment of the public and other evils; and they would suggest to the Local Government Board of England the consideration of the rule in Ireland, that no medical officer in charge of any dispensary district is permitted to have a substitute to perform his duties unless for a limited time, and unless such substitute is fully qualified to the satisfaction of the dispensary boards and with the sanction of the Local Government Board."

*Report of Finance Committee.*—It was moved by Dr. QUAIN, seconded by Dr. AQUILLA SMITH, and agreed to:

"That the following Report of the Finance Committee be adopted."

*Report of Finance Committee.*—The report for 1877 was to the following effect (we omit the tabular statements and the references to them):

"The Finance Committee reports that the income of the General and Branch Councils for the year 1877 has been £6,035 9s. 8d., which is less than the income of the preceding year by £250 17s. 1d. The expenditure for the year 1877 has been £6,684 19s. 3d., a sum exceeding the expenditure of the preceding year by £773 0s. 1d. It will, therefore, be evident that, while the income has been less, the expenditure has been greater than during the preceding year. Comparing the actual receipts with the actual expenditure, there remains a deficiency on the year of £649 9s. 7d.

"The amount of fees paid in 1877 to the members of Council was greater than that paid in 1876 by the sum of £259 7s.; and greater than that of 1875 by £569 2s. This result is due to the prolonged sitting of the Council in 1877, which lasted for thirteen days.

"Another considerable item of expenditure has been that for printing the *Pharmacopæia*, being £488 14s., which, of course, is in progress of being refunded by the sale of the work, and which will ultimately produce a profit. There is, further, an exceptional expenditure of £250 on preparing a general index to the first ten volumes of the Minutes of the Council. The honorarium paid to the late registrar caused another exceptional increase in the expenditure of £210. On the other hand, in reference to the diminution of expenditure, it is very gratifying to observe that the attention called in the report of the Finance Committee of last year to the very large expenditure on general printing resulted in a considerable decrease, amounting, indeed, to no less a sum than £470 17s. 5d.

"During the past seven years the expenditure has, on three occasions, exceeded the income by a sum averaging £783, whilst, on four other occasions, the income has exceeded the expenditure by a sum averaging £1,006 12s. 0½d. Whilst the average income for the last seven years has been £5,798, the average expenditure for the same time has been £5,558.

"Lastly, the Committee would draw the attention of the Council to the fact that, but for the exceptional outlay of sums amounting in the whole to £948 14s., there would this year have been a balance in favour of the income of £359 4s."

"RICHARD QUAIN, M.D., Chairman."

*Preliminary Education and Examination of Medical Students.*—Dr. ANDREW WOOD moved, Mr. TEALE seconded, and it was resolved:

"That the following 'answers from medical licensing bodies to a letter sent to them by the Executive Committee in regard to the preliminary education and examination of medical students' be inserted in the minutes."

The letter sent by the Executive Committee to the licensing bodies was as follows.

The Executive Committee, by a resolution passed at its meeting on October 26th, 1877, ordered "That there be addressed to each of the medical licensing bodies a letter in the following terms":

"The General Medical Council, during the last session, had under its serious consideration the very important subject of the preliminary education and examination of medical students, and came thereupon to the following resolutions:

"(a) That a letter be addressed to each of the examining boards whose certificate is accepted as a test of preliminary education by this Council, directing attention to the complaints which have been made by several of the licensing bodies with regard to the insufficiency of the general education of many of the candidates presenting themselves for their examinations."

"(b) That it be recommended to the various licensing bodies to instruct their examiners in professional subjects to report to them any cases in which decided ignorance in general education has been displayed by the candidates, with the name of the board or boards before which the preliminary examinations have been passed; and that the licensing bodies be requested to transmit such reports to the Registrar of the General Medical Council."

"(c) That it is desirable that the examination in general education be left to the Universities, and such other bodies engaged in general education and examination as may from time to time be approved by this Council, and that it be delegated to the Executive Committee to communicate with the licensing bodies on the subject."

"The complaints referred to in Resolution (a) will be found in the answers from medical licensing bodies to questions proposed to them by the Executive Committee, printed in the General Medical Council's minutes for May 10th, 1877."

"With regard to Resolution (c), it may be observed that it has always been the opinion of the Council that the examinations in the subjects of general education should eventually be left to the national educational bodies, although it was, in the first instance, desirable, and indeed necessary, that special examinations for medical students should be instituted by some of the licensing bodies."

"During the last few years, the opportunities afforded to students of presenting themselves for examination in general education have been largely increased, more especially through the local examinations of the several Universities, which are now much resorted to. Thus, the need of the examinations by the licensing bodies has been greatly diminished; and the Council was thus led to think it desirable that these examinations should now be discontinued."

"Upon this point, the Executive Committee would be glad to learn the opinion of your body, at as early a period as it can conveniently be given."

A copy of the foregoing letter was sent by the Registrar to each of the medical licensing bodies on November 6th, 1877. The communications received in answer thereto were to the following effect.

The Registrar of the Royal College of Physicians of London stated: 1. That the recommendation to the various licensing bodies "to instruct their examiners in professional subjects to report to them any cases in which decided ignorance in general education has been displayed by the candidates" had been adopted by the College; 2. That the College has for many years discontinued conducting an examination on the subjects of general education, in compliance with the wish of the General Medical Council.

The Secretary of the Royal College of Surgeons of England reported that the Council had, on the recommendation of the Court of Examiners, adopted, on March 14th, the following resolution: "That, with respect to Resolution (b) of the General Medical Council, as re-

commended by the Court, the suggestion of that Council be complied with, viz., that the examiners of the College in professional subjects be instructed to report to the Council any cases in which decided ignorance in general education has been displayed by the candidates, with the name of the board or boards before which the preliminary examinations have been passed, with a view to such report being transmitted to the Registrar of the General Medical Council." The Court of Examiners, with the consent of the Council, proposed to defer their consideration of the question referred to in Resolution (7) of the General Medical Council until it shall have been determined by the several medical authorities whether or not it is expedient to hold a special examination in general education under the scheme for an examining board, dated the 1st of May last, agreed to by those authorities.

The Master of the Society of Apothecaries of London replied that the Court of Assistants had decided that, "having regard to the origin of our examination in arts, the success which has attended it, and the esteem in which it is, and has always been, held by members of the medical profession, this Society should not discontinue it, at least for the present."

The Vice-Chancellor of the University of Oxford forwarded the following resolutions of the Committee to which the letter of the Executive Committee was referred by the Hebdomadal Council:

"1. That, as regards the Resolutions (a) and (b), we only examine our own candidates for the degree of Bachelor of Arts, and have, therefore, no observations to make upon those resolutions.

"2. That, as regards the question raised in the subsequent part of the letter of the Executive Committee, it is with much satisfaction that we note the confidence reposed by the General Medical Council in the trustworthiness of our local examinations, as well as our responses, moderations, and final schools, or examinations for the degree of B.A."

On the part of the University of Cambridge, Dr. Paget forwarded the following resolutions, passed by the Board of Medical Studies:

"With reference to Resolution (b), the answer of the board is: 'That all students, before presenting themselves for the medical examinations in Cambridge, have passed the previous examination required by the University of candidates for a degree in Arts, or one of the examinations accepted by the University in lieu thereof, and this test is found sufficient.'

"With respect to (7), the answer of the board is: 'That it is desirable that the examinations in general education be left to the Universities and such other bodies engaged in general education and examination as may from time to time be approved by the Council.'

From the University of Durham, it was reported that, at a meeting of the Senate on December 4th, it was decided to agree to the recommendation of the General Council that the examinations in the subjects of general education by the licensing bodies be discontinued.

The Registrar of the University of London replied that he was "directed to point out that the University of London had from the first insisted upon an adequate general education, tested by its matriculation examination, as the condition of admission to its curriculum of study for degrees in medicine. And as it examined for those degrees none but its own matriculated candidates, it had no experience of the deficiency referred to in resolutions (a) and (b) of the General Medical Council. In view of the adoption of a uniform standard of professional qualification for admission to the *Medical Register*, it seemed much to be desired that there should be, so far as might be found practicable, an uniform minimum of preliminary qualification, and that this should be tested by the national educational bodies, rather than by the medical licensing bodies."

The Royal Colleges of Physicians and Surgeons of Edinburgh made a joint reply. They stated that: "In regard to the resolutions (a) and (b), the Colleges, by their representatives in the General Medical Council, had occasion, at meetings of the Council, to refer to the insufficient attainments in general education of not a few of the candidates who from time to time present themselves at the professional examinations of the Colleges. They are glad, therefore, to find that the Council have taken measures calculated to abate the evil, and have made a recommendation (b, as above) of which they highly approve, and which they have already determined to carry into effect." In regard to Resolution (7), the Colleges stated, for various reasons which were assigned: "That they do not deem it either necessary or expedient to part with a privilege which they consider it important that they should continue to possess, and to abandon a duty which they have always endeavoured to fulfil conscientiously and efficiently."

The Faculty of Physicians and Surgeons of Glasgow also sent an elaborate reply. With regard to Resolution (b), they remarked: "That the procedure recommended would, as regards the licensing body so reporting, be somewhat invidious; and as regards the board so reported upon, it would be unfair, unless the papers on which the report was

founded were also transmitted to the General Medical Council. Even if carried into effect, the resolution could be operative only in extreme cases, and therefore could have little influence in raising the standard of general education among medical students." With regard to Resolution (7), the Faculty suggested: "That a thorough and systematic inspection of the preliminary examinations under the control of the Medical Council, viz., those conducted by the universities and the other licensing bodies specially for medical students, would directly conduce to this end. As these examinations are entirely written, such inspection would be comparatively inexpensive, the personal presence of visiting inspectors not being necessary. Let the General Medical Council call for the production of the printed questions as well as the whole written papers of any examination (and not merely a selection from these papers), and submit these questions and papers to competent judges, either within or outside their own body." The Faculty further assigned reasons for holding that it was not desirable that the preliminary examination of medical students should be left exclusively in the hands of the national educating bodies. "On the ground that the work is as well done by them as it is done by the universities, the Faculty are not prepared to divest themselves, in favour of the latter, of a privilege which they have exercised from a period considerably anterior to the passing of the Medical Act. That they perform the duty carefully and honestly is shown by the comparatively small proportion of those who pass to those who enter for the examination." Further: "It would tend to the disintegration of the extra-academic medical schools, to make it imperative on their students to pass their arts examination under the auspices of the universities."

The Dean of the Faculty of Medicine of the University of Edinburgh replies as follows: "I am instructed to state in reply that the Faculty approve of Resolution (7). With regard to Resolution (b), the examination on general education conducted in this University is of such a character that candidates displaying decided ignorance are rejected, and are not admitted to the examinations on the subjects of professional education."

The Secretary of the Medical Faculty of the University of Aberdeen replied that "the Faculty has, on the whole, little ground to complain of defective general education, and is not aware of any complaints having been made by any of the licensing bodies of deficiency in the general education of candidates who had passed the examination in general education in this University. The Faculty is of opinion that the number of such examinations held by the various licensing bodies should be diminished; that it would be enough were there one such examination in Scotland, one in England, and one in Ireland, in addition to the examinations held by the Universities."

The Clerk of the Senate of the University of Glasgow replied as follows: "The Senate are glad to be able to state that a marked improvement in the general education of candidates for the profession, both as tested by the preliminary examinations and as shown by the quality of the papers at the various degree examinations, has been observed from year to year; and they are of opinion that no good purpose will be served by disturbing the action of the various bodies at present in regard to this matter, in any of the ways indicated by the resolutions. They are also of opinion that it would not be desirable, on the part of this University, to undertake the criticism of, or direct attention to, what might appear to be a defective preliminary examination of any other university or licensing body. Whilst concurring in the desire of the Medical Council to do everything in their power to raise gradually the standard of the preliminary examinations, the Senate are of opinion that this object will be best served by allowing the present arrangements to continue without change."

The Secretary of the University of St. Andrew's stated that, at a meeting of the *Senatus Academicus* held on 12th January last, "Professor Pettigrew reported on behalf of the Medical Faculty that they recommended that the *Senatus* should announce to the General Medical Council that they were of opinion that the preliminary examination in medicine should be continued. This was agreed to."

The Registrar of the King and Queen's College of Physicians in Ireland wrote: "I have to inform you (1) that this College has for many years discontinued holding examinations in preliminary education; (2) that this College has given directions to their examiners to report to them the name of the licensing corporation at which any candidate who shall signally fail in general education passed his preliminary examination, and that such examining body shall be reported by the College to the General Medical Council; (3) that this College is highly in favour of leaving the examination in general education to the universities or such other bodies engaged in general education and examination as may from time to time be approved by the General Medical Council."

The Secretary of Council of the Royal College of Surgeons in Ireland wrote: "In deference to the Medical Council, this Council has

reluctantly accepted the certificates on preliminary education issued by other bodies than their own, the names of which appear to be approved by the General Medical Council, but has done so with considerable hesitation, inasmuch as this Council cannot learn that the General Medical Council has ever taken efficient means to ascertain the character of such examinations. . . . Until assured of the efficient and searching character of such examinations, this Council cannot see their way to adopt the recommendation of the General Medical Council, to the effect that this College should renounce its right to test candidates for its licence as to their preliminary knowledge by its own special Board of Examiners." With reference to the recommendation (β), the President and Council of the College "must decline to impose so invidious a task upon their examiners in professional subjects".

The Secretary of the Apothecaries' Hall of Ireland wrote: "I am directed by the Council of the Apothecaries' Hall to inform the Committee that they must respectfully decline to act upon the suggestions under the recommendation marked (β); and I am further to state that they are not at present disposed to transfer their right of examining medical students in the subjects of preliminary education to the national educational bodies, as suggested under the recommendation (γ), forasmuch as it would necessitate their lowering the standard of education and examination which they have required for the past seventy years."

The Registrar of the University of Dublin reported that the Board of Trinity College approved of the action of the Council with regard to the preliminary education and examination of medical students, and were prepared to co-operate in carrying out the resolution of the Council.

*The University of London and the Medical Acts Amendment Bill.*—On the motion of Dr. STORRAR, seconded by Mr. SIMON, it was agreed that the report of a Committee of the Senate of the University of London on the Medical Act (1858) Amendment Bill, adopted by the Senate of the University at its meeting on April 17th, be received and entered in the minutes. After an elaborate examination of Clause 14, the report stated:—"Your committee, while strongly objecting to those provisions of the Lord President's Bill which give to the Medical Council the power of framing examination-rules either for individual bodies or for conjoint schemes (as to which last they consider the existing powers adequate), not only concur in, but would greatly extend, the power given to the Medical Council in promoting such conjoint schemes; feeling assured that no amendment of the existing Act can have any other than a limited and imperfect action which does not provide for the institution of an uniform system of examination and certification in the three kingdoms, such certification being based on the highest attainable minimum for the 'double qualification'." With regard to the admission of women to the medical profession, "while fully agreeing with the principle already laid down by the Medical Council, adopted in the Russell Gurney Act, and sanctioned in the Bill of the Lord President, that no one of the medical bodies should be required to admit women within its pale, your Committee are strongly of opinion that to any general qualifying examination, whether instituted by a conjoint board of medical bodies or by the General Medical Council, women should have a statutory claim for admission; and that such women as pass that examination should thereby gain a title to be placed on the *Medical Register* as qualified medical practitioners, without being admitted either as graduates of any university or as members of any medical corporation".

*Deferred Communications.*—The following communications were referred to the Executive Committee.

1. A recommendation by the Executive Committee that the Cambridge higher local examinations be recognised.
2. A letter from the Secretary of the Queen's University in Scotland, asking information as to the meaning of the term "national educational bodies".
3. A letter from the Medical Alliance Association, asking the Council to hand over an amount equal to half of the penalties recovered in certain cases of prosecution of illegal practitioners.
4. Letters received from Mr. P. E. McKeon, asking whether, as a licentiate of the College of Physicians and Surgeons of Canada East, he could practise his profession in London.

*Executive Committee.*—It was moved by Dr. AQUILLA SMITH, seconded by Dr. A. WOOD, and agreed:

"That the powers and duties heretofore delegated to the Executive Committee be vested in the said committee until the next meeting of the General Medical Council."

*Votes of Thanks.*—It was moved by Dr. AQUILLA SMITH, seconded by Mr. TURNER, and agreed to:

"That the cordial thanks of this Council are eminently due, and are hereby tendered, to Dr. Andrew Wood for his services as Chairman of the Business Committee during the present session of the Council."

Dr. AQUILLA SMITH moved, Dr. ANDREW WOOD seconded, and it was resolved:

"That the thanks of the Council are due, and are hereby tendered, to the treasurers, Dr. Quain and Dr. Pitman, for their services."

It was moved by Dr. AQUILLA SMITH, seconded by Dr. ANDREW WOOD, and carried by acclamation:

"That the thanks of the Council are hereby cordially tendered to Dr. Acland, the President, for his efficient services during the present session of the Medical Council."

## BRITISH MEDICAL JOURNAL.

SATURDAY, APRIL 27TH, 1878.

### THE GENERAL MEDICAL COUNCIL.

THE members of the General Medical Council were this year called together at an earlier date than usual, in consequence of the introduction into the House of Lords of the Lord President's Bill to Amend the Medical Act of 1858. The discussion of this measure, and of questions immediately arising therefrom, occupied nearly the whole of the seven days' session of the Council: in fact, beyond some formal matters, little else was transacted.

After the President's address, the principal topic of which was the Medical Act Amendment Bill, there were laid before the Council important documents in regard to the Bill drawn up by the English Colleges of Physicians and Surgeons; and subsequently expressions of opinion on the measure were received from the Society of Apothecaries and the University of London. The Senatus Academicus of the University of Glasgow also sent a copy of a petition to the House of Lords in favour of the Bill. The Obstetrical Society of London, through its President, Dr. West, sent to the Council a letter with a copy of the Society's amended scheme for the education and registration of midwives; and Mr. Tomes, President of the Dental Reform Committee, forwarded a letter in reference to the Dentists' clauses of the Medical Act Amendment Bill and Sir John Lubbock's Dental Practitioners' Bill.

Before proceeding formally to examine the Lord President's Bill, the opinion of the Council was first sought on one of the most important subjects treated in it—the establishment of conjoint examining boards. The debate on this subject was opened by Dr. Humphry, representative of the University of Cambridge, who, on the first day of the session, proposed a resolution reaffirming the decision at which, by a large majority, the Council had arrived in 1870 in favour of the establishment of such boards. The discussion, which was commenced in the middle of the first day's sitting, was continued through the second day, and was not concluded till the middle of the third. The principle of conjoint examining boards was supported by the English and opposed by the Scottish members of the Council; and it may fairly be considered that the arguments against them were exhaustively set forth by the opponents of the resolution. The principal arguments which they adduced were, that uniformity of examination was not attainable, and even if attainable not desirable, inasmuch as it would tend to lower the standard of professional education; that the conduct of the examinations by a single board in each division of the kingdom would be a work of excessive difficulty; that an additional examination ought not to be imposed on the students of the Scottish universities, which bodies granted licences to practise in almost equal number with the Scottish corporations; that for many years the Edinburgh College of Physicians has held examinations for a double diploma in conjunction with the Edinburgh College of Surgeons and the Glasgow Faculty of Physicians and Surgeons; and that, by the establishment of a conjoint board in Scotland, the revenue of the universities, the greater part of which is applied to the improvement of the means of teaching, would be seriously impaired. These objections were met by the English members, who further objected to the permissive nature of the Bill in respect to con-

joint boards; while several of them called attention to the danger of Government taking the matter entirely into its own hands and instituting a "State examination" on the continental plan, thereby depriving the profession to a very great extent of its liberty of regulating its own affairs; and Dr. Humphry, in his reply, pointed out that the conjoint boards in Scotland and Ireland should be laid down precisely on the same lines as that for England, but that they should be adapted to the circumstances in each division of the kingdom. Ultimately, Dr. Humphry's resolution was carried by a majority of fourteen against ten; the majority consisting of the President, the whole of the English members of the Council, and two Irish members (Dr. Hudson, Crown nominee, and Dr. Leet, the representative of the Apothecaries' Hall in Ireland); and the minority being formed of the whole of the Scottish members and four out of the six Irish members.

This matter having been decided, Dr. Pitman proposed a resolution objecting to the provisions in Clause 14 of the Bill, which directs the General Medical Council to frame the examination-rules for such conjoint boards as might be formed. He argued that this duty would be better performed by the universities and corporations, who would probably, however, object to being deprived of power in this matter. The functions of the Medical Council should be that of superintendence and control, with the power of making representations to the Privy Council should the necessity arise for doing so. The motion was carried.

The Council considered the Lord President's Bill in committee of the whole Council during several days of the session. Clauses 1 and 2 were approved without discussion; but, on Clause 3, an amendment was proposed by Mr. Simon, and seconded by Dr. Humphry, re-asserting the already expressed opinion of the Council on the subjects of conjoint boards and examination-rules. This amendment was carried by a majority of thirteen against ten. Except that the President did not vote on this occasion, the majority and minority consisted respectively of the same members as formed the majority and minority in the vote on Dr. Humphry's resolution.

In discussing the clause (23) of the Bill relating to Dentists, the Council expressed in general terms approval of the introduction into the Bill of provision for their registration; but disapproval of the proposal that the General Medical Council should be required to originate a scheme of examination-rules. In regard to the registration of foreign and colonial dental practitioners, the Council preferred the clause of Sir John Lubbock's Bill relating to that subject to the provisions of the Medical Act Amendment Bill.

With regard to the clauses providing for the recognition of colonial diplomas and degrees, some discussion took place as to the period of probation which should be required; and it was generally felt that ten years, as proposed in the Bill, was too long. Several motions and amendments were proposed; and ultimately it was decided to recommend the omission of all reference to the time during which a person has been in practice in a British possession after the granting of his diploma. Clause 6, relating to the registration of foreign degrees, was in substance approved. No discussion took place, nor was any proposal made, regarding the registration of foreign degrees obtained for ornamental reasons by British registered practitioners.

Clause 13 of the Bill, which provides that the powers of erasing names from and restoring them to the *Register*, was objected to, principally on the ground that the responsibility of deciding on a charge of "infamous or disgraceful conduct in a professional character" ought to lie on the whole Council, whose proceedings should be publicly conducted, as hitherto. A motion in this sense, asking the Lord President to amend Clause 13 accordingly, was adopted; and it was further agreed that it was desirable that the power of erasing the names of registered practitioners convicted of felony or misdemeanour might be deputed to a Committee of the Council—which might be the Executive Committee.

The discussion on the clause relating to the registration of midwives was prefaced by the reception of a deputation from the Obstetrical Society, consisting of Dr. West, the President, and several members,

who called the attention of the Council to the amended scheme drawn up by the Society, and explained their views. In the conversation on the subject, opinions were expressed on the part of the Society that the fee named in the Bill (£5) was too high; that locally conducted examinations and local registers would be sufficient, and indeed preferable to central examinations and a central register; and that evidence of good character should be one of the conditions of registration. The deputation having retired, the Council reaffirmed its approval of the general intention of the proposals of the Obstetrical Society with regard to the registration of qualified midwives. The provisions of Clause 24 of the Bill were then discussed, and generally approved, with the exception that it was considered that a central register of midwives was not necessary, but that local registers should be kept by the local authorities, copies being forwarded yearly to the Medical Council. The Council also expressed the opinion that an addition should be made to the clause, to the effect that none but registered midwives should be capable of holding public appointments. It was also agreed, with reference to the concluding portion of Clause 24, that the duty of prosecuting midwives for offences should devolve on the local authorities.

The portion of the Bill relating to female practitioners of medicine caused some discussion, which was, however, somewhat limited by the shortness of the time at the disposal of the Council for the present session. The opinion of the Council was expressed by a decided majority in favour of conducting the education and examination of females separately from that of males. It was also decided to recommend that the names of females who obtained qualifications to practise should be placed in a separate department of the *Register*; this not to imply any interference with legal rights. It will be remembered that colonial and foreign practitioners are also to be registered separately.

The remaining portions of the Bill received general approval. An objection was raised, however, to certain portions which appear to deprive the Scottish and Irish Branch Councils of the power of registration which they have hitherto—much to the convenience of the profession in the respective divisions of the kingdom—possessed; and it was agreed that the attention of Government should be called to the matter.

The resolutions of the Committee having been brought up, were formally adopted; and the Executive Committee was charged with the duty of arranging them and transmitting them to the Lord President of the Privy Council. Previously to the conclusion of the discussion on the Bill, a deputation consisting of the President, Dr. Humphry, and Dr. Andrew Wood, waited on the Duke of Richmond before the rising of the Houses of Parliament for the Easter vacation, and laid before his Grace the resolutions that had up to the time been passed.

In connection with the question of the amendment of the Medical Act, Dr. E. Waters, and several members of the Medical Reform Committee of the British Medical Association, had an interview, in the forenoon of the last day of the session, with the President and some members of the Medical Council regarding the subject of direct representation of the profession in the Council. A prolonged discussion took place, an account of which will be found at p. 616.

A resolution calling the attention of the Local Government Board to the alleged employment of unqualified persons as assistants by Poor-law medical officers in England, was proposed on the last day of the session by Sir Dominic Corrigan, and adopted.

A series of communications from the various medical authorities in reply to a letter addressed to them by the Executive Committee, with copies of resolutions passed during last year's session of the Council regarding the preliminary examinations of medical students, were ordered to be entered on the minutes; and several documents, for the consideration of which there was not time, were referred to the Executive Committee.

Having transacted some routine business, and passed the usual votes of thanks, the Council separated after a session of seven da

## MEDICAL REFORM: DIRECT REPRESENTATION OF THE PROFESSION IN THE GENERAL MEDICAL COUNCIL.

IN a preceding number, we have demonstrated that it was mainly through the continued efforts of the Association that the Medical Act of 1858 became law, and that, after the failure of several ministers and members of Parliament, it was not until Mr. Headlam, acting for the Association, carried, on July 1st, 1857, the second reading of his Bill by a majority of one hundred and forty-seven, that Mr. Cowper-Temple took charge of a similar measure in the following session, and the Medical Act of 1858, with the concurrence of Mr. Walpole on the part of the Government, was successfully carried through both Houses of the Legislature and became law. As evidence of the recognition by the Government of that day of the important part played by the Association, the fact of the application by Mr. Cowper-Temple to the President of the Council of the Association for a personal interview, before deciding on the character of the measures to be introduced, was also recorded. A change of Government intervened, but the question of medical reform was not on that account again shelved; the vote taken on Mr. Headlam's Bill was held to be decisive of the necessity for legislation, and the Medical Act of 1858 was passed when the present Prime Minister was Chancellor of the Exchequer. The Medical Act of 1858 was never regarded as other than an instalment in the right direction, all that was at that time practicable; and the attempts at legislation which have since been made by the General Medical Council, by the profession as distinguished from the universities and licensing corporations, but above all by ministers of different Governments, prove the want of some further measure. Let us hope, as the Act of 1858 was passed when the present Premier was Chancellor of the Exchequer, so a really efficient measure of medical reform may become law under the Prime Minister who was the first on his accession to office specially to inscribe "Sanitary Legislation" on his banner—a measure in accordance with the enlightened experience of the profession, and one meeting the needs of the public.

The views held by the Association have always been openly set forth; and as stated in the number of the JOURNAL already referred to, an influential meeting was held in London in 1854, before the passing of the Medical Act of 1858, at which the four great principles on which medical reform was to be founded were laid down.

1. Uniformity of qualification.
2. Reciprocity of rights to practise.
3. Registration of qualified practitioners.
4. The government of the profession by representative councils.

The second and third objects—viz., reciprocity of rights to practise and registration of qualified practitioners—were attained and secured by the Act of 1858. The first and fourth objects yet remain to be realised. Uniformity of qualification has also met with general acceptance. The only means of effecting it are those advocated by the Association; that is to say, the establishment of conjoint boards of examination in each division of the kingdom on the principle of equal fees and equal examinations, which every person entering the profession must in the first instance pass. All who succeed in passing this examination will be at once entitled to be placed on the *Medical Register* as registered medical practitioners, qualified to practise all branches of the profession, and will then be at liberty to graduate at any university, or join any of the colleges, on fulfilling the requirements of the corporation they may desire to join. The formation and working of the conjoint boards of examination would necessarily fall under the supervision of the General Medical Council, which would thus, endowed with greater powers than it at present possesses, become virtually the governing body of the profession. This increased power to be granted to the General Medical Council leads up to the fourth prin-

ciple, for which the Association, supported by the profession, has undeviatingly contended; and—if the long and well thought out reasoning, or, if it be preferred, the instinct of the profession, has proved the Association right with regard to uniformity, reciprocity, and registration—the inference is that the instinct of the Association and the profession is equally unerring in its demand for representation in the General Medical Council.

Before the passing of the Medical Act of 1858, the then Medical Reform Committee was taken into council with the Government; and it is proved on unquestionable testimony that, in the conferences which were then held, the question of the direct representation of the profession in the General Medical Council was not only discussed, but that the non-existence of a *Register* of the profession was the reason why it was deferred. The late Mr. Southam, an active member of the Medical Reform Committee of that day, has more than once distinctly stated that it was only deferred on the understanding that, when the *Register* was formed, representatives on the General Medical Council should be accorded to the profession. The arrangement then arrived at was much in the nature of a compact; but it is on other grounds that the Association claims this representation.

First, the General Medical Council, as at present constituted, is imperfect and marred by anomalies. Its composition was simply the result of a compromise, and on that account, if on that alone, requires modification. In Scotland, the great Medical University of Edinburgh is linked with that of Aberdeen, only second to Edinburgh in importance, in representation, and both together send one representative to the General Medical Council. The University of Glasgow is, in like manner, linked with that of St. Andrew's in representation. On the other hand, the University of Durham, which exercises no important bearing on medical education, and which is dependent on Newcastle-on-Tyne for its medical school, has its own special representative in the General Medical Council. Again, the vote of the Apothecaries' Hall of Ireland counts equally with the vote of the Royal College of Surgeons of England, with its thirteen thousand members, in the decisions of the Council. The representatives of the University of Durham and of the Apothecaries' Hall of Ireland are not elected in the same manner. The representative of Durham is elected by a small number of graduates in medicine and a much larger number of clergymen; the representative of the Apothecaries' Hall of Ireland is nominated by a small number of shareholders, some of them women. The advantages attending variety of representation will doubtless be urged by some as a justification of these anomalies; but then comes the question, How can the presence of these representatives in the General Medical Council be defended when the important provincial school of Manchester, with its noble hospitals and great teaching endowments, the flourishing medical schools of Liverpool, Birmingham, Leeds, Sheffield, and Bristol have no voice in the Council?

These circumstances fully bear out the statement that the General Medical Council is at present marred by anomalies, and also imperfect as containing no representative of the profession and of the great provincial schools.

The next question to be considered is, whether the Council thus composed has worked as well as is desirable. Take only the question of medical reform; the necessity for an amendment of the Medical Act of 1858 has been admitted from the time of its enactment. It was always regarded as a preliminary measure. Admitting this, year after year the question of medical reform has been considered by the General Medical Council, and with what result? The Government of the country asked for the aid of the Council in regard to it. The General Medical Council has discussed it; the British Medical Association and the profession have demanded it, and now, after a period of twenty years, the Council has completely failed to arrive at anything approaching an united opinion. The profession has never wavered; year

after year, it called for the establishment of the conjoint scheme of examination unflinchingly, unswervingly, while the General Medical Council has hesitated and halted, and in its recent session, by the small majority of fourteen to ten, succeeded in carrying a vote in favour of it—a majority of four on a point with regard to which the profession has never doubted. Is not this an indication that the Council would be improved, and its efforts for good increased by the infusion into it of a just proportion of independent members having no corporate interests to serve, no fees of lecturers to protect: independent members elected by the general suffrage of the profession?

The plain question, Why has the General Medical Council experienced so much difficulty in settling so vital a point in medical reform? is at once explained by the undue preponderance of the representatives of the licensing bodies upon it. Seventeen members of the Council exclusively represent universities and corporations, and to many of these the granting of diplomas and the fees of professors and lecturers are the first consideration. An impression is entertained that the carrying out of the conjoint scheme may injuriously affect certain corporations and lecturers connected with them, and hence, it is maintained, the hostility of the representatives of such corporations to the conjoint scheme. The profession holds that an addition of independent members to the Council, elected by the profession as distinct from the universities and corporations, is the only means of balancing this too great influence.

Expression has been given to the opinion that the profession does not evince sufficient interest in the proceedings of the Council. This statement was made in the Council by Dr. Andrew Wood, and was one of the reasons urged by him for the admission of direct representatives.

The discussions of the Medical Council involve a considerable outlay. The President, in his opening address during the recent session, stated it to be about £400 for one day, or about £160 day by day. It cannot be denied that the length of the oft-repeated discussions on medical reform has been chiefly caused by those representatives who have been defending the corporations they represent against the supposed injurious effects of the establishment of the conjoint scheme. The richly endowed universities and corporations contribute nothing to the remuneration of their representatives on the Council. The expenses are entirely defrayed by the registration fees paid by the members of the profession. The Council commenced its labours on a sum of many thousands drawn from the members already in the profession at the passing of the Medical Act. On this ground, also, the profession founds one of its claims to representation.

The Council, as at present constituted, is at variance with the profession, and the Association is of opinion that this unnatural state of things would be changed by the concession of direct representation, which would introduce into the Council men free from all narrowness of spirit, possessing the confidence of those who selected them, and having the general welfare of humanity at heart. None are better judges than students of the merits of those who instruct them. Self-interest, material advantage, too often banish disinterestedness; but the members of the medical profession, in remedying the defects of examination and of education of which they are naturally cognisant, will be conferring an unalloyed benefit on the community.

The principle of direct representation is that which the Association has always advocated. Some have suggested that members of corporations should elect the representative of their corporations on the Council, as being more easily worked; they object to the number of the constituency if direct representation be carried out. The difficulty is in reality groundless, and certainly no greater in England, which would have the largest constituency, than in respect of the Royal College of Surgeons of England, which numbers some thirteen thousand members. The present representative for the University of Cambridge

is elected by all the graduates, numbering upwards of four thousand—a number far greater than that of the profession in Ireland and in Scotland.

The expense of election has also been urged against the proposal; and that of a contested election of a representative of Parliament for any of the universities has been brought forward in illustration. The comparison, however, is far-fetched indeed; the representatives of universities in Parliament are men of high position in the world of politics, men looking for office under Government, and to whom an university seat is of the highest importance. There will be no such struggle for a seat at the Board of the General Medical Council, which offers no opportunity of a distinguished career, and which must always entail pecuniary loss, however much it may be prized as a mark of professional confidence. One thing is certain, that, with a constituency such as that which the medical profession will form, no noisy pretender, no vain self-assertor, will have a chance of election. The great provincial schools unquestionably afford an abundance of eligible candidates.

Space will not permit, on the present occasion, the details of the mode of election: they are fully set forth in the drafted Bill of the Association which has been placed before the General Medical Council. They are similar to a plan worked out in great measure with the late Mr. Graves and Sir J. Gray, M.P. for Dublin (who was also a medical man), and were adopted in a Bill drafted by the *Lancet*.

The Association claims the representation of the profession in the General Medical Council, first, as a right, and secondly, as a means of improving the composition and the working of the Council by balancing the undue preponderance of the licensing corporations upon it.

#### DISARTICULATION AT THE HIP.

TOWARDS the end of 1877, M. Verneuil communicated to the Academy of Medicine in Paris a paper on this subject, with remarks on the operative proceeding and mode of dressing. This paper became the starting-point of a long discussion, in which all the surgical celebrities of Paris have in succession taken part. Disarticulation of the hip, says M. Verneuil in his memoir, will always involve a grave prognosis, on the one hand by reason of the dangers inherent to the conditions which necessitate it, on the other by reason of the traumatic accidents to which it is exposed by reason of the extent of the wound. "Death", he adds, "is sometimes immediate, on the operating-table itself; sometimes rapid in the first five hours; sometimes approximate within two hours. At other times, it occurs after the first seven days, or later. Early deaths are by much the most frequent, ordinarily caused by the hæmorrhage which precedes, accompanies, or follows the operation, and which proceeds not only from the femoral artery, but also from the branches of the gluteal and the sciatic arteries. Later deaths are most frequently the result of blood-poisoning." M. Verneuil then attempts to discover, first, what is the mode of operation most calculated to realise economy of blood; and, second, what is the mode of dressing which affords the best precaution against the accidents of infection. To reduce the loss of blood to its minimum, the best method, according to M. Verneuil, consists first in pushing back into the system the blood contained in the limbs by means of the elastic bandage; then removing the thigh as if one were proceeding to remove a voluminous tumour, by exposing and tying the principal vessels before dividing them. This method of proceeding was followed for the first time by M. Verneuil in 1864. To prevent septicæmia in its diverse forms, acute, chronic, or pyæmic, M. Verneuil considers it essential to prevent the discharges from stagnating in the wound, too favourably disposed to retain them; and useful, if it be possible, to prevent changes in those fluids. Primary union, adopted by all surgeons and held in view by all the inventors of operative methods, is, he considers, unfit to fulfil the two former conditions; it favours rather the alteration and retention of the fluids, even if only in the cotyloid

cavity. It ought, he advises, to be abandoned. For the same reason, M. Verneuil abandons the lateral oval proceeding, and the operation by the anterior flap, which favours retention of the fluids, and prefers an open wound largely exposed, such as he obtains by the "racquet" method. The following are the different stages of this procedure. In the first stage, an incision is made in the skin—a vertical incision from 2 to 2.4 inches, starting from a finger's breadth from below the crural arch; and from the inferior extremity of this is made an incision which crosses obliquely the external surface of the great trochanter, and is continued along the gluteal fold. The second stage consists of opening the sheath of the vessels; preventive ligature of the femoral artery above its bifurcation, and ligature of its two branches *en masse* to avoid the reflex hæmorrhage by anastomosis; and section of the veins between the ligatures. The third stage consists of section with the bistoury of the muscles of the anterior region. The vessels compressed in the muscular interstices are only divided after previous ligature. In the fourth stage, the joint is laid open. The fifth stage consists of division of the posterior muscles and of the vessels with the same precautions. The operation may be terminated in half an hour. The wound is open, and shaped like a hollow cone. As to dressing, M. Verneuil employs small squares of tarlatan soaked in water, on which are applied small feathery masses of charpie dipped in antiseptic liquids, which are covered with a thick layer of cotton-wool. The whole is kept in place by a piece of oiled silk as simply arranged as possible. The dressing (*à la Lister modifié*) is rearranged every morning.

All the surgeons who followed M. Verneuil in the discussion admitted the originality of his method. M. Roche, however, observed that Marcellin Duval had already previously substituted the bistoury for the knife; but his proceeding differed essentially from that of M. Verneuil, in that the vessels were not tied until after the operation. M. Terrillon preferred the external oval method; he compressed the aorta and tied the vessels as he proceeded with the section. M. Richet recommended direct compression of the open arteries by the aid of large sponges, soaked, if desired, in hæmostatic fluids. Two operations performed with these precautions—one in 1850, and the other in 1864—ended both successfully; whilst a first disarticulation, performed in June 1848, resulted in considerable hæmorrhage and the death of the patient in forty-eight hours. M. Trélat compressed the iliac and performed preliminary ligature, or prompt ligature of divided vessels, whilst an assistant compressed the whole base of the anterior flap. As for the posterior flap, "what prevents us," he asked, "from proceeding slowly and applying the hæmostatic forceps to every branch which gives blood?" M. Legouest had three times performed disarticulation of the thigh, and had assisted at an equal number of operations. The first of his patients died at the end of four months; the second, at the end of forty-eight hours; and the third, at the end of fifteen days. In the first and third operations, there was abundant hæmorrhage. M. Legouest advised the prevention of hæmorrhage from the femoral and its branches by employing the procedure by the anterior flap, and tying immediately the vessels which it contains. Having uncovered the articulation, he disengaged the head of the femur; and, separating it from the pelvis, he passed behind it the flat of the knife, so as to divide at the same time the posterior soft parts in front of the hands of an assistant who compresses them, stopping to tie the vessels as they are opened. Finally, M. Lefort was of opinion that the sometimes abundant hæmorrhage which often accompanies this operation is not the principal cause of the rapidly fatal result. This frightful mutilation, by cutting off almost a fourth in weight of the body, carries with the limb a quantity of arterial and venous blood greater than that of which even abundant hæmorrhage may cause the loss. This loss, added to that which occurs by the vessels which the surgeon opens, augments in a formidable proportion the gravity of the operation; and to this must be added the modification which must occur in the hydrostatics of the circulation by the removal of so considerable a part of the body. The relative benignity

of disarticulation in patients whose thighs have already been amputated at a more or less distant time, the successful employment of Esmarch's bandage, and the observations of Joseph Bell at the Royal Infirmary of Edinburgh, have led M. Legouest to insist upon this particular part of the question. The economy of blood deserves, then, the attention of all surgeons in performing coxo-femoral disarticulation; and it follows from the communications of all those surgeons, that it is absolutely indispensable to employ every means capable of lessening loss of blood either as a preventive or definitive means.

M. Gros of Nancy, in reviewing this long debate in the *Revue Médicale de l'Est*, which is the organ of the new University at Nancy, calls attention to the very complete memoir recently published on coxo-femoral disarticulation by Dr. Lünig of Zürich (*Ueber die Blutung bei der Exarticulation des Oberschenkels und deren Vermeidung*, Zürich, 1877). Dr. Lünig, he pointed out, had collected four hundred and ninety-seven observations on disarticulation of the hip, in which the mortality is as high as 70 per cent.; but it has been ameliorated of late years. It is greatest in operations performed for wounds by fire-arms, and hardly better in operations performed for ordinary injuries (71 per cent.); more favourable in operations performed for pathological lesions (42 per cent.); and most so in cases of reamputation (40 per cent.) In two hundred and thirty-nine operations having a bad result, and in which the date of death is exactly known, Dr. Lünig has noted that in 5 per cent. of the cases the patient has succumbed during the operation; in 12½ per 100, within one hour; in 26, within five hours; in 46 per 100, or nearly one-half of the cases, within the first day; in 57 per 100 of the cases, within forty-eight hours; and, finally, in 70 per 100 of the cases, before the fifth day.

---

THE old pupils and friends of Mr. Henry Spencer Smith have set on foot a movement to mark their affectionate sense of his long services at St. Mary's Hospital, and personal kindness to themselves, by a suitable testimonial of regard and affection. Mr. Juler of St. Mary's Hospital is the honorary secretary.

A FUND has also been commenced by the old pupils and friends of Mr. Edwin Canton at Charing Cross Hospital for a similar purpose, in connection with his retirement from office.

WE regret to hear this week of the death of Mr. Thomas Carr Jackson of the Great Northern Hospital, an active and able surgeon, who had achieved a good professional reputation and a large measure of success, and has died prematurely, with painful disease of the prostate and bladder, at the age of fifty-two.

MANY London men will also hear with great regret of the quite sudden decease of Mr. Arthur Noverre, a general practitioner in large fashionable practice at the West End, who had only comparatively late in life acquired his London connection, but had made himself more than usually liked and respected by his gentleness of character and the high professional standard by which all his opinions and actions were guided.

THE odour of iodoform is so pungent as to be an objection to its use for the purposes of treatment, in cases in which it has recently been recommended by writers in our columns. *L'Union Médicale* states that, on dissolving it in ether and applying to the diseased parts, on evaporation an odourless coating of iodoform is left.

A TRAMP in Pennsylvania has recently inoculated numbers of individuals with syphilis. He made a vocation of tattooing; and during the process, in order to wet his needles, put them into his mouth, which was full of sores. Measures were taken to have the man arrested, and he freely acknowledged that he was in the tattooing business, but did not know that he had done any harm.

THE *Canada Medical Record* mentions that Dr. Craig recommends a twenty-grain solution of chlorate hydrate for the painless removal of warts.

DR. J. DANIEL MOORE, of Lancaster, has been appointed Visitor of all Houses Licensed for the Reception of Lunatics within the West Riding of Yorkshire, in place of Dr. E. Denis De Vitre, who has resigned.

DR. DA COSTA of Philadelphia reports that he has used hypodermic injection of dialysed iron in chlorosis with most gratifying results. He injects fifteen to thirty minims of the pure liquid daily, with no bad effects whatever.

THE Pharmaceutical Society has just issued an excellent catalogue of their fine *Materia Medica* Museum; it is compiled by the curator, Mr. Holmes, and is full of useful material. Students (and lecturers) who have not always access to very complete collections in our hospital schools, will find the quality and arrangement of the specimens in Bloomsbury Square such as to amply repay study.

AT this week's meeting of the Clinical Society (Friday, April 26th), the following papers will be read: Dr. Tilbury Fox—*Cacotrophia Folliculorum*; Dr. Barlow and Mr. Marsh—*Ovariectomy in a Girl aged 12*; Mr. Barker—*Wound of an Abnormal Obturator Artery in an Operation for Femoral Hernia*; Dr. Barlow (for Dr. Sangster)—*Urticaria Pigmentosa* (living specimen).

#### CHLOROFORM IN LABOUR.

M. LUCAS-CHAMPIONNIÈRE, one of the younger generation of French physicians, who are freeing the school to which they belong from the reproach of neglecting the progress of the medical sciences and medical practice in other countries, has attracted much attention lately to the neglect of chloroform in labour by the French school of accoucheurs. Unaware of the absolute safety of chloroform anæsthesia in labour, demonstrated now in this country and America until it has become a commonplace of experience in untold thousands of cases, French accoucheurs have either ridiculed, denounced, or neglected this precious means of ease and safety, which has proved so immense a boon in easing the pangs of childbirth. French women have no reason to be thankful to them for this neglect. Dr. Campbell, in Paris, has in vain sought to urge the English practice upon the attention of the great body of French accoucheurs. M. Lucas-Championnière seems likely to be more successful; and his able advocacy, and the statement of his experience at the Hôpital Cochin, seem likely to popularise a practice which experience has rendered in other countries as general as it is safe and beneficial.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE following are the names of members nominated by the Council, and proposed to the College for election to the fellowship: John Sykes, M.D. Edinburgh, Doncaster; Thomas Goy, M.D. Heidelberg; John Louis Wm. Thudichum, M.D. Giessen; Arthur Ernest Sansom, M.D. London; William Orange, M.D. Heidelberg, Broadmoor; Alfred Wiltshire, M.D. St. Andrew's; David Lloyd Roberts, M.D. St. Andrew's, Manchester; Charles Henry Ralfe, M.D. Cambridge; John Mitchell Bruce, M.B. London; William Henry Allichin, M.B. London; John Curnow, M.D. London; Alfred Lewis Galabin, M.D. Cambridge.

#### AN AFFLICTED POPULATION.

IN a report lately submitted to the Prefect of the Seine, the following startling disclosures were made. Amongst the population of France, which is estimated at 36,000,000, it has been discovered that there are 37,927 blind and 29,512 deaf and dumb; that is to say, there is 1 blind person to 950 inhabitants, and a deaf and dumb to 1,212. The proportion of lunatics is also considerable. Of 24,456 insane persons, Paris alone contains 7,333.

#### MEDICAL ETIQUETTE.
